MECHANICS' MAGAZINE.

LONDON, FRIDAY, JULY 3, 1863.

STEAM FIRE-ENGINES.

It is difficult to imagine anything more likely to interest the population of a large city than the means of extinguishing fires. The vast destruction of property, the fearful peril to life and limb, the misfortune and misery which attend an extensive conflagration, all tend to place such events in the first rank as fearful calamities. It is a little strange, then to find, that the number of inventions for machines intended to extinguish fires—or fire-engines, in fact—is very small, and that, almost without exception, patents for such contrivances have all been taken out within a very few years. It would be a mere waste of time to discuss the causes which have led to this sufficiently remarkable result; perhaps it arose from the necessity of employing very simple machinery, which afforded little or no scope for that inventive faculty which impels individuals to the Patent-office; perhaps, because the employment, and purchase of such machinery, rests with particular individuals or companies, not with the general public. Suffice it to say, that until within the last thirty or forty years, very little indeed has been done towards supplying cities, ships, or public buildings with trustworthy machines capable of throwing a quantity of water, large enough to be useful, on burning materials.

Nevertheless, the invention, or rather the application, of forcing pumps to the extinguishing of fires, dates back as far as the year 1518, when the existence at Augsburg of a machine of the kind is mentioned. Schott, a Jesuit, describes an engine constructed at Nuremburg in 1657. It was placed on a sledge, drawn by two horses; and, when worked by twenty-eight men, threw an inch jet 80 ft. high. We find the first mention of an air vessel about the year 1699. Leather hose was introduced by Van der Heyden, of Amsterdam, about 1670.

It is very difficult to determine accurately the date of the first employment of any of these machines in London, nor is it indeed a matter of any moment. We may reasonably presume that they were introduced here very soon after their invention on the Continent. All the rest is hidden by the veil of time. About a century ago Mr. Newsham was the principal London builder, and during the last century the fire-engine met with slow improvement from different hands, until about thirty years ago, when Mr. Braithwaite constructed the first steam fire-engine of which we have any record. From the stimulus thereby given to the subject, and the attention it received, the very happiest results have followed; and the fire-engine, from being a miserable hand squirt, has become a magnificent steam pump, whose capacity for elevating water must be measured by the ton, rather than the gallon. Mr. Braithwaite's engine weighed about 6,000 lb. had an upright boiler of about 6-horse power, required twenty minutes to raise steam to a working pressure, and was capable of throwing 150 gallons per minute 80 to 90 ft. high, the steam and water pistons on the same rod were respectively 7 in. and 6½ in. in diameter, with a 16 in. stroke.

But it most certainly is not to the Old World that we are to look for the most prominent records of improvement in this department of hydraulic engineering. Although England took the initiative, and produced the first steam fire-engine, America is entitled to much of the credit of developing the system. Nor is this to be wondered at, when we remember how much more prevalent fires are in the cities of the New World than here. The inflammable nature of the building materials employed, the intense heat of summer weather, and perhaps, a certain amount of recklessness and disregard of proper precautions, are all predisposing causes which conduce strongly enough to conflagrations which demand the employment of the most strenuous means for their extinction. Thus, steam fire-engine building has become as much a department of trade and engineering in North America, as the manufacture of locomotives has in England.

To enter at large into the history of steam fire-engines is foreign to our purpose; but examples of what they have accomplished during the last few years are interesting, as affording a means of comparison both with their present and future performances. The first credit for their successful construction in America, is doubtless, due to Mr. Latta, of Cincinnati, who turned out his first engine in 1853. This ponderous machine weighed not less than 12 tons, and required the tractive force of four horses to aid its progress, although styled a self-propeller. The boiler had a square fire-box, with a continuous coil of tubes in the upper part, through which the water was constantly driven by a circulating pump when the engine was in motion. The time ordinarily taken to get up steam was five to ten minutes, the coil of tube being kept empty till almost red hot, when the action of the circulating pump, by filling it with water, already nearly boiling from contact with the sides of the fire-box, quickly produced sufficient steam to start the engine. Subsequent engines, by the same maker, were considerably improved and reduced in weight; one of them, weighing 8 tons, is said to have thrown an 1½-in. jet 300 ft. horizontally.

At a grand trial of steam fire-engines which took place at Boston in August, 1858, four engines were entered for competition—the "Philadelphia," the "Lawrence," the "E. Smith," and the "New Era." The weight of these engines varied from 7,500 lb. to 9,500 lb.; the time of raising steam to 60 lb. from 10½ minutes to 18½ minutes; the quantity of water thrown by each was 306, 302½, 309, and 345 gallons per minute, to horizontal distances of 163, 155, 140, and 135 ft., and to vertical heights of 110, 110, 125, and 90 ft., the greatest steam pressure being limited to 120 lb. on the square inch. All these engines had upright tubular boilers and reciprocating pumps.

Silsbee and Co. introduced engines very different in construction and arrangement from anything we have in England. The boilers being horizontal, rectangular, and forming the bed-plate for the machinery, both the engine and pump are rotary, and in a certain sense without valves. The steam has been raised in 6 minutes, a small fan being employed to urge the fire; and the entire arrangement is considered very satisfactory in its results and practical working.

The pages of the MECHANICS' MAGAZINE have, from time to time, recorded every improvement which the fire-engine has received in England; a recapitulation of these facts is, therefore, unnecessary here; and the great trial which took place on Wednesday last at the Crystal Palace has proved, conclusively enough, that, so far at least, our English builders are quite capable of equalling, if not exceeding, anything which American enterprise has yet accomplished in this peculiar branch of steam engineering.

The trial took place, as our readers are perhaps aware, in the Crystal Palace grounds, near the north water temple, one of the broad flights of stone terrace steps supplying an admirable location for the engines, hose, hoods, &c.; the engines being placed on one of the landings, and the hoods and tanks on another higher up. The prizes offered were two of £250 each, and two of £100 each. The hoods were raised 40 ft. above the level of the engines, and at an horizontal distance of about 100 ft. The hoods were very similar to those employed last year in Hyde-park, delivering the water through canvas pipes into tanks below, each capable of containing 1,000 gallons.

Eight engines only competed for the prizes; the "Manhattan," which came over from New York, per "Great Eastern," having most unfortunately met with an accident, which resulted in the serious, if not fatal, injury of one of the men in charge, as well as effectually placing the engine *hors de combat* for Wednesday's trial at least. The circumstance is the more to be regretted, as the "Manhattan" is considered one of the "crack" American engines; and its trial would have, to a considerable extent, settled the question of relative merits between London and New York fire-engines.

The trial commenced with the fire-engines over 30 cwt. weight, built respectively by Mr. Roberts, of the firm of Brown, Lennox and Co., Millwall; Messrs. Merryweather, of Long Acre; Easton and Amos, Southwark; Shand and Mason, Blackfriars; and the Amoskeag Engine Building Company, U.S. Mr. Roberts' engine has vertical tubulous boiler, with fire tubes passing through the upper water-space, vertical steam cylinder 7 in. diameter, and 13 in. stroke, arranged somewhat on the "table" principle, the fly-wheel being, however, driven by a bell crank motion. The pump is 9½ in. diameter, with two pistons, which approach to and recede from each other, through the agency of a shaft passing right across the pump barrel, carrying links and arms arranged to give a stroke of 3¼ in. to each piston. The stroke of the pump being equivalent, consequently, to 6½ in. for a single piston. The distinguishing feature of this engine is its ability to carry almost every necessary at a fire—ladders, buckets, hand pipes, an immense quantity of hose, and 17 men—in consequence, although really, perhaps, entitled to be classed as a small engine, it was over the prescribed weight, and had to compete with a far more powerful class of machinery, in which, as might be expected, it failed.

Merryweather's engine has steam cylinders 8¾ in. diameter, arranged horizontally, facing two pumps 6½ in. diameter, the same rod being common to both pistons; stroke 24 in. The steam cylinders have piston valves worked by a very peculiar system of screwed rods, no fly-wheel being employed. The action is, in consequence, in some degree, irregular and unpleasant, but not to any serious extent: it injured the quality of the jet, however, rendering it at times fitful and scattered. The engine weighed, empty, about 2 tons 17 cwt.; vertical tubulous boiler.

Shand and Mason's engine has likewise two horizontal steam cylinders 8½ in. diameter, and two pumps, 7 in. diameter and 9 in. stroke, with piston-rods common to both. These rods have slotted cross-heads which give motion to a fly-wheel shaft running across the engine frame between the pumps and steam cylinders. The boiler is upright tubular, the shell formed of Low Moor, welded. The tubes less than an inch in diameter, and nearly 300 in number, are so arranged in groups as to leave four wide water-spaces to permit free circulation, the shell of the boiler can be easily

removed from the fire-box part, permitting easy access to the tubes. The motion was very easy, and the jet thrown extremely close and compact; weight of engine 2 tons 16 cwt.

Easton and Amos's engine has two 9½ horizontal steam cylinders, with 8½ in. stroke, with two sizes of pumps—one 5½ in., and the other 6½ in. in diameter. The arrangement of engine is precisely the same as that of the "Worthington" steam-pump exhibited in 1862, no fly-wheel being employed. The boiler is on the American principle, vertical, with an immense number of water-tubes suspended from the water-space at top. The weight of this engine 2 tons 18½ cwt. empty.

The Amoskeag engine has a nearly similar boiler, and one vertical steam cylinder 10½ in. diameter and 12 in. stroke; a 4 in. pump being placed exactly underneath and worked by the same rod, which has a slotted cross-head, giving motion to a fly-wheel shaft; weight of engine 2 tons 17 cwt. All these engines can play through more than one delivery hose at a time, although on Wednesday they confined themselves to a single jet.

The fires having been laid, the matches were applied by signal at about half-past twelve o'clock; the three English engines had steam in about four minutes, and immediately turned on their blowers. Merryweather had steam of the prescribed 100 lbs. first, raising it to that pressure in 10 min. 25 sec. from the application of the match. Mr. Roberts and Shand and Mason being scarcely a second behind. The American engine, from having no blower, was more tardy; not having 100 lb. steam until nearly seventeen minutes had elapsed; Easton and Amos taking nearly a quarter of an hour. The four larger engines made capital practice, filling their tanks in a surprisingly short time, the race proving as might be expected, very exciting. It was quickly evident that Mr. Roberts was quite over-matched—a fact not to be wondered at when we remember that his antagonists were nearly double his weight; nevertheless, his practice was exceedingly good, his engine working very steadily, and the jet thrown, close and compact. Every precaution was taken to prevent the spray from a jet entering any hood into which another was playing, and the breeze was so slight as not materially to affect the results.

Three engines entered in the light class (under 30 cwt.), the competitors being Messrs. Shand and Mason, Merryweather, and Lee; Shand and Mason's engine has a boiler exactly similar in construction to, but smaller than that already described; the engine and pump are arranged at the back of the boiler, leaving space for a hose reel, &c., in front, accommodation for several men being provided as well. The frame is formed of steel tubes about 5 in. in diameter, in which the firing tools, stand pipes, &c. are conveniently carried. The steam cylinder is 7 in. in diameter, vertical; with an 8 in. stroke. The piston is hollow, weighing only 8 lbs., and has two steel piston rods, giving motion to a pump of the variety known as bucket and plunger; the barrel being 9 in. in diameter with a 6½ in. plunger; within this last descends a connecting rod which gives motion to a fly-wheel shaft. There are many minor points of interest about this engine which we may perhaps refer to again.

Merryweather's engine has one horizontal cylinder working one pump with the same rod: diameter of steam cylinder, 6½ in.; of pump, 4½; stroke, 12 in.; no fly-wheel; the boiler, upright, water tube.

Lee's engine, built by the Amoskeag Company, is precisely the same in every respect but size as the larger one we have already described—weight 30 cwt.; steam piston, 8½ in.; pump piston, 6½ in.; stroke, 12 in. The jets thrown by all the engines were very good, Messrs. Shand and Mason eclipsing all competitors, however, their jet being distinguished by a closeness which carried the water clear into the hood with a shock which threatened its stability.

Subsequently, Messrs. Easton's engine attempted the 18 ft. lift, and, having failed in two attempts, the fires were drawn, and the proceedings terminated for the day.

Some exception has from time to time been taken against the use of hoods as a test in such trials. We, however, imagine that the real question is not the quantity of water which an engine can pass through it, but rather the quantity which it can lodge in a given time in the right place. Any water which finds its way elsewhere must be a positive evil; and we cannot question that that engine which throws a solid condensed stream, be it only 300 gallons per minute, must be far more effectual, and answer the purpose much better, than an engine throwing twice the quantity by fits and starts, by which it is half-wasted in spray.

Yesterday, the experiments were continued, and, instead of the engines endeavouring to fill tanks of 1,000 gallons simultaneously, the competition consisted, in which engine could fill a tank of 18,000 gallons in the shortest space of time. The "Sabrina," after several ineffectual attempts under the superintendence of Messrs. Easton and Amos, had to be withdrawn. Shand and Mason's engine filled the tank in exactly two hours. Messrs. Merryweather's engine executed the same task in rather less than one hour and a-half, the two stoppages arising from the hose twice bursting included. The last engine experimented on, Lee's "Victoria," commenced most favourably, throwing more water than any of its competitors during the time it was at work; but, owing to an unfortunate accident—the breakage of the cylinder lid—it had to be withdrawn ere the tank was half-full.

The "Manhattan," in a convalescent state, mounted, on a perfect American bogie, exhibited its capacity by throwing vertical and horizontal jets, whose volumes gave a good idea of the immense powers of the machine when in thorough working order.

No one considers the *Times* newspaper as an authority on scientific subjects. Indeed, its reporters, when dealing with such matters as trials of machinery, generally exhibit a blissful ignorance of all that on those occasions they ought to know. We would have thought that, ere this, constant detection, and we had almost added ridicule, would have rendered them more cautious. Their report of this trial, however, contains a sneering criticism on American fire-brigades and engines, which at once exhibits the good taste, scientific, and general information of the writer, in a light which shows that the *Times* has yet to learn not only a smattering of mechanical knowledge, but also the art of treating strangers with courtesy. International competitions afford a bad mark for newspaper insolence.

OSCILLATING ENGINES.

The most superficial examination is sufficient to prove that the modern steam-engine is not a creation, but a growth, and this not alone in the development or application of principles, but even in the smallest matters of merely mechanical detail. What we may call the science of construction was little understood a hundred years ago. Our ancestors could build large castles or cathedrals; a good-sized ship was not beyond their powers. Anything, in fact, which depended for success on the laws of statics, and had no moving parts, throve pretty well under their hands; but when it came to machinery, the case was different; and, from a watch to a flour-mill, all was more or less rough, cumbrous, heavy, and ill-constructed. We believe things would have remained in much the same state to the present day, had not the steam-engine exercised such a demand on the skill of our working population. Its introduction, too, opened a wide field for the application of machines, most of which depended as much for success on finish as the engine which was to give them motion. We find in the different forms under which steam machinery presents itself to our notice, an almost perfect record of the progress made by the arts since its invention, and it is highly improbable that anything but the very simplest arrangements, would strike early inventors as capable of general application. Thus, a working beam had been used, centuries before steam was thought of, for pumping and raising buckets from wells; and it was really the best contrivance Newcomen or Watt could possibly have used for the purpose they had in view. Almost the moment, however, that steam was employed to cause rotation, the defects of the beam system became apparent, although it was many years ere a different form of engine was generally employed. We of the latter half of the 19th century will perhaps say that the abolition of the beam was so obvious an improvement, that the inventors of the direct-acting system deserve little credit for originality. Easily said, when, Columbus-like, the egg is made to stand for us already; be this as it may, the oscillating cylinder, at all events, has crept more slowly to perfection than almost any other arrangement.

The first idea of the kind is doubtless due to Richard Trevethick. In a patent dated, March 24, 1802, to Trevethick and Vivian, they describe a vertical sugar-mill worked by an engine on this principle. But they go rather farther with their notions than the known merits of the system would justify us in following; for they propose, that not the cylinder alone, but boiler, grate, and chimney, should all swing on a vertical axis; the fly-wheel axis being vertical also, of course. Their patent, however, includes a claim for a cylinder on the modern principle. The invention met with little notice at the time.

Witty took out some patents from 1810 to 1813 for moveable cylinders. But the first oscillating engines ever really made, were constructed by Aaron Manby, of the "Horseley Works," Staffordshire, in 1821. Many of these engines were set to work with more or less success. The valves seem to have been the great source of trouble; and the difficulties entailed by the want of a good means of regulating the inlet and outlet of the steam proved a powerful obstacle to the more general adoption of the oscillating system, until two 10-horse power engines, fitted with slide valves nearly as now, were erected on board the "Endeavour," a steamboat plying between London and Richmond, by Messrs. Maudslay and Field, in 1828. Messrs. Penn subsequently undertook the construction of this class of engine on the largest scale, and under their skilful hands it has received improvements which cause it to rank as one of the very best forms of paddle-wheel engine we possess; indeed, it is far from improbable that, after a little time, paddle steamers will be fitted with this class of engine exclusively, as its peculiar arrangements are admirably suited to the enormous

cylinders and slow-speeded pistons, which such vessels require. Oscillating cylinders, weighing over 20 tons, are by no means uncommon.

It is a little strange that a form of engine so well adapted to cramped situations has not as yet been employed to any extent to drive the screw. Several geared engines have been fitted with it—the "Great Britain," for instance; but we believe we are correct in stating that it has been very sparsely, if at all, employed to drive the screw shaft direct. We cannot see any objection to its use for such a purpose, for which, indeed, it seems exceedingly suitable, especially on board narrow vessels, where it is difficult to get room for a long stroke or connecting rod. No difficulty should be experienced with the valve gearing; and the cylinders, if horizontal, would of course balance pretty fairly on their trunnions. By such an arrangement, a great deal of weight would be saved in guide blocks, fixed guides, crossheads, double piston rods, &c.; to the amount of many tons, perhaps, in large engines. The whole system has been too well tried on the largest scale, to admit of much doubt of its success on one much smaller, if not less powerful. What we should lose or risk by its introduction for the purpose is not very apparent, and it is quite certain that we should, at all events, gain a long stroke and a light engine; advantages great enough to entitle the question to some thoughtful consideration.

EFFECTS OF VIBRATION ON WROUGHT IRON.

More than twenty years ago, the cranked axle of a locomotive happened to break during the passage of a train from Paris to Versailles. The breaking of a crank-axle is, unfortunately, no very uncommon occurrence; in this case, however, it led to the deaths of nearly one hundred persons. An accident involving such a wholesale destruction of human life engaged universal attention, and the entire array of Continental science was soon called upon for an explanation of the disaster. It was noticed that the fractured part of the axle showed a crystalline structure; and upon this appearance the explanation was founded that the jarring naturally induced in a railway axle through the vibrations caused by the engine and rail led to the deterioration and ultimate destruction of its cohesive properties. The eminent French savant, Arago, considered that the crystallization of wrought iron was only a matter of time, the length of time being in an inverse ratio to the amount of the vibration. Ever since that period the question as to the "crystallization" of iron has been argued and re-argued *ad infinitum*, by scientific and practical men, but without any definite settlement of the matter. Some have altogether denied the fact that any structural alteration in iron is caused by vibration; while others have as strenuously asserted that such a change does take place, accompanied with an actual metamorphosis in the structure of the metal. Several Papers have been read on this question before the Institution of Civil Engineers, amongst which we may mention Mr. Hood's, on the "Changes of Internal Structure of Iron" (Proceedings of the Institution of Civil Engineers, Vol. II., page 180), and Mr. Thorneycroft's on the same subject (Pr. Ins. Civ. Eng., Vol. IX., page 295). In 1850, Mr. T. E. M'Connell, read a Paper on "Railway Axles and their Deterioration," and the discussion that ensued elicited great difference of opinion on this question amongst the members of the Institute. The late Robert Stephenson controverted the assertion that iron was liable to crystallize, or to change its molecular structure, through vibration. He instanced the Cornish engine beam with a strain of 56 lb. per inch, and, nevertheless, "working eight or ten strokes per minute for more than twenty years;" and the connecting rod of a locomotive vibrating eight times per second for several years, "making more than 200 million times altogether, but the iron retained its fibrous structure." Mr. Slate stated that he had "made a machine in which he put an inch square bar, subjected to a constant strain of 5 tons, and an additional varying strain of 2½ tons, alternately raised and lowered by an eccentric 80 or 90 times per minute, and this motion was continued for so long a time that he considered it equal to ninety years railway working, but no change whatever was perceptible, and, therefore, he was one of those who did not believe in a change from a fibrous to a crystalline structure." Now, with all deference to such an authority as Robert Stephenson, it appears to us that the connecting rod of a locomotive is in a very different condition as regards jar and vibration to the cranked wheel or axle driven by the rod. There is no absolute jar on a connecting rod *working under ordinary circumstances*, and where the engine is properly balanced the rod suffers very little vibration. With the wheel and axle, however, the case is very different. There is a continual jarring—what may be termed a true jar—produced by *metal hammering on metal*. The inequalities of the permanent way, and the various oscillations of the engine and carriages must cause a very powerful and continued vibration of the locomotive and other axles. In the case of the Cornish engine there is none of the jar produced by the impact of metal on metal. This was also absent in Mr. Slate's experiments. We have noticed that the long-continued "chipping" of cast iron with a chipping chisel will often cause the head of the hammer to break in two, especially if the hammer be not struck truly on the chisel head. Here we have a somewhat similar case to that of a wheel on a badly kept permanent way.

There is one very common form in which iron is used that is peculiarly favourable to the development of this jarring action. The different links of a common chain or cable have a continual tendency, when in use, to rattle and strike against each other. The iron forming a chain is necessarily cut up into a number of different parts, which are often obliged to reciprocate each other's blows while the chain is performing its duty; and, in addition to this, chains are often exposed to sudden and powerful tensions. We thus find that the greater number of complaints as to structural alterations in wrought iron have pointed to chains. Mr. M'Connell, while speaking on "Railway Axles and their Deterioration" at the Institution of Civil Engineers, 1850, mentioned that another striking instance of the conversion of tough wrought iron into a brittle material is shown in the chain slings used for carrying the bars during the process of hammering at a forge. "He had lately an opportunity of observing a chain which had been in use for this purpose, and had become so extremely brittle that it was more like glass in its fracture than the strong tough iron which it had been when first made; and he was satisfied that it had only been subjected to this extreme jarring action for a few months, and had not been otherwise applied." The chains used on inclined planes are also stated to break very soon. It is notorious that the crane chains used in engineer's shops almost always become brittle after being two or three years in constant use; their original condition is, however, restored by annealing. The chains used in drawing the "stuff" in the Cornish mines are generally withdrawn from the shaft after six months' use. They are then rolled in a heap, and covered with a sort of cylindrical furnace, and brought to a red heat. This operation is intended to do away with the effect of the vibration. Several of the witnesses before the 1860 "Select Committee on Anchors and Chain Cables for the Merchant Service," recommended a similar operation for the chain cables of ships, to be repeated periodically in conjunction with a system of re-testing. This deteriorating process in cables is so fully acknowledged by practical men, that Mr. T. M. Gladstone, in his evidence before this committee, even put a numerical value upon it, and stated that the chains of a light vessel which are constantly at work would deteriorate at the rate of 10 per cent. in two years. In ordinary cases, the deterioration of the iron would amount to 5 per cent.; and "it would be continuous, until the chain would ultimately break as short as a pipe stem." The instances we have cited are thus drawn from the experience of the workshop, the forge, the mine, the railway, and from seafaring life; and the concurrent and universal testimony of those whose lives—daily and hourly—depend on iron, certainly points to the fact that iron is rendered brittle by vibration or undue tension, perhaps combined with other causes, such as deflection, or any sudden chilling through frost, or by contact, while heated, with cold water.

The theories propounded to account for these molecular changes in iron have been very varied and numerous. Until the experiments lately made by Mr. Kirkaldy on wrought iron and steel, it was generally assumed that a crystalline structure, like that of cast iron, was induced in wrought iron by means of its gradual deterioration through the causes mentioned above. Mr. Kirkaldy has, however, shown that a crystalline appearance is the invariable result when wrought iron is *suddenly* broken; when *gradually*, a fibrous appearance is the result. He appears to consider that this observation has settled the question—as a crystallized fracture can be induced in any iron, the crystallized appearance noticed in iron after it has been in use is merely due to its sudden breakage. Now, as all his experiments appear to have been made on new iron; on "pieces taken promiscuously from engineers' or merchants' stores, except those marked *samples*, which were received from the makers," the question as to the gradual deterioration of iron while under the influences of wear and tear is still as far as ever from a solution. It would, no doubt, be difficult to adduce "conclusive proof that the iron which is produced of a crystalline character was once fibrous." Perhaps the only way would be to subject a tested bar to a true percussive action through some time, and to then test the resulting diminution of tensile strain. The experience as to iron undergoing a gradual deterioration under certain circumstances is too universal to be discredited. The multitude of theories put forth to account for it bear witness to the fact, although an explanation of the phenomenon is still required. Mr. Hood, in the Paper we have alluded to, ascribes the changes in iron to the conjoint action of "percussive heat and magnetism." Mr. Thorneycroft ascribes it to deflection. Some adduce magnetism alone as a principal cause; others point to the original impurities in iron, such as sulphur, phosphorus, arsenic, &c. Mr. Roebling, a distinguished American engineer, assumes that the drawn-out fibre of wrought iron is "composed of an aggregate of

pure iron threads and leaves, enveloped in *cinder*." Wrought iron thus becomes brittle under long-continued vibration under tension, "*because the iron threads and laminæ become loosened in their cinder envelopes*."

There is no doubt, also, that the question has been complicated by many specimens being originally weak, either from defective quality or from being burnt in the forging. The fact seems to be that we are very ignorant as to the ultimate molecular structure of iron, or, indeed, of any other substance. Why does the presence of a percentage of carbon, more or less, exert such a mysterious influence on the cohesive powers of iron? We may never know much more about molecular structure until, in combination with experiments such as those of Mr. Kirkaldy, a powerful microscope shall have been used to investigate the structure of the specimens. It is difficult to believe that a change in tensile strength is not accompanied with a change in molecular structure. Robert Stephenson pointed to the use of the microscope for examining the differences in fracture of so-called crystalline and fibrous iron. He stated that, under the microscope, there was no difference between a fibrous and a crystalline specimen of iron.

We are inclined to offer a fresh explanation of the deterioration of iron under vibration, and of the partial restoration of its tensile strength by annealing. Each bundle of fibres in a bar of wrought iron consists of a number of very small crystals. We might compare a piece of good wrought iron, properly forged or rolled, to an assemblage of strings, each string being composed of a thread of small crystals. An exaggerated picture could be afforded of this, by imagining a bundle of glass threads. If the iron has been burnt in the manufacture, instead of these threads being continuous, they are broken in different parts of their length. The same effect is produced after a long continued jar; there is a solution of continuity in the fibres—they are shaken apart, and the fibres of the iron threads are broken up into shorter pieces. Deflection will produce a similar effect. Frost, or a sudden chill, will contract the fibres, and they will be pulled asunder. On the application of a low red-heat—the process of annealing—the ends of the crystal threads again come into contact through the resulting expansion. The expansion of the whole mass favours the ultimate coherence of the fibres; and, on contracting, the wrought iron returns to its pristine state—that of a bundle of crystal fibres. Thus, under long-continued vibration—before it receives its *coup de grâce*—it is already partly broken; its intimate structure, inaccessible to the eye or to atmospheric influences, is already partially in fragments. The application of a *gradual* strain to iron thus deteriorated and brittle, would have the effect of drawing out the fibres that were still entire, leaving undisturbed the parts that had already given way in the interior. According to this, it will be evident that the face of the fracture—at a right angle to the axis—of a bar of iron injured by vibration, would show no signs of injury; but if it were possible to examine the structure in a like line parallel to the axis of the bar, it would, perhaps, be seen that the fibre was broken up into pieces of different lengths.

BOILER EXPLOSIONS.

THE management of steam-power in England is a disgrace to the wisdom and intelligence of which we are, as a people, so fond of boasting. The daily journals have become a record of misery and destruction, which seems to extend in every direction where steam-power is employed. Explosion follows after explosion, with a rapidity which is awful, and a destructiveness which cries loudly for the interference of some one who has power to save.

We do not hesitate for a moment to say that the principal cause of such calamities is to be found in the gross negligence, to call it by no stronger term, of those whose business it ought to be to take every precaution, which science and experience dictate as a means of securing the lives in a manner entrusted to their care. We know well enough that, without the interference of some totally uninterested power or influence, the evil effects of this negligence will never be overcome, and therefore we assert that it is high time the Government stepped forward and passed such laws as may lead to the compulsory inspection of boilers. It is all very well to say that the safety of a man's own property, is an influence powerful enough to secure efficient supervision. It has notoriously failed to do so hitherto, and it will fail still, because, however interested the proprietor may be, his task in such a case is necessarily delegated to another, and who can answer for the competency or activity, of the delegate? Besides, it is not in manufactories where this influence is most powerful, that boilers explode most frequently; we find that by far the larger number of these catastrophes occur in our mining districts, where the management of steam machinery is frequently reckless to a degree; perhaps because an explosion at the pit's mouth, seldom entails as much destruction to property as if it took place in a mill or a factory.

We are always slow to propose the interference of Government in anything which nearly concerns our trade or manufactures. Arbitrary rules and laws are frequently troublesome and vexatious, but that by no means proves that they are not occasionally necessary. We believe it is necessary for the protection of the public that a law should be passed enforcing the inspection of all stationary boilers, by a well-trained and properly organized staff. Not only does the safety of the men employed about steam machinery demand such a course, but the prevention of the dire secondary calamities which follow on an accident of the kind as well. As an almost invariable rule, we find the works, of which the destroyed steam engine was the moving power, brought to a stand still until the necessary repairs are effected, while numbers are thrown out of bread and become a charge on the parish for a like period.

We are weary of inquests. We cannot see that they are productive of any real good. They fulfil a certain purpose; they occasionally determine (?) the cause of the accident; certain persons are, perhaps, reprimanded, others imprisoned; but they cannot possibly check an evil which we fear becomes daily more extended throughout the land. Science, too, does little for us: is it because there is really no field open for her? While engineers split hairs about the cause of the violence of explosions, they shut their eyes to the fact, that in the miserable condition of boilers will be found the key to half the mischief. Boilers, properly made, not overworked, carefully inspected, and effectually repaired, seldom or never explode. We feel little doubt that a thoroughly well organized expedition of inspection, would bring facts to light, and reveal a state of affairs which would prove sufficiently startling. The engineer, residing in a district where coals are dear and steam machinery valuable, can have but a feeble idea of the phases which boiler engineering presents in districts where coals cost little, and the rudest machinery answers every purpose. Of what avail is it that a boiler has been well made, if that process has taken place thirty years before? Even in the best hands and under the charge of those who are most disposed to exert prudent caution, the report of the Manchester Boiler Association reveals facts sufficiently suggestive. Such associations have conferred a boon on districts; and we earnestly hope that the time is not far distant, when an efficient and rigid Government supervision will answer the same purpose, and fulfil the same ends, for the country at large. In inspection, and in it alone, can we hope to find a remedy for a state of affairs which would be deplorable, were it not disgraceful, and the sooner the necessary work is commenced the better—compulsory, it seems, it must be, and ten thousand times better a compulsory inspection than none at all.

HAWTHORN'S PUMP-VALVES.

MESSRS. HAWTHORN, engineers, Newcastle-upon-Tyne, have recently patented an improvement in pump-valves. The improvements consist in the application of an annular double-mitre-valve to pumps of every description, but specially adapted for the air-pumps of surface condensing engines, or where a free passage, with a small rise or lift, and where a quick action is desirable, as in the case of pumps worked at high speeds, and, further, in the application of a peculiar ball clack or valve, or any number of them, for the same purposes. The double beat or mitre valve first named contains an annular space or ring between the inner diameter of the outer mitre and the outer diameter of the inner mitre of sufficient area to allow the water or other liquid a passage proportioned to the requirements of the pump. The upper portion or lid of the valve is formed of cast iron and wood, the wood

FIG. 1.

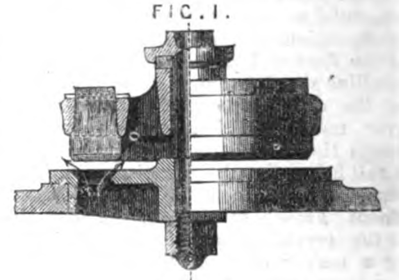

FIG. 2.

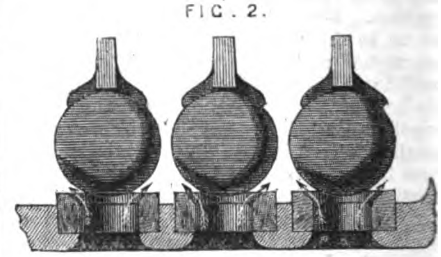

part forming the mitres corresponding with those formed in the annular space in the valve seat. The lid of the valve is guided by a centre bolt of copper or other material with a collar or stop on the top end of it, by which the lift of the valve is regulated, as clearly shown in Fig. 1 of the engravings. The ball clack or valve, shown at Fig. 2, consists of a circular seat of hard wood fitted into a plate forming the bottom of the valve box, upon which a ball falls and closes the passage at each stroke of the pump. The balls may be made of cast iron or other material, either hollow or solid, and the lift regulated by suitable provision.

ROBERTS' FLYER FOR SPINNING FRAMES.

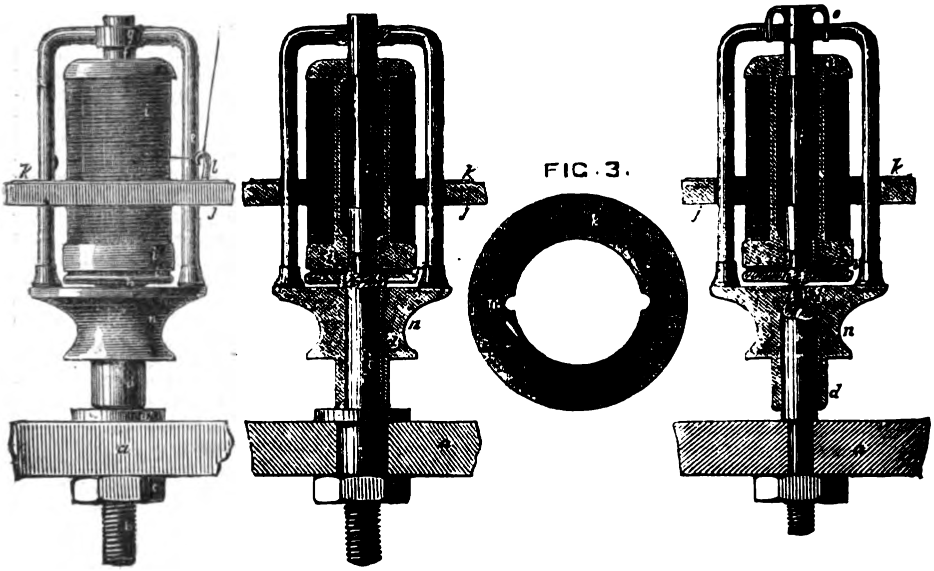

FIG. 1. FIG. 2. FIG. 3. FIG. 4.

ROBERTS' FLYER FOR SPINNING-FRAMES.

A VERY important improvement in flyers for spinning-frames has just been patented by Mr. J. Roberts, of Pendarren House, near Crickhowell, Brecon. The invention is fully illustrated in the accompanying engravings.

The object is to obtain a better "drag" to the thread, yarn, or roving, whilst being wound on to the bobbin, in preparing and spinning fibrous substances, than is usually obtained.

For this purpose the flyer of a preparing or spinning frame is made, somewhat in the form of a parallelogram, the lower side of which may conveniently be a circular or other-shaped metallic plate, which is firmly secured to a neck or socket, and upon this socket a whorl or pulley is fixed. This socket runs upon a suitable stud or pin, which is screwed or otherwise fastened to a strong rail. The flyer is driven by a band from a driving cylinder passed round the said whorl in the usual manner; or it may be driven by any other convenient means. Through the centre of the head of this flyer a spindle is placed, which passes through the bobbin, and prevents it from falling sideways. The spindle is fitted loosely in its bearings; that is to say, the spindle is free to turn in a hole or bearing in the head of the flyer. The lower end of the spindle is also free to turn in a cup or bearing in the stud or pin which supports the flyer and socket, or in a cup in a plate screwed, or otherwise fastened, to this stud or pin, which plate is called the "dead plate." Sometimes the upper end of the spindle is fitted with one or two projecting hooked arms, which, coming in contact with the outside of the flyer head, causes the spindle to revolve with, and at the same speed as, the flyer. The dead plate serves as a base or support for the bottom of the bobbin, and it is by the friction of the bobbin upon this dead plate, or upon appropriate washers interposed between the bobbin and plate, that the "drag" or retardation of the rotation of the bobbin is produced. When the bobbin is to be "doffed," that is, removed from its place within the flyer, the spindle is raised, and the bobbin can then be removed. The spindle not being of much greater length than the bobbin, the bobbin cannot be moved up and down the spindle for the purpose of laying the thread, yarn, or roving upon its whole length, as is done in ordinary spinning-frames; therefore, to provide for the necessary operation of thus laying on the thread, a ring, or other well-known device, is used, which, while it revolves with the flyer, is traversed or moved up and down the flyer by a "lifter rail," upon which the ring rests, or by other convenient means; on this ring are fixed eyes, or twizzles, or loops, through which the thread or yarn coming from the delivering or front rollers of the frame passes on to the bobbin, and consequently the up-and-down motion of the ring with its eyes guides the thread or yarn in a proper direction upon the bobbin. By the compactness of the flyer and spindle, a high velocity in spinning or preparing is obtained, without much shake or "wabble" in this part of the machinery. The "drag" is thus rendered more equable, while, by the peculiar action of the spindle, a more regular and even drag than is usual is obtained.

Fig. 1 is an elevation, and fig. 2 a longitudinal section, of a spindle and flyer, and parts connected therewith, constructed according to this invention. *a* is a rail, to which a pin or stud *b* is screwed by a nut. *c, d*, is a socket or neck fixed to the flyer, and resting upon a collar or bearing d^1, fixed to the stud *b*. *e, e*, is the flyer; *f* is the spindle, the upper end of which revolves in a bearing or circular aperture *g* in the flyer head, while the bottom or lower end revolves in a cup *s*, formed on the top of the stud *b*. *h, h*, is the dead plate, which is screwed on to the stud *b*, upon which the bobbin *i* may rest directly; or, as is represented in the engravings, a washer of cloth i^1, or other suitable material, may be interposed between the bobbin *i* and dead plate *h*. *j, j*, is the lifter rail, upon which a ring *k* rests. This ring *k* is shown detached in plan in fig. 3. It carries eyes or twizzles *l*, through which the yarn passes to the bobbin; it has also nicks *m* cut in it, to fit over the flyer *e*, in order that the flyer, in revolving, may carry the ring round with it. *n* is a whorl or pulley, fixed to the socket or neck *d*, and by which motion is communicated to the flyer through a driving wheel in the ordinary manner.

Fig. 4 represents, in longitudinal section, a modification of the arrangement shown in figs. 1 and 2. In this modified arrangement, the stud *b* is formed conical at top, and the socket *d* cupped to fit over and run upon it, or this conical bearing may be reversed. The bearing surface, and consequently the friction, are much less than when the socket runs upon its base, as in the arrangement previously described. The dead plate *h* is secured to the top of the pin *b* by a small pin or screw, which passes through the top of the socket *d*, but in such manner as not to interfere with its rotation. The bearing *s*, for the lower end of the spindle, is formed in the dead plate *h*. The spindle may be fitted with two hooked arms *o, o*. These arms catch against the head of the flyer, and the spindle is thus caused to revolve with the flyer.

ON THE TRUE THEORY OF PRESSURE AS APPLIED TO ELASTIC FLUIDS.*

By R. MOON, M.A.

IT is the author's object—

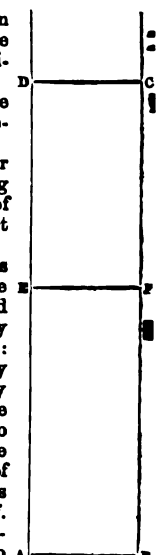
I. To show that, in elastic fluids in motion, or tending to move, it is not generally true, or at least not accurately true, that the pressure depends solely on the density, as is assumed in the ordinary theory of the motion of elastic fluids.

II. To show that, within certain limits and under certain circumstances, pressure may be transmitted instantaneously from one point of an elastic fluid to other points situated at finite distances from the first, before any change has been effected in the density of the intermediate fluid—in a manner analogous to that in which, in the theory of dynamics as applied to rigid bodies, force is assumed to be propagated instantaneously from one point to another.

III. To show that in elastic fluids in motion, or tending to move, the pressure at any point in a given direction will consist of two parts—one depending solely on the density, which will be equal in all directions; the other depending on the state of motion throughout the fluid generally, and which will vary with the direction in which the pressure is estimated. The former of these two constituents the author proposes to designate the statical pressure; the latter, the instantaneous pressure. The true pressure at any point in a given direction will be found by taking the sum or difference of the statical and instantaneous pressures, according to circumstances.

IV. To indicate the manner in which the instantaneous pressure may be represented mathematically.

V. To show the bearing of the proposed correction on the received theory of sound.



A B C D is a vertical cylinder closed at the base A B, and having an air-tight piston C D capable of moving freely in the upper part of it.

Below the piston the tube is filled with air, which at the time *t* is wholly free from impressed velocity, but in which the density varies in the following manner: viz., from A B up to an imaginary horizontal plane E F, the density is uniform; while from E F the density gradually increases up to C D, in such a manner that the effective force at every point of the air between E F and C D is exactly the same, and equal to *f*. Above the piston a vacuum exists. The piston is supposed to have weight, but, for the sake of simplicity, the air under the piston is supposed to be unaffected by gravity. The weight of the piston is supposed to be such that the effective force on each particle of the piston is the same as that on each particle of the mass of fluid E C, viz., *f*.

If the pressure exerted by the air which originally occupied the space A F on that which originally occupied the space E C were to continue during the time t_1 the same that it was at the time *t*, every particle of the former mass of air (which we will designate as the air in A F) would during the time t_1 be under the action of the same effective force *f*, and would therefore in that time describe the same length of path, viz. $\frac{ft_1^2}{2}$; and on this supposition no change would take place in the density of the air in E C during the time t_1. But, according to the received theory, the pressure of the air in A F on that in E C will continue unchanged until the density of the part of the air in A B which abuts on the common boundary of the two masses of fluid has changed. Hence change in the density of the air in A F must precede change in the density of E C.

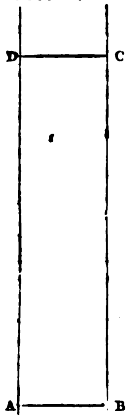
On the other hand, so long as the pressure of

* Read before the Royal Society.

of the air in E C on the air in A F remains unchanged, the air in A F will remain at rest, and will therefore undergo no change of density. But as, according to the received theory, the the pressure of the air in E C on the air in A F depends on the density of the part of the air in E C which abuts on the common boundary of the two masses of air, it follows that change in the density of the air in E C must precede change in the density of the air in A F.

But we have before proved the exact contrary, viz., that change in the density of the air in A F must precede change in the density of the air in E C. It is evident therefore that, according to the received theory, no change can, under the circumstances above supposed, take place in the density of either mass of air.

If, however, the density in A F remain unchanged, we have already seen that every particle in E C will in the time t_1 describe a space equal to $\frac{ft_1^2}{2}$; and if the density in E C remain unchanged, we have equally seen that every particle of A F will have remained at rest during t_1; which is a contradiction. It appears, therefore, that in the case we have been considering the received theory leads us to an absurd result.



It can with still more facility be shown that the received theory leads to an absurd result in the following case:—

A B C D is such a tube as before described; but in the present case we shall suppose it filled below the piston with air of uniform density in equilibrium, the pressure of the air being such as to exactly sustain the weight W_1 of the piston. As before, a vacuum is supposed to exist above the piston, and the air is assumed to be unaffected by gravity.

If a second weight W_2 be placed upon the piston, we know that the equilibrium will be destroyed. But if it be true, as the received theory asserts, that the pressure of an elastic fluid depends solely on its density, the pressure of the air on the lower surface of the piston will be exactly the same after W_2 has been introduced as it was before W_2 was introduced; and, since action and reaction are equal and opposite, whatever be the pressure of the air in the piston, the same will be the pressure of the piston on the air; so that the pressure downwards of the piston on the air beneath will be the same after W_2 was introduced as it was before; and the system therefore will continue in equilibrium after W_2 has been introduced; which is absurd.

By an argument too elaborate to be indicated within the limits of this abstract, the cause of the failure of the existing theory in the instance first above considered is shown; and it is proved that in the second case the effect of the introduction of the weight W_2 is instantaneously to propagate through the air to a definite distance below the piston a finite increase of pressure; such increase of pressure having its maximum immediately underneath the piston, and thence gradually diminishing till, if the tube be long enough, it finally vanishes. The depth to which the instantaneous increase of pressure will extend will be defined by means of two considerations:—1st, that the effected force on every particle of the piston and weight must be exacaly the same as that on the air immediately below it; and 2nd, that the aggregate moving force developed in the piston W, the weight W^2, and the portion of the air in the tube through which the instantaneous pressure extends, must be equal to the moving force developed by gravity in W^2 when free to move *in vacuo*.

It is also shown that if instead of the weight on the piston being suddenly increased it were to be suddenly diminished, exactly analogous results, *mutatis mutandis*, would occur—the effect of the sudden removal of part of the weight being instantaneously to *diminish* the pressure to a finite distance below the piston—such diminution having its maximum immediately beneath the piston, and thence gradually diminishing till, at a certain distance below the piston, the whole pressure will be exactly the same as it was before any part of the weight was removed.

If the piston were wholly removed, the pressure of the air originally in contact with it at the instant of removal would be zero.

It is then shown that the addition to or diminution from the weight on the piston in the case last considered will produce no immediate change in the horizontal pressure in the air below the piston.

It is next shown that in cases where there is no impressed velocity, as in the case first considered in this paper, the instantaneous pressure p_i may be expressed in terms of its partial differential co-efficients, and of the density at the point where the pressure is being considered.

It is also shown that, in the general case, where the whole or a portion of the fluid is endued with velocity, the instantaneous pressure may be ascertained by adding to the expression of the last paragraph a term involving the density and the partial differential co-efficients of the velocity at the point where the pressure is being considered.

It is finally shown that, in the case of the transmission of a pulse through a cylindrical tube where the motions are small, the equation of motion will be of this form—

$$\frac{d^2y}{dt^2}=\frac{a^2d^2y}{dx^2}-\frac{b^3d^2y}{dxdt};$$

where *x* denotes the distance from the origin measured parallel to the axis of a given stratum in the state of rest, *y* the same distance at the time *t*, and a^2 and b^2 are constants, the value of a^2 being the same as in the ordinary theory.

As this equation leads to the conclusion that there are two velocities, it results that, except perhaps in very rare instances, in which a duplication has been observed in sounds heard at very great distances, the proposed correction of the theory of the motion of elastic fluids will not practically affect the theory of sound.

By the method adopted in the case of elastic fluids, the author conceives himself to have established that, in what are commonly termed inelastic fluids, the pressure during motion will not be equal in all directions.

ON INDIAN RIVER STEAMERS.*

In laying before you a few suggestions on Indian river navigation, I will confine my remarks to the river Indus and its tributaries. It is at certain seasons of the year shallow and tortuous, with a current of from 1½ to 3 knots per hour, according to the season—having, like the Nile, periodical inundations. At one place (Sukkur), where a rocky island divides the stream, the current at the high season is from 8 to 9 knots, but this pass is only about three-fourths of a mile in length. There is another peculiarity of the Indus: its shifting channels. It often happens that where there is 8 or 9 ft. water one week, in the following week there will not be as many inches. The banks are also often swept away, taking with them whole native villages, so that any system of buoying off the channel is out of the question.

The navigation is guided by native pilots, who know by the surface of the water the channel to take; and they are often deceived, at times getting into a *cul de sac*, when they must about ship and seek another channel. As to the prospects of trade on the river, I do not think there can be a doubt, as a glance at the map of India will show that it runs through a large tract of well-populated country. At about 500 miles from its mouth it is joined by the Chunab and Sutlej, the Chunab being again joined by the Jelum and Ravee, the Indus holding on its course north until it penetrates the Himalaya mountains and enters Thibet. However, it has not been navigated further north than Attock, and this may be said to be the utmost point navigable. The principal towns are Sukkur on the Indus, Moultan on the Chunab, Lahore on the Ravee, and Ferozpoor on the Sutlej, thus forming the Punjab, or country of the five rivers.

Before describing the kind of vessels I would suggest for its navigation, I will take a review of the vessels that have already been tried. Shortly after the conquest of Scinde by Sir Charles Napier, the East India Company, seeing the advantage of steam, had two small steamers built of light draught. They were 80 ft. long and 18 ft. beam; their load draught was 4 ft., with engines of 50 nominal horse-power. This was a great step from the native boats; but owing to their small power and deep draught of water, they could only take Government stores and a few Government passengers; and, although the distance from Kurrachee to Moultan is only about 800 miles, they generally took five weeks to reach the latter place. The downward passage was accomplished in from seven to ten days. This will even look a long time; but it must be remembered that they can only steam in daylight, laying to at the bank at night, and taking their fuel (wood) for the following day.

They have gradually enlarged the size of their steamers as they built new ones, until the last built, just before India was united to the British Crown, were length 166 ft., beam 28 ft., depth of hold 8 ft., nominal horse power 120, their load draught 4 ft. 6 in. Now the great fault of these vessels was their draught of water and the length of time on the passage, twenty days being their average up passage; and at the high season of the river they could not go through Sukkur Pass, their cargo being unshipped below and transported in bullock carts to the upper side of the pass, and then put on board another steamer.

The next move for navigating the Indus was by a joint-stock company, with a *patent* for navigating shallow rivers. This was a steamer with an articulated train of barges, something like your mud barges on the Clyde, only that the bow of each barge was fitted into the stern of the preceding one, which was part of a circle, and tied together with triangular draw-bars working on ball and socket joints. The steamer was 200 ft. long, 20 ft. beam, and 5 ft. depth of hold. The first or joining barge was 40 ft. long, 18 ft. beam, and the same depth as the steamer. This barge was concave at both ends, so as to join the convex stern of the steamer and convex bow of the following barge. To complete the train, other four barges were joined in a similar manner, 100 ft. long, 18 ft. beam, and 5 ft. depth of hold, the whole train being 640 ft. long. The last barge was for passengers, having a deck-house, 60 ft. by 16 ft. Her stern was spoon-shaped, with a rudder attached. The bow of the steamer was also of the spoon pattern. The displacement of the steamer with engines and boilers was 185 tons, and the mean draught was 2 ft. 2½ in. The joining barge displaced 18 tons, draught of water 10½ in.; each of the 100 ft. barges displaced 39 tons, draught 10 in.; and the passenger barge displaced 63 tons, draught of water 1 ft. 4 in. This was their displacement without any cargo. The train was fitted with a great number of novelties, among which was a self-acting telegraph, to indicate to the steersmen of the other barges what direction the bow of the steamer was taking, the steamer as it were acting as a bow rudder to the rest of the train. On the steamer's bow was placed a frame with thirty lanterns, to throw a blaze of light ahead, to enable them to proceed in the darkest night. The paddle-wheels were six inches below the keel, that they might be used as crawlers when the train had not water to float in, having a supplementary engine, fitted with wheel gearing, to reduce the speed when crawling.

The last barge of the train was fitted with a drop pile. This was to pin the tail of the train if the bow should get aground when going with the stream, and prevent the doubling up of the train. None of these novelties were of much service. Once at Grizree the steamer was crawled off with six inches less water than her draught, but the bottom was a stiff clay. At another time in

* Read by Mr. R. Leys, before the Scottish Shipbuilding Association, March 2nd, 1863—James Hall, Esq., President, in the Chair.

Kurrachee harbour, where the bottom was sand, they just dug a hole in the sand without moving the vessel. The drop pile was once tried, but although it was an elm log 15 in. square, it nipped across like a carrot.

A number of experimental trials were made at a measured distance of 3,850 yards in Kurrachee harbour, the mean results of which were as follows:—With steamer alone, loaded to a mean draught of 3 ft., the speed attained, with an indicated horse power of 273·58, was 9·374 English miles. Her immersed midship section was 58 square feet. This was a very poor result, but from her block stern and formation of the bow little else could be expected. The next trial was with the 40 ft. and one of the 100 ft. barges connected, loaded to 2 ft. 10 in. With this a speed of 7·19 English miles was attained, the indicated power being 302·79-horse power, the immersed section of steamer being the same as on the former trial, the length of steamer and barges 340 ft. Another 100 ft. barge was connected, and the speed was reduced to 5·75 English miles, indicated power 332-horse power. Another 100 ft. barge was connected, thus making the length of train 540 ft. The speed was reduced to 4·33 English miles. The slip of the wheel on this trial was 51 per cent. I may mention that the engines were high-pressure, and the steam carried on these trials was from 90 to 110 lb.

After these trials, the train of steamer, 40 ft. barge, and 100 ft. barge, made an attempt to ascend the Indus; but although the *patentee* was on board, with a crew of thirty-two Europeans and forty-two natives, it was twenty-three days in making 420 miles. It was found quite unmanageable in the currents, oftener in a zig-zag than in a striaght line, first on the one bank then on the opposite. A second attempt was made, which was equally unsuccessful.

After this failure, alterations were made on the steering gear, and a number of trials made in the harbour with no better result as to speed—the steering rather improved. The train again started for the river; but before it was well out of the harbour one of the arms of the draw-bar broke, and the barges doubled round on the steamer, breaking in the stern and after compartment, when the steamer filled and sank in twenty-four feet water, the crew getting on to the barges. No lives were lost. Thus ended the train system, for a time at least, although a second train was ready for launching.

The steamer of this second train had now her block stern cut off, and lengthened 20 feet, with a pretty fine after run; the barges got bows and sterns put to them to suit them for being lashed alongside the steamer, or towed astern, as might be wanted. This steamer started for Moultan with one barge 140 feet long, going through Sukkur Pass at the height of the innundations, and reached Moultan in twenty-five days. This was a poor result, but it was only making the best of a bad job. Since then she has taken two barges and made the passage pretty regularly.

The next move for navigating the Indus was with steamers and railway combined—the Scinde Railway and Indus Flotilla.

The Scinde Railway starts from the Island of Keamaree, which forms the east side of the harbour of Kurrachee, and has its terminus at Kottree, on the banks of the Indus, about 130 miles from its mouth. This line is 110 miles long, and makes a very considerable saving in distance, but much more in time; the shortest water route to Kottree being 230 miles, but can only be used about seven months in the year, the N.W. monsoons causing a heavy surf all along that coast from April to September. The other water passage is by the creeks, which are very tortuous, and the distance to Kottree by them is computed at about 400 miles.

The Indus Flotilla Company had a steamer built on the Thames by a celebrated builder, and tried on that river. Her dimensions were, length 200 feet, beam 38 feet, and depth of hold 8 feet. She was propelled by a condensing three-cylinder oscillating engine, two of the cylinders being below and the third above the deck. At her trial on the Thames she attained a speed of 13 miles per hour, with 688 indicated horse-power; her draught of water was 1 foot 11 inches, and her immersed midship section 70 feet. This was no great result, but it exceeded anything she ever did in India. Whether that her boilers were not suited for wood fuel, or that the heavy teak decks and stringers fitted into her in India, was the cause of her falling off, I do not pretend to say: it might be both combined; but the fact was she did not make over 10 miles an hour in still water when tried in India. She was very unfortunate, breaking one of her piston-rods and smashing a cylinder. There were other six steamers built from this model one, and from my last account only one of them had been tried. The results were so unfavourable that not one of them was taken off the contractor's hands after being put up at Kurrachee, the company having purchased some of the boats belonging to the East India Company, and are carrying on their trade with them.

This is pretty nearly what has been done in navigating the Indus. To know the rock that others struck on was my reason for dwelling so long on what has been done already. It is a great part of the battle to know the dangers ahead.

I will now lay before you what sort of vessels I think would suit that or similar rivers. Light draught is of the utmost importance, combined with strength and moderate speed. To secure the first two qualities, steel or homogeneous metal should be used in the plates, frames, decks, and beams; and from the late improvements in the manufacture of the latter metal, it would not be much more expense, taking into account its smaller scantling for equal strength compared with iron; and further to strengthen the steamer longitudinally, two bulkheads to run from bow to stern, about 6 ft. from her sides, also to be divided into five compartments by thwart bulkheads above the longitudinal bulkheads, two trusses rising about 8 ft. above the deck at midship, with stanchions spaced about 10 ft. apart; the trusses to be of the T-section, and the stanchions tubes for lightness. For the third qualification, high-pressure engines and boilers of the locomotive class, using steel for piston-rods, connecting rods, and valve gear, and homogeneous metal in the framing, shafts, and cranks, cast iron only being used for the cylinders and valve casing; in fact, wherever the superior metal can be used, it should be adopted.

The description of vessels would be a steamer with two barges lashed alongside, or in going through the creeks or narrows to be towed astern. Dimensions for steamer to be, length 240 ft., beam 30 ft., and depth of hold 5 ft., with a co-efficient of fineness at 3 ft. draught of ·72. This will look full, but it must be remembered that it is nearly all taken from the two ends, the body of the vessel for about two-thirds her length being nearly a square box.

The barges to be, length 150 ft., beam 22 ft., and depth of hold 5 ft., co-efficient of fineness ·75, divided into three compartments with thwart bulkheads. The decks to be of the same material as the vessels.

A steamer of the above dimensions would displace at 3 feet draught 432 tons. The hull and fittings I calculate would be 185 tons; engines, boilers, and water, 110 tons; this would leave for cargo and fuel 137 tons, allowing 37 tons for fuel, which would be ample for her longest run between stations. This would leave 100 tons for dead weight cargo of steamer.

Each barge would displace 206 tons at 3 ft. draught. Weight of each 56 tons for cargo to each barge. This gives for steamer and two barges 400 tons of cargo, which, at the present rate of freight, 1d. per ton per mile for up freight, and ½d. per ton per mile for down freight, should leave a very good return upon the capital laid out, after clearing working expenses.

I am quite aware that fulness increases the weight of the vessel herself, and tends to diminish the speed; but I wish to make her an owner's vessel, to carry a fair load upon the least draught of water. Now, I think you will agree with me that fulness has something to do in this respect; and as I do not think it advisable to make her longer for handiness in working in the river, the only other resource would be giving her more beam. This, I think, would increase the resistance as much as a little fulness in the vessel herself. Further, she is finer than any of the steamers on the river when I left. I believe the O. I. S. Company got one or two boats on the model of your Clyde river steamers; but what was the consequence? They drew 4 ft. 6 in., and were therefore useless for a part of the year. Light draught and to carry a fair cargo is indispensable. Speed, such as your Rothesay boats, is not wanted; 11 or 12 miles an hour would be ample, and with 600 indicated horse-power, I think would be realised easily, even taking into account the fulness.

The boats of the Government, with very bluff bows, and 1½ ft. more draught of water, the midship's immersed area being 126 ft. for steamer and barge, made 8 miles an hour with about 400 indicated horse-power. I am taking the indicated horse-power at 2½ times the nominal, and I am sure they did not exceed, if they came up to that; and again the "Sutlej," the altered train steamer, with one barge, went through Sukkur Pass at the height of the inundation, the current at the time said to be 8 miles, and the speed of the vessel 1½ miles per hour. Now, I have uniformly found that a steamer will go in still water more than the current and speed of ship added together. Some allowance must be made for shallow water; but the Indus is neither a shallow nor a narrow river generally: in some parts it is both, though not at the same place, and of course you must have vessels to pass these parts.

The expense of such a class of steamers would be about £450 per voyage for fuel, wages, and stores. The fuel is the heavy item, and as the demand for wood increases, there is no doubt the price will also rise; but as coal has been found in Scinde and also in the Punjab, that will soon become the fuel to be used. English coal might be used for the lower stations of the river; but to transport it to the upper stations would be very expensive, at least £7 per ton for the upper stations before being put on board the steamers. You must not understand that I think that *one* steamer and barges would be a profitable investment. The expense of management, agencies, and fuel stations would be too heavy; these would be the same whether there was one or a dozen of steamers sailing from each end weekly, or at least once in ten days; for this, four or six steamers and barges would be wanted.

The trade of the river is in a transition state, increasing every year to a large extent. The principal up freight is general merchandise, piece goods, beer, and metals; the down freight is raw and manufactured silks, wool, indigo, and various kinds of oil seeds, to which I hope soon will be added cotton.

The passenger traffic is mostly native, and though not yet so numerous as on the Clyde in the summer time, it has increased greatly, and will continue to increase as facilities are afforded them, for they are a very migratory race. Cabin accomodation is not required to any large extent: the natives are all deck passengers, and even the few Europeans that travel prefer what is called a first-class deck passage. This simply means to be victualed in the cabin and sleep on deck.

No bulwarks are required for steamers or barges, but a light rail and netting, with awning stanchions fitted for double awnings, with a space between the awnings of about 18 in.; the lower awning to have hanging curtains all round.

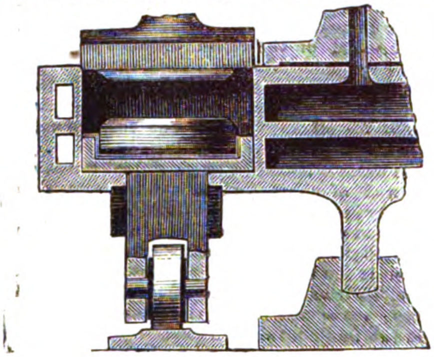
The engines, as I formerly stated, should be high-pressure of the simplest construction. I think diagonal cylinders of about 26 in. diameter and 5 ft. stroke, working steam at 100 lb. per square inch, and cutting off at half-stroke, with a piston speed of 350 ft. per minute, would be a suitable size. Although they take up a large space in the vessel, they distribute the strain to an equal extent. As the water of the Indus is very muddy, a filter is indispensable for the feed water. One placed in the bilge of the vessel,

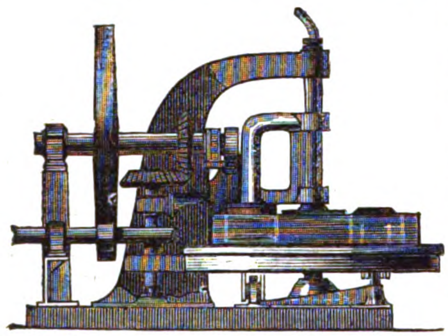
with a steam pipe attached to reverse the current at pleasure, and clean it out, would be suitable.

The boilers to be of the locomotive class, suitable for wood fuel; the furnace doors large, Scinde wood being in crooked billets, generally supplied in from 3 to 4 ft. lengths. The funnel to have a spark catcher similar to those on the American locomotives; the ash pans to be used as feed heaters, with safety escape valve connected to each.

HADFIELD AND ATTKINS' BRICK AND TILE MACHINE.

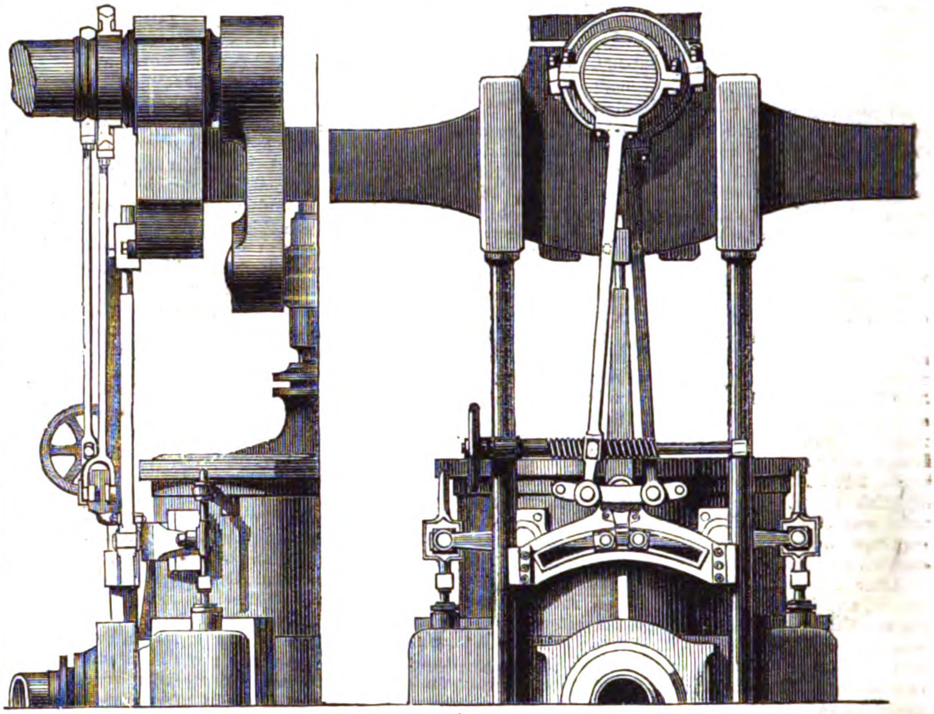
THE engravings show a machine for making bricks and tiles, the invention of Messrs. Hadfield and Attkins, of Hadfield, Derby. The invention consists in the construction and employment of a revolving table or frame, upon or in which any convenient number of moulds open at the top and each fitted with rising bottom dies and pistons (actuated as hereinafter described) are placed, and a rising and falling main piston actuated by a crank, and also working radially into and out of each succeeding travelling mould passing respectively under the said piston as the table revolves. The travelling mould pistons are made





in box form open at the top to receive cushion dies, these pistons form the bottoms of the moulds, in which they are accurately fitted, and are also caused to rise and fall therein more or less as required, and to operate by their upward pressure simultaneously with the downward pressure of the main piston working into and out of each mould as before described. The travelling mould pistons and bottom dies are actuated by two semicircular inclined planes fitted upon a bed plate under the revolving table, upon which inclines the bottom dies and pistons are respectively supported and travel as the table revolves, and are thereby caused to rise and fall in the moulds. The sides of these moulds are made hollow or in double case to receive steam, hot water, or air for heating the same, to prevent the necessity of lubrication. The revolving table and rising and falling pistons of the machine are actuated by suitable gearing driven by a steam-engine, or otherwise; and the bricks, tiles, clay, or other materials, having been thereby subjected to the required compressing forces and having received the desired form, are lifted out of the moulds by the continued rising of the bottom piston along the circular incline, until it arrives at the highest point thereof, when the compressed articles are removed and their places supplied by other materials.

CAIRD'S IMPROVEMENTS IN STEAM-ENGINES.



CAIRD'S IMPROVEMENTS IN STEAM ENGINES.

MR. J. T. CAIRD, of Greenock, has obtained a patent for some improvements in steam engines, The invention, which is illustrated in the above engravings, relates to a novel arrangement and construction of certain mechanically operative details connected with the valvular apparatus or movements of steam engines, more particularly those of the oscillating class.

The improvements may be carried out under various modifications; but, according to one arrangement, as adapted specially to oscillating engines, the details are contrived as follows:—The working steam cylinder is formed or fitted with separate and distinct valve faces; two, for example, for the main working steam slide valves, and two for the expansion slide valves on the steam belt. These valve faces, and consequently their corresponding valves, are disposed two on each side of the main trunnion on which the cylinder oscillates, that is, there is one main steam slide valve and one expansion valve on each side. The expansion valve is placed nearest the trunnion, or, in other words, it is between the trunnion and the main steam slide valve, and it is worked by a double lever arm from the link hereinafter described. This arrangement of the valves forms a good balance, and it enables the expansion to be carried out in a much more effective manner than can be accomplished according to the usual plan. To a segmentally slotted bar or cross-head piece, similar to that ordinarily employed for the communication of the eccentric's motion to the main slide valves, without any derangement from the oscillatory action of the cylinder, there is attached at the centre a cranked stud. This stud is bolted in laterally, and is cranked upwards, terminating in a large eye. This eye is bored out horizontally to embrace a traversing bush, cylindrical in external form, but recessed laterally on each side, or formed with top and bottom shoulders to fit into the expansion lever link. This link is composed of two plain bars or curved segmental pieces bolted together, with a space between them for the traverse of the bush therein. It is from this stud as a centre that the motion of the eccentric is conveyed to the valve. One end of the link is jointed in the usual manner by a fixed stud to the lower end of the eccentric rod from the main shaft, and the link thus receives the vibratory action necessary for the operation of the valve. The opposite end of the link is similarly jointed to the lower end of a pendent radius rod or bar, the upper end of which is fitted with a ring to embrace a concentric collar or shoulder on the main shaft, or fixed to a stud placed as near the centre of the shaft as possible; thus this rod has no longitudinal traverse motion, and its lower end forms the fixed supporting centre for the link to work upon. This lower end is fitted with an adjusting screw, spindle, lever, and link movement or other adjusting arrangement, so that it can be set in or out from the main vertical centre line of the cylinder, and thus vary the effective throw of the link, and consequently alter the expansive action of the valve. This system of valve gear is applicable to all classes of steam engines and valvular apparatus, and it is available as well for the main slide valves as for separate expansion valves. The adjustable radius bar always keeps the centres correct, and forms a steady fulcrum for the link action, whilst its adjustment is so simple that the engines can be handled with much greater facility than heretofore.

A NEW RAILWAY SIGNAL.

TRAVELLERS on the Midland Railway, passing Kegworth, may have observed at that place a new signal which is likely to cause a revolution in railway signals. It consists of a clock, with a face four feet in diameter, placed on the top of a column fifteen feet high. Only a quarter of the clock is shown, which is formed of ground glass, with red figures 0.5.10.15., and has only one hand. Attached to the clock is a long rod connected with a treadle about sixteen feet long, which lies along the inside of one of the rails. On the train passing over the treadle it is depressed slightly by the wheel flange, and the clock hand is set at liberty and is so adjusted by a counterpoise that it turns to the figure 0. Immediately the train has passed over the hand begins again to mark the time up to 15 minutes, when it is stopped, thus indicating to the next train exactly how long up to 15 minutes the preceding train has passed the signal. The same clock works two faces, one for the up and one for the down line. The signal is illuminated at night. The simplicity of this signal is such that it is almost an impossibility for it to get out of order, and it is so arranged that a passing train takes off all pressure from

JEWSBURY'S APPARATUS FOR RAISING WEIGHTS.

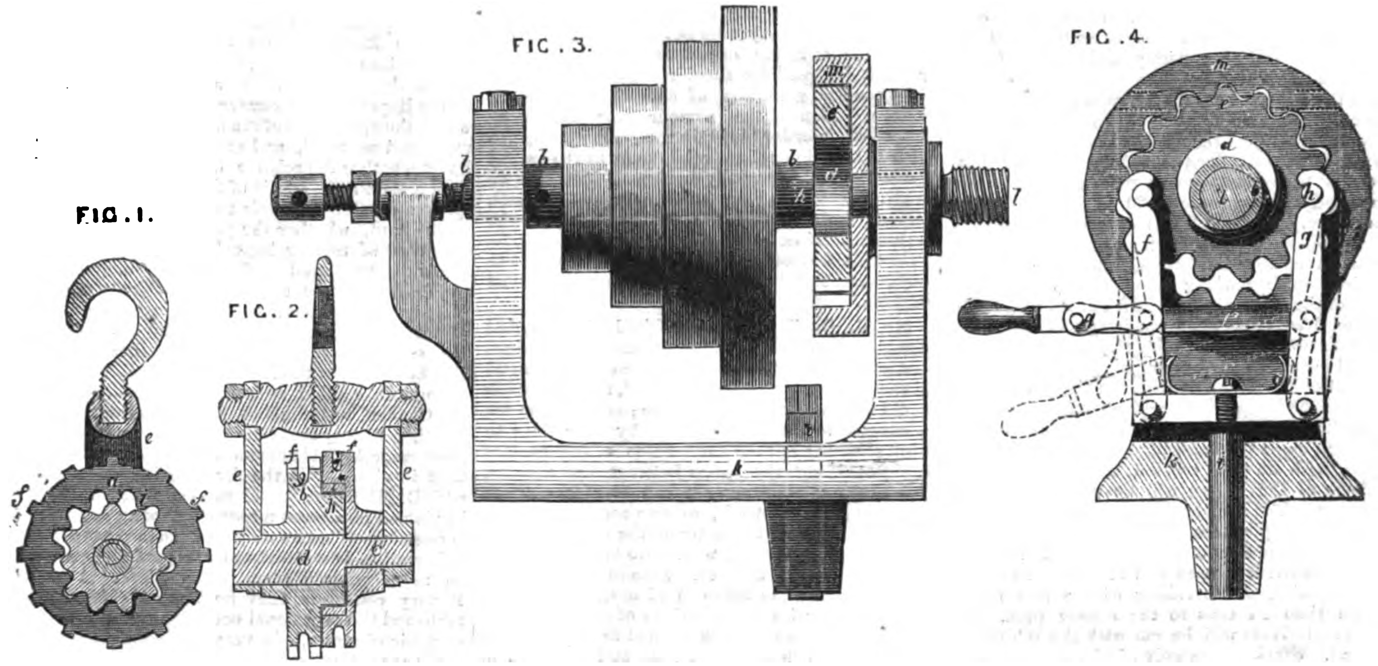


FIG. 1. FIG. 2. FIG. 3. FIG. 4.

the clock, so that the great difficulty hitherto experienced in self-working signals is successfully overcome. The Midland Railway Company, who have erected the one above described, have every reason to be satisfied with the result of the experiment. It is calculated that when adopted double the number of night trains may be safely passed over the line that can be passed over now. There can be little doubt that it will prevent a great number of accidents from trains running into each other; and placed at mouths of tunnels will be of great service. The inventor of this ingenious contrivance is Mr. John King, lace manufacturer, Heanor.

JEWSBURY'S APPARATUS FOR RAISING WEIGHTS.

A PATENT has been obtained by Mr. J. Jewsbury, Kinver, Stafford, for improvements in machines for raising weights, which improvement may also be applied to lathes.

The invention consists in the application to machines for raising weights, and to lathes, of the mechanical arrangements hereinafter described, by which the motion communicated to a shaft or axis is reduced in speed and proportionately increased in force in a simpler manner than by the mechanical arrangements ordinarily employed for that purpose. A crab for raising weights may be constructed as follows:—On an axis turned by a winch or otherwise an excentric is fixed, he excentric carrying a pinion. The pinion is loose on the excentric, the square shoulders or pins on the pinion engage in slots in an oscillating plate or arms, the pinion hence has no rotary motion. The pinion is situated in and engages with an hollow toothed wheel having one or more teeth more than the pinion. On each rotation of the axis carrying the pinion the said pinion is carried round the hollow toothed wheel, and causes the toothed wheel to advance to the extent of one or more teeth. In order still further to increase the power of the machine, the arrangement described may be repeated, that is, the hollow toothed wheel may carry an axis, on the end of which is a second pinion incapable like the first of rotary motion. The second pinion engages with a second hollow toothed wheel, which carries a hollow axis working on the axis of the first hollow toothed wheel. The second toothed wheel advances to the extent of one or more teeth during one rotation of the first toothed wheel. The chain or rope by which the weight is to be lifted may be wound on the hollow axis of the second toothed wheel, or the axis may carry a pinion engaging with a rack.

Fig. 1 represents in transverse section a pulley for raising weights; Fig. 2 is a longitudinal vertical section of the pulley.

The pulley is made in two parts of the same diameter. The part *a* turns on the axis *c*, and the part *b* turns on the eccentric part *d* of the said axis; the said axis *c*, *d*, is fixed in the frame *e* of the pulley. On the periphery of each of the parts *a*, *b*, and near the faces thereof, projections or studs *f* are made in the direction of radii. In the middle of each part and between the studs or projections *f* a groove *g* is made as represented. The chain used with the pulley is temporarily fixed on the parts *a*, *b*, by each alternate link of the chain engaging between the studs or projections *f*, and in the grooves. On the inner face of the part *b* of the pulley a pinion *h* is situated, and in the face of the part *a* a hollow toothed wheel *i* is made, the said hollow toothed wheel *i* being provided with one tooth more than the pinion *h*. An endless chain passes over the parts *a*, *b*, in the following manner:—Commencing with the chain on the near side of the part *a*, the said chain passes over the top of the part *a*, descends on the distant side of the said part *a*, and descending to a distance below the pulley returns forming a loop in which a single pulley is placed, the single pulley being attached to the weight to be raised. The returning chain ascends on the near side of the part *b*, and passing over the top of the same descends on the distant side of the part *b*, and passing downwards below the pulley returns to the near side of the part *a*, the point from which the course of the chain was first described. By pulling one or other side of the hand loop the pulley is made to rotate. The action of the fixed eccentric *d* is to cause the pinion *h* to roll round within the hollow toothed wheel *i*, the teeth of the said pinion engaging during the rolling motion with the teeth of the hollow wheel *i*; but as the wheel *i* has one tooth more than the pinion *h*, the said pinion *h* performs a complete rotation during the time that the hollow toothed wheel *i* is performing a rotation less the length of one tooth. Hence the part *b* of the pulley advances one tooth upon the part *a* during each rotation, and the chain passing over the part *b* is consequently being paid out or drawn in somewhat faster than that part of the chain which passes over the part *a*. The pulley loop is thereby slowly lengthened or shortened, and the single pulley supported in it slowly raised or allowed slowly to descend. The action of the parts of the pulley differs in no essential respect from the action of corresponding parts in the crab already described. In the crab the first motion is given to the axis and eccentric, the pinion on the eccentric being prevented from rotating. In the pulley the first motion is given to the drum or pulley, the eccentric being fixed and the pinion rotating upon it.

Fig. 3 represents a side elevation of a lathe head constructed according to this invention, and fig. 4 is a section of the lathe head. On the hollow shaft *b*, carrying the speed pulley *c*, *c*, is placed an eccentric *d*, which carries the pinion *e*. The pinion is made incapable of rotation by the engagement of the slotted arms or levers *f*, *g*, with the pins *h* on the said pinion *e*. The stem *i*, to the top of which the arms or levers *f*, *g*, are jointed, rises or falls in the bed *k* of the lathe. On the end of the lathe spindle or shaft *l* is a hollow toothed wheel *m*, with which the pinion engages; the hollow toothed wheel having one more tooth than the pinion *e*. By the motion of the pulley shaft *b* the pinion *e* is carried round the hollow toothed wheel *m*, and the lathe shaft *l* made to advance through the distance of one tooth on each rotation of the said pulley shaft *b*, a slow rotary motion is thereby communicated to the said lathe shaft *l*. The lathe shaft *l* and pulley shaft *b* may be coupled together and made to rotate at the same speed by throwing the arms or levers *f*, *g*, out of gear with the pins *h*, and connecting the shafts together by means of the pin *n* passed through them, or in any other convenient way. The holding arms or levers *f*, *g*, are engaged with and disengaged from the pins *h*, *h*, of the pinion *e* in the following manner:—The arms or levers turn on centres and are pressed outwards when at liberty to move by the spring *o* between them. The lever *g* is jointed to the end of the lever *p*, and the lever *f* is jointed to the said lever *p* by means of the link *q*. The lever *p* is on one side and the link *q* on the other side of the arm or lever *f*. When the lever *p* and link *q* are in the positions represented, a pin is passed through them, and the said lever and link fastened together, and the levers *f*, *g*, thereby held in gear with the pins *h*, *h*. By removing the pin and depressing the lever *p* into the position indicated in dotted lines, the levers *f*, *g*, can turn on their centres, and are pressed outwards and disengaged from the pins *h* by the spring. The pinion *e* is then at liberty to rotate with the pulley shaft *b*.

ST. GEORGE'S BRIDGE, CAMBERWELL.

A NEW bridge is about to be built at Camberwell, over the Grand Surrey Canal. It will be erected partly on the site of the present bridge, to which, however, in extent, capacity, and design, it will be greatly superior.

As the approaches, Wells-street and George's-street, are at an angle with each other, it is proposed that the bridge should be placed slightly on the skew, in order that it may be made symmetrical with the approach roads; it is therefore designed with an angle of 83 deg., or 7 deg. on the skew. The width of the roadway, clear of the parapets, will be 40 ft., the pathways 8 ft. wide, paved with tooled York landings, and with an iron curb running along the edges. The span of the bridge will be 23 ft., supported by 15 arched iron ribs. The roadway will be formed of cast-iron cellular plates (Mallet's patent), bolted closely to the upper flanges of the supporting ribs. A handrail will run along the outer sides of the bridge; this will be of iron, wrought in a diagonal pattern, with ornamental bosses. At each angle of the bridge there will be a gas lamp, with an iron twisted stem. The entire surface of the bridge will be covered with asphaltum. The skewbacks, caps, and base mouldings of the pilasters, piers, and coping to the dwarf walls will be of Portland stone. The chief portion of the iron used will be the best wrought Staffordshire, not breaking with a less tensile strain than 24 tons to the square inch. The bolts and rivets will be cut with the Whitworth thread. Stock bricks only will be used throughout the entire work, and picked stocks for facings to the wing walls and abutments, neatly dressed off. The sheet piling, both beneath the bridge and in front of the wing walls, is, after being driven in, to remain permanently, as timber is found to be better than brickwork for barges to strike and roll against in the contracted part of the canal beneath the bridge. As the abutments of the proposed bridge are to be in a line with the present abutments, and will be an extension of the same, it is expected that the old foundations may be made available for the foundations of the new bridge. The works will be carried out so that a clear waterway of 17 ft. is left; and in order to interfere as little as possible with the traffic of the bridge, it will be built in halves —one-half being finished before the second half is commenced.

The estimated cost of the structure is from £1,000 to £1,100. It will be built at the expense of St. George's Vestry, Camberwell. The designer and engineer is Mr. C. Branfield, 10, Bridge-street, Westminster.

RECENT AMERICAN INVENTIONS.

AT a recent meeting of the Franklin Institute, Pennsylvania, Mr. Joseph Clay exhibited his patent air spring trusses. The pads consist of india-rubber hollow semi-spheres, distended with air and covered with cotton fabric; they are mounted upon a piece of leather, having the usual straps and buckles. The ball has sufficient elasticity to perform its office, and at the same time yield to an unusual pressure if brought upon it by accident; thus preventing bruising of the part in contact.

The Committee on Meetings presented the following articles:—A piece of the armour plate of the Whitney Battery, "Keokuk," punched through by a ball during the late attack upon Fort Sumter. It seems to have been struck by a nine-inch round shot, a portion of which was shown at the time. The iron is of good quality, showing fibres at line of rupture. The blow was not perpendicular, judging from the appearance of the piece, which resembles the bowl of a table spoon, with the pointed part rounded off. The back or converse part, where first struck, shows the stretching of the iron before rupture took place. The piece is evidently a part of the inner plate of turret, which is composed thus: first an inner plate of ½ in. thickness, upon which are placed, edgewise, bars of iron 1 in. thick by 4 in. wide, and 1¼ in. apart; the interstices being filled with yellow pine wood; upon these are placed three plates, each ⅞ in. thick. The whole is fastened with bolts of 1¼ in. diameter, passing between the bars, and riveted into countersunk holes. This battery was not intended to resist the action of heavy ordnance at short ranges, but was designed for shoal river service, where the guns are generally of comparatively small calibre. Hence, the armour was placed as described, in order to obtain the greatest strength with least weight of material, so as not to exceed a draft of 8 ft. when fully equipped. There is no doubt she was a very suitable vessel for such service, but entirely unfitted for the part she sustained against Fort Sumter, being nearer to its guns than any of the "Monitor" vessels, whose turrets have about twice the amount of material in them.

Mr. J. C. Garrigues exhibited his patented portable book-case, which is made in sections easily taken apart. The upright ends are hinged in the centre, so that, when folded, their length is equal to the breadth of the case; the shelves are connected to the upright ends by dovetails; to each shelf is attached the portion of the back of the case filling the space between the shelves. The case can be readily taken to pieces when necessary to remove it, as two screws only are used in each end of the top of the case to secure it to the upright ends, which are held in position by the dovetailed shelves. An additional advantage is, that when taken to pieces, by reversing two shelves, with their portions of the back, over each other, boxes can be formed for packing the books and for holding the ends and top piece of the case.

The Committee on Meetings exhibited a number of glass jars of several kinds, sealed by an elastic cap, the patent for which was recently issued to Messrs. Hartell and Letchworth, of that city. This improved cap consists of a rigid plate or disc, of metal or other material, with an annular flanch of gum elastic secured to the edge of the disc. By applying this cap to the mouth of any suitably sized vessel, and turning down the rubber flanch, the latter grasps the vessel with a contractile force sufficiently to hermetically seal the same, and preserve any substance within it from the action of the external air.

Another self-acting device of Mr. Hartell's was shown, as applied to jars containing peaches, pears, &c., which had been enclosed therein for over three years. The fruit was stated to have been placed in the jar as picked from the tree, without any other preparation than to cover it with cold water. To all appearances the articles preserved were as solid as when first picked.

A sketch illustrating an invention of Messrs. Stileman and Ellis, for smelting and melting iron, was shown. This consists in applying to a foundry cupola, or other furnace, a box, between the upper and rear side of which and the base of the cupola, is a pipe, which conducts the metal, as soon as melted, from the cupola to the box, the blast from the cupola passing into the box and out of an opening at the side. The object of the invention is to get rid of the slag and scoria which float on the top of the metal in the box, and are blown out of the opening at the side of the same by the blast, the pure metal being drawn from the tap opening at the bottom of the box. It was stated that by this invention, from old retorts, otherwise worthless, over 75 per cent. of iron might be obtained.

Mr. U. B. Vidal, of Philadelphia city, exhibited several coal oil lamps of his invention, the wick tube of which, above the base of the burner assumes a fan-shape, so that as the wick is raised the upper edge of the same is spread out to nearly double its former width. By this invention the oil carried up by the wick is distributed over so extended a surface that it is entirely consumed, and no portion can remain to clog the wick or run down the outside of the tube, to be evaporated and discharged into the air of the room, as is the case where a large supply of oil is constantly brought to a small burning surface. No chimney is needed with this lamp, which burns without smoke and with a clear flame.

METEOROLOGICAL OBSERVATIONS.

A COPY has been returned to Parliament of a correspondence between the Board of Trade and the Royal Society on the meteorological observations, telegraphy, and forecasts. The Secretary of the Board of Trade wrote in February last to the Royal Society concerning the new features which the operations of the meteorological department had assumed, and expressing an anxiety to know whether the science of meteorology is in such a state as to admit of the permanent reliable system of storm signals and daily weather forecasts; and, whether the progress and useful application of meteorological science will be more efficiently promoted by devoting the money voted by Parliament to the original objects contemplated, viz., the collection, tabulation, and discussion of meteorological phenomena, or by devoting it to the system of telegraphy and weather forecasts. The Secretary of the Royal Society, after the lapse of a month, replied, on behalf of the President and the Council, to the effect that they are assured by Admiral Fitzroy that the original objects for which the meteorological department was formed are still kept in view. "In the forewarning of storms," adds Dr. Sharpey, "much must as yet undoubtedly be viewed in a great measure tentative; but there is one class of cases on which such premonitory information is entitled to be regarded as resting on more assured scientific relations. Admiral Fitzroy considers that he has satisfactorily established the occasional occurence of storms of a cyclonic chracter, of a very limited diameter, not much exceeding perhaps that of the British islands themselves, and orignating in their vicinity. The practice of forewarning is specially suited to such storms. They are characterized by great violence and by frequent and rapid changes in the direction of the wind. The key to their comprehension is supplied by the telegraphic reports which convey to the central office a knowledge of the various simultaneous directions of the wind in different localities; and when once comprehended they are particulary suited for forewarning, inasmuch as, in its general course, the advance of the cyclone is steady in direction and moderate in rate. In connection with this subject the President and Council revert with satisfaction to a reply by Sir John Herschel to the Royal Commision on lights, buoys, and beacons, that 'the most important meteorological information which could be telegraphed would be information first received by telegraph of a cyclone actually in progress at a great distance, and working its way towards the locality. There is no doubt that the progress of a cyclone may be telegraphed, and might secure many a ship from danger, by forewarning.' It is obvious that this remark, which refers to the approach of a distant cyclone, is equally applicable to cyclones originating in or near our islands, the existence of which has been made known by the system of telegraphy which Admiral Fitzory has established. With respect to the 'forecasts of the state of the weather,' which are published in the newspapers, the President and Council learn from Admiral Fitzory that they really occasion no cost to Government, and scarcely fall, therefore, within the questions submitted for reply; moreover, the President and Council have no data whereon to rest a conclusion in regard to the degree of reliance to which these last-named forecasts may be entitled."

FLETCHER'S IMPROVEMENTS IN FORCE-PUMPS.

THE following improvement in force-pumps has been recently patented by Mr. F. Fletcher, of Birmingham.

In constructing or making lift or force pumps for the purposes of raising water out of deep wells, or for supplying cisterns on buildings, or for other purposes, to fix such pumps on solid planks of wood, and then to bolt or fix such plank against a wall or other support, or in cases where such pumps are fixed down in wells, to bolt or fasten them to a solid piece of wood placed either vertically or horizontally, as the case may require, and when a vessel for the

compression of air is used, to attach such vessel externally to what is technically called the chamber of the rising main, and it is usual to make such air vessel of copper.

In this invention the patentee dispenses with the solid plank of wood, and substitutes in the place thereof a hollow box or frame of iron, or other suitable material, on or against which box or frame the cylinder or barrel of the pump is fixed, and if the situation require it, the handle or other apparatus necessary for working the same; this hollow box or frame forms a vessel for the compression of air, by inserting or attaching the delivery pipe thereto, by which arrangement a continuous flow of water from the delivery pipe is obtained while the pump is at work.

MANCHESTER STEAM BOILER ASSOCIATION.

AT the last ordinary monthly meeting of the executive committee of this association, held at the offices, 41, Corporation-street, Manchester, on Tuesday, June 30, 1863, Mr. L. E. Fletcher, chief engineer, presented his monthly report, of which the following is an abstract :—

"During the past month there have been examined 340 engines—2 specially; 528 boilers—10 specially, 12 internally, 104 thoroughly, and 402 externally, in which the following defects have been found :—Fracture, 8 (2 dangerous); corrosion, 34 (3 dangerous); safety-valves out of order, 9; water-gauges ditto, 21; pressure-gauges ditto, 9; feed-apparatus ditto, 2; blow-out apparatus ditto, 35; fusible plugs ditto, 13; furnaces out of shape, 4 (2 dangerous); over-pressure, 2 (both dangerous); blistered plates, 3. Total, 140 (9 dangerous). Boilers without glass water-gauges, 8; without pressure-gauges, 2; without blow-out apparatus, 13; without back pressure-valves, 39.

"EXPLOSIONS.

"No. 10 Explosion.—The fact of this explosion having occurred was stated in last month's report, but no detailed particulars had then been received. It has since been ascertained that the boiler was a plain cylindrical egg-ended one, externally fired, and that the explosion was caused by rents commencing at the seams over the furnace, which has so frequently been found to be the case in this class of boiler, and called attention to in these reports. Two other explosions of a very similar character have happened during this month, particulars of which are given.

"Nine explosions have occurred during the last month, by which 11 persons have been killed and 21 others injured. One of these explosions, which resulted from collapse of the flue, and by which no injury was done either to persons or surrounding property, occurred to a boiler under the inspection of this association; while in the eight remaining cases not one of the boilers was under its care. Details will be found below. The following is the monthly tabular statement :—

"*Tabular Statement of Explosions.*

"From May 23rd, 1863, to June 26th, 1863, inclusive.

"No. 11 explosion occurred to a boiler of a locomotive engine while running with a passenger-train. Between 50 and 60 persons were injured and 4 killed. This result was not occasioned, however, by the explosion only, but principally by the train running off the line. Whether the engine leaving the rails was the cause or the effect of the explosion, is an interesting question, and one now undergoing strict investigation. All the facts likely to prove of value to steam users generally, which may be elicited with regard to this explosion, will be given to the members of the association at the earliest opportunity after the close of the inquiry. The only injuries directly attributable to the explosion are those which happened to the engine-driver and fireman, both of whom were severely scalded, the latter having died in consequence.

"No. 12 explosion, from which 5 persons were killed and 12 others injured, took place at an iron-works. The boiler in question, which was not under the care of this association, was personally examined shortly after the explosion happened, and found to be of cylindrical egg-ended construction, having an internal flue of horse-shoe shape, both the inlet and outlet of which passed through the further end of the boiler, the remainder of the flue being quite independent of the shell, and thus not forming any longitudinal tie from front to back. The boiler was externally fired, the flame first passing underneath the shell, and then entering the flue at one leg of the horse-shoe, and escaping to the chimney through the other. The length of the shell was 28 ft., the diameter 8 ft. 6 in, and the thickness of the plates seven-sixteenths, while the blowing-off pressure was about 40 lb.

"The boiler had rent completely into two parts at the fourth transverse seam from the front end, the larger portion of the shell flying forwards in a straight line from its seat, turning a summersault in its course, and landing in a position quite the reverse of its original one; the egg-end pointing to the brickwork seating, and the open one from it. The smaller portion had flown to a much greater distance than the other, and not, as is usually the case, in a direction immediately opposite, but at right angles to it. A sister boiler working alongside, and connected to the one in question, was moved laterally, sufficiently so to disturb the brickwork seating and break the steam-pipes, though not to unseat it altogether.

"With regard to the cause of the explosion. The boiler was fifteen years old, the plates over the furnace had already been repaired, and it was stated that the seams at that part had been observed to be leaking only a quarter of an hour before the explosion took place; while in addition, the shell was found to be patched in several places, and the plates cracked from the rivet holes to the edge. It is concluded, therefore, on consideration of the circumstances, that the boiler could not have been in good condition, the correctness of which it is thought derives some corroboration from the fact, that the boiler alongside was found at the time of making this examination, to be also leaking at the seams over the furnace, and that considerably, although not under pressure. An examination of the fractures, as well as a consideration of the direction in which the parts had flown, led to the conclusion that the rent had commenced at a longitudinal seam of rivets extending for some two or three plates over the furnace. The rent ran along as far as this longitudinal seam extended, and when met by a plate crossing it, or 'breaking joint,' as it is termed, then developed into a transverse rent, and completely severed the shell in two. It is thought that the fact of this longitudinal rent in the furnace end of the shell, being situated on one side of the centre or 'keel line,' accounts for that portion having been blown laterally, and that the upward direction which it had evidently taken, had caused the summersault of the remaining and larger portion. The explosion therefore is attributed to the imperfect condition of the boiler, and although such defects would not be dangerous in a suitably-constructed, double-flued, or 'Lancashire' boiler, which is always internally fired, they are generally found to be fatal in those boilers which are fired externally; while in the present case the effect was aggravated by the fact of the seams of rivets over the fire being in line, and the diameter of the shell being as much as 8 ft. 6 in.

"No. 13 explosion, by which no one was injured or the surrounding property damaged, occurred to a boiler under the inspection of this association, the particulars of which are as follows.

"The boiler was an upright furnace one, working in connection with two others of similar construction to itself. It was heated by the flames passing off from a furnace employed in preparing heavy forgings; the flames passing through an internal tube in the centre of the boiler, which ran directly from the top to the bottom. The extreme height of this internal flue was 26 ft. 2 in., but it was not of one diameter throughout. In order to admit of a brickwork lining to guard the flue above water line, the upper part was made of a larger diameter than the remainder, and attached to it by a flanged plate which formed a 'set-off' or shelf on which the brickwork rested; again, the lower portion of the tube had a bell-mouth at the bottom, to afford an easy entrance for the flame. The length of the upper part was 11 ft. 4 in., and the diameter 3 ft. 3 in.; the length of the intermediate portion was 10 ft. 4 in., and the diameter 2 ft. 6 in.; while the length of the bell-mouth was 4 ft. 6 in., and the diameter, at the base, 3 ft., the thickness of the plates being three-eighths of an inch throughout, and the blowing-off pressure 55 lb.

"The explosion which did not in any way disturb the original position of the boiler, resulted from collapse of the internal flue tube, the collapse being confined to the intermediate portion just described, which it rent at about the middle of its length.

"A tube of such small dimensions as those just given, namely, only 10 ft. 6 in. in length, and 2 ft. 6 in. in diameter, made of plate three-eighths in thickness, if of good material and workmanship as this one was, would be amply sufficient for a pressure of 55 lb., if working under ordinary circumstances.* This would suggest the conclusion that the water supply had been allowed to run short, but no positive indications of the plates having been over-heated appeared upon examination, though this may, however, have taken place on previous occasions without its being known. On account of the height of these upright furnace boilers, the glass gauges became inaccessible, and the one in question was fitted with two gauge taps only carried down by means of syphon pipes to within reach from the floor. Thus the water could sink below the proper level without affording any external indication, and would consequently pass unknown, should the gauge taps be neglected. This may have happened without any immediate collapse of the tube taking place, although the flue would be materially weakened by it, and rendered liable to give way some time after in consequence. It is impossible to say whether the flue tube was getting out of shape or not, since the boiler had been in such constant work, that no opportunity was afforded the association of making an 'internal' and 'thorough' examination for upwards of three years. This may not, therefore, be an improper time for calling attention to the importance generally of having spare boilers, so that an ample opportunity may be afforded for examination, as well as for cleaning and repair. The boiler was found to be heavily incrusted with hard scale, which must considerably have tended to the overheating and weakening of the flue, to which these vertical boilers are always prone, from the tendency of the ascending steam to cling around the tube and prevent the contact of the water. The inaccessibility of the gauges and fittings of these vertical boilers, on account of their height, is another disadvantage connected with them, and indeed a thoroughly good and safe furnace boiler must still be considered as a desideratum.

"In conclusion, it may be repeated, that this association cannot hold itself responsible for the safe condition of the boilers of those members who do not conform to its rules, and afford it an opportunity of making a 'thorough' examination, every year, of each boiler under inspection. The three years which had been allowed to elapse in the present instance, and during which period the boiler was unceasingly and severely worked—being heated by the intense flames passing from a reverberatory furnace, coupled with the use of very sedimentary water—this, quite precluded the possibility of the association's keeping any check upon the condition of the boiler.

"No. 16 explosion happened at an ironworks, to an externally-fired boiler 40 ft. long, 8 ft. in diameter, made of plates seven-sixteenths of an inch thick. The shell of the boiler gave way immediately over the furnace, the fireman being scalded to death from the stream of hot water issuing from

NOTE.—Since writing the above it has been ascertained that this flue has been re-constructed of plates of precisely the same thickness as the old one, and that on submitting it to the hydraulic test it was found to sustain a pressure of 120 lb. per square inch without yielding in the slightest degree, although carefully gauged. This clearly shows that the flue did not collapse from the weakness of its original construction.

the rent. The boiler had been repaired at this part, by putting on a new plate two months previous to the explosion, and it was at this plate that the rent occurred.

"This boiler, which was not under the charge of this association, was not personally examined on the occurrence of the explosion, but an engineer who inspected it shortly after has kindly furnished the following particulars:—The plate ripped open through the solid metal in two places, the rents being about 15 in. long and 1 in. wide; while the parts surrounding it were a good deal cracked and the seams patched, so that the bottom of the boiler was evidently in a very defective state. The ruptured plate was about seven-sixteenths of an inch thick, and did not appear of very good quality, as if not thoroughly welded in rolling; but the fractures were not, properly speaking, 'blisters,' since the whole thickness of the plate had come down at once. In addition to the inferior character of the plate, the boiler was heavily coated with incrustation, and this had accumulated at the bottom for a depth of 3 in. just over the fracture, and extended for a space of 4 ft. by 2 ft. This mud had hardened so much that the water and steam ploughed but a small hole through it in rushing out. There can be little question that this coating of mud had kept the water away from the plate, and thus led to its becoming overheated, from which it gave way. There was plenty of water in the boiler at the time of the rupture.

"It will be clear that it is scarcely possible for such a cake of sediment to have formed upon the furnace crown of an internally-fired boiler, and also that an efficient blowing-out apparatus would have prevented the accumulation in a great measure, if not altogether, and thus that the explosion was due to the dangerous character common to all externally-fired boilers, coupled in this case with neglect.

"L. E. Fletcher, Chief Engineer.
"Offices—41, Corporation-street, Manchester."

Note.—Since the above report was in print, another explosion has happened, from which nine persons were killed and five others injured. The fragments of the exploded boiler have been personally examined, and particulars will be given in the next monthly report. The boiler in question was not under the inspection of this association.

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the Mechanics' Magazine at the rate of 6d. per line, or 5½d per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

All communications should be addressed to the Editor, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

Received.—R. T., W. A., G. C., J. C. W., H. C. M.

W. K. (Canterbury).—We are not aware that any such demonstration has ever been published. We earnestly recommend our correspondent to refer to our abstracts of specifications, where he will find an almost weekly record of inventions which are intended to accomplish such a purpose, he will find the ominous "patent abandoned" follows as a matter of course. It is utterly impossible to create force, and we cannot do better than recommend "W. K." to put by his demonstration for a month, think no more of it for that time, and then look it over again. He will be sure to detect his error. We have answered this correspondent at some length, because the sum annually wasted in the pursuit of that myth, the perpetual motion, is positively lamentable.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—In order to protect our new wood wheels from damp, we have up to the present time, when finished out of the hands of the maker, given them one coat of the best red paint, then filled up all screw heads with putty when dry; then given a second coat of red paint, and when dry sand-papered it all over, then given a coat of naptha varnish, and it is then ready for use. True, we like red paint better than any other, both for its body and colour, but the process is too long in having to wait of the two coats getting dry. What we want to know is, first—Can you give us any receipt to paint or varnish new wood wheels so as to protect them entirely from all damp; and, second, for them to have a very smooth surface, so as to draw out of the sand smooth, free, and easy. Of course, the freer they come out of the sand the smoother the casting.—Engineer.

Why paint your wooden patterns at all? We would recommend three or four coats of varnish made of the best shellac, dissolved in purified naptha; three coats of this should be dry in 12 hours; it is beautifully smooth, and will effectually keep out damp. Can our correspondents suggest something better?—[Ed. M. M.]

Correspondence.

TWIN SCREW STEAMERS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—I have observed with some interest the controversy which has recently been waged through your columns, and that of other scientific journals, in reference to the supposed originators of the proposition for the application of twin screws to steamships. It is not my intention to take part in that controversy, but justice demands that I should state a fact or two in reference to the subject of it.

In the winter of 1848-9, Mr. Joseph Apsey, a gentleman who at that time was in business for himself, in a rather humble way, as an engineer and machinist, near the Blackfriars-road, called upon me. He at the same time exhibited drawings which he had made of a steam-ship in which a screw was shown under each quarter. A model of the the screws in brass was also exhibited by him on the same occasion, and this had peculiar, and as I thought, excellent features about it. The screws were to be driven, he said, by separate engines in order to facilitate turning and steering the ship. Mr. Apsey persistently advocated his plans, and solicited my assistance in realising them. His wish was to fit up a boat with two screws and separate engines, and run her on the Thames. Like many other clever inventors, Mr. Apsey lacked the requisite funds for carrying out his designs; but I know he revealed them to many engineers besides myself, and who probably will corroborate what I assert.

It was simply want of money that prevented the twin screw system of Mr. Apsey from being practically tested so long back as the year 1849, and it seems to me that this fact ought to be made known. What has become of its author now I know not, and I am no advocate of the scheme. My own faith lies rather in the direction of the recently patented plan of Mr. Vaile for marine propulsion—that of feathering-floated chain-propellers. It is solely with a desire to "render unto Cæsar the things that are Cæsar's" that I have put forward Mr. Apsey's claims as the real originator of twin screws and separate engines.

I am, Sir, yours, &c.,
Joseph Newton.

Royal Mint, July 1, 1863.

Miscellanea.

The French Government have ordered a submarine cable from Messrs. Siemens and Co., to be laid from Oran, in Algeria, to Carthagena, in Spain. This is to supply the service formerly effected by the deep-sea cable from France to Algiers, which broke down at the end of last year, and has since been abandoned, from the impossibility of repairing its defects in deep water.

The iron-cased frigate "Solferino" now lies ready for sea in Cherbourg. She is described as a ship of war of most formidable proportions, armed with a spur of a very strange form. The spur is so arranged that it becomes part of the entire vessel, and any shock it has to support will be felt throughout the ship. The shaft of the screw is, by a very ingenious mechanical contrivance, protected from any injury in consequence of the shock caused by the spur. The shaft may recede in such case without causing any inconvenience.

A remarkable work has been accomplished at Worcester, Mass. The chimney-stack at the iron-works of Nathan Washburn, which is 100 ft. high, having in it 60,000 bricks and weighing 170 tons, was moved a distance of 150 ft., and turned partly round, without the slightest accident.

The introduction of machine-made bags dates subsequent to the Exhibition of 1851, and already all branches of trade are using them. The manufacture of this article is taking up a large share of the papermakers' attention. The great consumption of grey and brown paper is falling into the hands of manufacturers of machine paper bags. One of the large London works employed in making them, turns out 130,000 per day.

A successful experiment was made lately at Havre with a gun invented by Count d'Haudetot, for throwing a rope from the shore to a ship in distress. The rope was carried a distance of 240 yards by a shot weighing 10 lb. The inventor says that the greatest distance to which a rope has been thrown by a similar instrument is 200 yards, and that the shot used weighed 20 lb.

From information received from Quebec, we learn that the mineral wealth of Canada is slowly but surely and most satisfactorily becoming developed. It is something less than six years since the copper regions of Lower Canada first attracted attention, and we now find them filled with mining enterprize, drawn by the rich promise from Europe and the States, bringing abundant capital and giving employment to hundreds. The Acton mine, in the county of Bagot, was the first to which much attention was directed, and the success of the operations in regard to production and money value are supposed to be without parallel. Within three years after it was opened 490,000 dols. worth of ore had been obtained, and between 500 and 600 hands were employed in its working. The Harvey Hill Mines, in the county of Leeds, a large interest in which was held by citizens of Quebec, is, as we learn, a still more valuable property than that of Acton. These mines have been disposed of within the last few days to Boston capitalists for the sum of £50,000 sterling. 322 tons of this ore from the Harvey Hill Mine, sent to England, give an average of 38 per cent. This is a much higher percentage than is generally obtained, but we are informed that much of the ore raised from this mine is as high as 50 per cent.

Mr. Archibald Sturrock, the engineer of the Great Northern Railway Company, has just patented an invention, by which the power of locomotive engines is greatly increased, and at comparatively little cost. The tender is converted into an auxiliary power. Cylinders are placed underneath, and are supplied with steam by the boiler of the locomotive. There is no necessity for using this additional power except at pleasure, and on heavy gradients; but, by its aid, one-third more tonnage may be attached to a train than can be taken by the engines now running. With the apparatus in the tender, an engine, without any increase of heating surface, has been for a fortnight, and is now daily working over the Great Northern Railway from Doncaster to Peterborough, and dragging forty loaded coal trucks, when the most powerful ordinary engine can only take thirty.

The *Rangoon Gazette*, in speaking of a land telegraph from Rangoon to China, says:—Captain Sprye and his son propose to carry on the telegraph wires, by land, from Shway-Gyeen to Hong Kong, through Kiang-Tung, Kiang-Hung, Esmok, and the principal cities and towns of the Chu-Kiang, or Pearl River Valley; the estimated distance being 1,100 miles only. This line, when completed, would enable Hong Kong to correspond with Galle in ten hours; in less time, in fact, than it now takes the steamer to coal at either place. And thus the governments and merchants of India and England would receive seventeen days' later news from China than they now get; while the Hong Kong public would actually receive the English summary of intelligence before the departure of the China steamer with it from Galle. We have remarked, that from Shway-Gyeen to Hong Kong is a portion only of the Messrs. Sprye's project. A second division is to carry on the wires from that port, through Amoy, Foo-choo-foo, Ningpoo, and the principal cities and towns along the coast of China to Shanghai. The estimated distance of this extension is 850 miles, and the gain in time between Galle and Shanghai would be increased to 22 days. On the completion of this second division there will be a hopeful prospect of still further extending the line fron Shanghai to Pekin, throw Hankow, and Tien-tsin; and ultimately when modern invention shall perfect telegraphic cables, from Shanghai to Japan. A telegraph eastward, from Calcutta, confined to the limits of British Burman, can never pay, and will never achieve anything of real importance, politically or commercially; whilst by extending its wire onward, as proposed, to the opposite limits of China—the most populous and civilized country of the East—it must carry with it there our country's influence, be a powerful assistant to our own Home Government in its intercourse with the Governments of China and Japan, of daily service to the merchant communities of of England, India, and China, and would prove, we are surely not too sanguine in predicting commercially, a great success.

A meeting of the Geologists' Association will be held on Monday next, at 7 p.m., when E. Charlesworth, Esq., F.G.S., will read a Paper on "Ammonites," and Dr. Richardson will read a description of the Excursion to Dudley. The Paper on Ammonites will be illustrated by a fine series of fossils, to be exhibited by J. F. Collingwood, Esq., F.G.S.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c., 3188, 3195, 3197, 3207, 3220, 3224.
BOILERS AND FURNACES, 3181, 3182, 3194, 3196.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 3191, 3193, 3202, 3209, 3214, 3233.
SHIPS AND BOATS, including their fittings, 3231, 3235.
CULTIVATION OF THE SOIL, including agricultural implements and machines, 3201, 3212, 3216.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 3192.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 3183, 3186, 3190, 3199, 3217, 3223, 3229.
BUILDINGS AND BUILDING MATERIALS, 3230, 3239.

3181. D. and D. AULD, jun. *Improvements in working furnaces and steam boilers, and in apparatus connected therewith.* Dated November 27, 1862.

This invention relates to the arrangement and construction of apparatus for regulating the supply of air to the furnaces of steam boilers; also to self-acting apparatus for supplying water to the boiler. The self-acting apparatus for supplying air to the furnace consists, under one modification, of a sliding panel arranged at the front of the furnace door, the back part of which is formed with openings similar to the arrangement of a Venetian blind. The sliding panel is connected to a chain, which is carried over a pulley arranged on the upper part of the boiler, and is attached to a bell crank or other suitable lever, by which it is connected to one of Auld's self-acting dampers, or other similar and suitable apparatus. In lieu of the arrangement of a sliding panel, a throttle or other suitable valve may be used instead, where such modification is found more convenient. When the pressure of the steam falls, the damper apparatus is brought into operation, and this being in connection with the sliding panel or other valve, is thereby raised so as to allow a larger supply of air to pass through the fuel, and thus increase the rate of combustion, as well as the generation of the steam. On the other hand, if the steam is generated too rapidly, the self-acting apparatus causes the damper and sliding panel, or its equivalent arrangement, to be lowered, and so check the combustion of the fuel. *Patent completed.*

3182. J. L. LINTON. *Improvements in the means of generating steam, and in the apparatus to be employed therein.* (A communication.) Dated November 27, 1862.

This invention consists—1, in the application of ignitable fluids, such as petroleum and other mineral oils or hydro-carbons, to the purpose of generating steam for boilers; and 2, in the apparatus to be employed in the combustion and utilization of the said fluids, in order to obtain and apply the resulting heat to such steam boilers, the object being to mix air with the vapours of the oil or ignitable fluid for the purpose of thoroughly consuming the same. *Patent abandoned.*

3183. D. VERKAMP and C. F. A. VAN TRIGT. *Improvements in the treatment of old manufactured fabrics in order to obtain useful fibrous products therefrom.* Dated November 27, 1862.

An extension of time for filing the final specification of this invention having been petitioned for, the documents relating to the invention cannot at present be seen.

3184. W. CLARK. *Improvements in the preservation of animal and vegetable substances.* (A communication.) Dated November 27, 1862.

This invention consists in the employment of a coating consisting either of vegetable tar heated to a temperature of 160 deg. to 180 deg. Fahr., or of varnish obtained from hydro-carburets. The patentee claims—the application of a coating to varnish substances previously prepared in a toxical or antiseptic solution, as described, in order to prevent the dissipation of the preservative matter when the said substances are to be exposed to the action of water. *Patent completed.*

3185. W. CLARK. *Improvements in gas burners.* (A communication.) Dated November 27, 1862.

This invention consists in regulating the amount of air supplied to the burner exactly to that which is necessary for proper combustion. This the inventor effects by means of taps, valves, or other similar apparatus, self-acting or otherwise, the burner being enclosed in a chamber to which the admission of air is regulated, as described. *Patent abandoned.*

3186. J. CARBONELL. *Improvements in preparing, manufacturing, and washing the paper pulp derived from the esparto plant.* Dated November 28, 1862.

This invention consists, mainly, in submitting the esparto plant to sundry washings and boilings in water containing salt of soda, quick lime, chloride of lime, sulphuric acid, and other chemicals. Special machinery is employed. *Patent abandoned.*

3187. W. A. WADDINGTON. *Improvements in machinery for cutting wood.* Dated November 28, 1862.

In carrying out this invention the wood to be cut is clamped or fixed on the sliding part of the surface of a bench. This sliding part receives motion by means of a horizontal shaft on which there is a pinion which takes into a rack on the under side of the sliding part of the bench. Motion is communicated to this horizontal shaft or axis by a screw or worm on an upright shaft, which takes into and drives a screw or worm wheel on the horizontal shaft. On the screw or worm shaft is a pulley or drum, which receives motion by a band or strap, driven by a pulley or drum on the driving shaft. Two upright shafts are used, each of which carries a rotating cutter, which, by preference, consists of three cutting blades of the shape or contour of the intended front for a pianoforte or other similar work. Each of the right cutter shafts is driven by a strap on a drum or pulley on the driving shaft. By this arrangement the wood to be cut, as it is moved by the sliding part of the bench, is presented progressively to the cutting blades of the rotating cutter, which is fixed on the upper end of each upright shaft, and above the surface of the top of the bench. *Patent abandoned.*

3188. J. T. CAIRD. *Improvements in steam engines.* Dated November 29, 1862.

The patentee claims—1, the application and use of expansion or cut-off valves, arranged on the steam belt, and by preference between the steam trunnions and ordinary slide valves of oscillating steam engines, as described in the specification, and shown in the drawings; 2, the systems or modes of arranging and constructing the gearing for actuating the expansion, or the slide valves of oscillating steam engines, for regulating the extent of motion of the same, so as to produce any required amount of expansion of the steam, as described in the specification and represented in the drawings. *Patent completed.*

3189. J. H. JOHNSON. *An apparatus for indicating the pressure of electric conductors in foreign bodies.* (A communication.) Dated November 28, 1862.

This peculiar apparatus consists, essentially, of a hollow sounding or testing rod, within which is placed, so as to be free to move to and fro, another rod, which, in all cases, is insulated completely from the outer tube or sounding rod. One pole of a battery is connected with the outer tube, and the other pole with the inner rod, and with either of these parts there is also connected, so as to be in the electric circuit, a small electric alarm bell or signal and galvanometer. The internal rod may either remain fixed to the tube, so that its lower extremity is always flush with the end of the tube, or it may, when not in action, be retained and held up away from the lower end of the tube by means of a spring catch or other convenient contrivance. If this apparatus be now inserted into a boring, pushed into sand, or submerged, the instant the extremity of the tube comes in contact with or strikes a resisting body, the resistance occasioned will effect the release of the inner rod, and cause it to descend until its extremity also comes in contact with the same body, and if such body be metallic or conductive of electricity, a circuit will instantly be established between the tube and the inner rod, through the contact therewith of the conductive medium, and a current of electricity will pass through the apparatus, ringing the bell, and indicating its presence on the galvanometer. *Patent completed.*

3190. F. BOECKE. *Improvements in sewing or uniting fabrics, and in the machinery or apparatus employed therein.* Dated November 28, 1862.

This invention relates to certain improvements upon what are commonly known as the Wheeler and Wilson and the British sewing machines, but they are also applicable to other sewing machines of the same character, or where the driving shaft is similarly placed. According to this invention, it is proposed to construct the bobbin or under thread case or shuttle of the Wheeler and Wilson, or the British sewing machine, with a raised conical or rounded boss or projection in the centre, on that side next which the needle works, a corresponding recess being made in the back of the hook when adapted to the Wheeler and Wilson machine to receive the projection on the inner side of the bobbin thread case or shuttle. By the aid of a thread case or shuttle fitted or formed with this projection a twisted chain stitch, having a second thread passing through the loops, may be produced in the Wheeler and Wilson, or in the British sewing machine, or in any other working on the same principle; or, if desired, the second or under thread may be dispensed with, in which case the machine will produce the twisted chain stitch from a single thread. The object of the projection in the side of the bobbin thread case or shuttle is to hold each one side of the loop of the needle thread until the point of the needle has passed down in front of it, so that, on the thread slipping over the projection, the loop will be round the needle, and, consequently, round the thread carried by the needle, thus forming the chain stitch. The operation is precisely the same when a second thread is used. *Patent completed.*

3191. J. CRESWELL and E. T. GREVES. *Improvements in the construction of hearses and funeral carriages.* Dated November 29, 1862.

In carrying out this invention the patentees construct a hearse with several compartments, the number found convenient being about twelve. The hearse is thus arranged:—In the fore part of the carriage over the front wheels are four compartments, two, one over the other, on either side; these are closed from the side of the hearse by suitable flap doors or drapery. On the rear part of the carriage are six similar compartments, so that the hearse is of a length to contain two coffins laid end to end; the compartments in the rear part of the carriage are closed at the back. By cranking the rear axle of the carriage, space is obtained for two more compartments hung from the body of the rear part of the carriage, thus making one hearse to contain twelve corpses in separate compartments. The improvements in funeral carriages consist in adapting one carriage to the conveyance of several parties of mourners separately; and with this view the patentees propose to construct a long carriage similar to an omnibus, but divided inside into two or more compartments, which can be closed by sliding doors or curtains, or in any other similar manner. *Patent completed.*

3192. S. J. BROWNING. *Improvements in machines to be employed in brewing.* Dated November 28, 1862.

This invention relates—1, to a machine for mashing and extracting; and, 2, to a combined refrigerating and cooling machine. The machine for mashing and extracting consists of a containing tun or vessel, in which the patentee fits an agitator furnished with inclined vertical and central horizontal blades, set spirally, which, when rotated, have a centripetal effect; that is, they drive the "goods" towards the centre. In order to obtain the greatest amount of extract from the "goods," he carries a pipe along the top, down the sides, and along the bottom of the agitator frame, and causes this pipe to communicate with inlet and outlet tubes. The pipe travels with the agitator, and thus maintains, or assists in maintaining, an even temperature throughout the tun. *Patent completed.*

3193. W. CLARK. *Improvements in the permanent way of railways.* (A communication.) Dated November 28, 1862.

The patentee claims—1, forming separate and independent sleepers of bridge or gutter iron, and also the application of double T-iron, with broad flanges, having suitable seats provided therein, for carrying double-headed rails, all as described; 2, the application of similar sleepers, connected together by means of ties underneath the sleepers, so as to afford a continuous firm bed for the same, all as described. 3, the application of undulated longitudinal plates, connected either by means of bridge iron of the same depth as the undulations of the plates, or by means of cross ties, as described; and also the various improvements in permanent way described. *Patent completed.*

3194. W. BUTLER and J. H. MUGFORD. *Improvements in spur-supporting rings for fixing plates, dishes, and other like articles in glost ovens.* Dated November 28, 1862.

This invention consists—1, in making the spur-supporting rings in the form of a circular ring, and in one piece, with three or more legs, which form admits of the plates or other earthenware articles being placed in closer proximity to the article underneath, and thus effecting a very considerable saving of room in the ovens; 2, in supporting the plates, saucers, or other articles on small moveable "points" or pyramidal spur pieces, placed upon or otherwise inserted in small eyelet holes or grooves, made for this purpose in the circular rim, and so as to be renewable at pleasure. *Patent completed.*

3195. J. F. DELANY and J. C. R. OKES. *Improvements in double cylinder expansive steam engines.* Dated November 28, 1862.

For the purposes of this invention, the slide valve of the high pressure cylinder of a double cylinder expansive steam engine is made with "lap" at each end, whilst the slide valve of the low pressure cylinder is made with no lap, or with as little lap as may be. These slide valves are to be worked or moved in any suitable manner, but so that the slide valve with the lap may precede the movement of the slide valve of the low pressure cylinder. *Patent completed.*

3196. J. ADAMS and W. C. WHITE. *Improvements in apparatus for boiling and evaporating.* Dated November 28, 1862.

This invention consists in certain improvements in apparatus suitable for the boiling and evaporating of solutions and liquids generally, and applicable to the manufacture of sugar preserves, sweetmeats, to preparations from drugs and chemicals, and many other useful purposes. The patentees construct a copper or other metal pan with a false bottom, and support the same by means of trunnions set in bearings on standards, and apply and fix to the interior of the pan a circular, spiral, or other form of tube, according to the shape of the pan or vessel. This tube is perforated with a number of small holes, and is supplied with steam from a boiler, or with hot air, which enters at one of the trunnions formed hollow for the purpose. The steam or hot air rushes into the hollow chamber of the pan by means of the hose-like apertures, and heats it to the required temperature for boiling or evaporating, according to the liquid, syrup, or solution to be treated. From the bottom and interior of the hollow pan a pipe ascends to the opposite trunnion, in order that the water of condensation may be forced up the pipe by the pressure of the steam, and driven out of the pan. *Patent completed.*

3197. A. DUDGEON. *Improvements in packing for various parts of steam and other engines and machinery.* Dated November 28, 1862.

This invention consists in plaiting cotton or other vegetable fibre into the form of a gasket, or otherwise twisting it, so as to form a rope. The patentee makes the rope with or without a core of elastic or non-elastic material. He either treats the vegetable fibre, or the manufactured gasket or rope, by steeping it in a vessel or vat containing a solution of silicate of potash, silicate of soda, stannate of soda, arseniate of soda, or of other chemical substances or compounds possessing similar properties, for enabling the material treated therewith to resist the action of great heat. The chemically treated gasket or rope he next steeps in a melted solution of paraffine, or of the preparations made therefrom, together with black lead, French chalk, or with an amalgam of mercury and tin, or any other amalgam possessing lubricating properties. When the gasket or rope has absorbed as much as it will take up of the solution next above described, he, in order to thoroughly incorporate the said materials with the rope or gasket, passes the rope

or gasket through or in between rollers, rotated by any convenient means, and the faces of these rollers are so constructed that they press or mould the prepared gasket or rope into the precise form which may be desired. *Patent completed.*

3198. W. E. GEDGE. *Improvements in the construction of clocks or timekeepers.* (A communication.) Dated November 29, 1862.

This invention consists—1, in the establishment of the striking work in the centre of the cage; 2, the suppression wheel, of the first wheel of the movement; 3, in replacing this the spindle, the pulley, the clockwork, and the weights, by a watch spring (No. 37) winding up three times in the hour by the action of the striking work; 4, in the suppression of the second wheel of the movement by means of a toothed gearing carried by the first wheel of the dialwork; 5, in setting the motor by the large hand; 6, in the suppression of the main detent, replaced by an extremely accurate and certain piece; 7, in the establishment of the species of anchor escapement forming part of this invention; 8, in the establishment of a stop-piece, forming the movement, to travel conjointly with the striking work; 9, in the supression of the key, by a counterweight; 10, in the establishment of a spring with four branches and reservoir. *Patent completed.*

3199. T. BLACKBURN and M. KNOWLES. *Improvements in looms for weaving.* Dated November 29, 1862.

Instead of the ordinary tappet for shedding in looms, the inventors, according to this invention, place upon the crank shaft a tappet so constructed as to lift only once for every two revolutions of the crank shaft, and by connecting a lever therefrom to the heald roller boss, or to any other fixing upon the heald roller, by means of straps or other suitable means, they raise or depress the healds, and thereby obtain the shed; and at the same time, by placing another lever in a vertical position, they are enabled to regulate a fixing on the picking stick shaft, so that a boss or projection fixed upon the fly-wheel would, in working, come in contact with the said fixing on the picking stick shaft alternately at the opposite side of the loom, thereby giving motion to the picking stick and throwing or picking the shuttle. Instead of the ordinary fixings for tappets and wheels for working, so as to keep proper time, they make a boss, on the face of which they cut teeth at uniform pitches, and by casting corresponding teeth on the boss of the wheels or tappets, and then attaching such bosses firmly on the shaft, they can, by means of a nut, force the wheels or tappets against such fixed boss at any given angle, regulating thereby the time of shedding and picking. *Patent abandoned.*

3200. F. G. TAYLOR. *Improvements in washing machines.* Dated November 29, 1862.

In carrying out this invention, the patentee employs a box or vessel having a part of its bottom made a segment of a circle, and another part an inclined plane, with a corrugated washing plate or board attached to it. He places in the interior of the box a squeezer or rubber, consisting of a number of horizontal slabs or boards, separated from each other at short intervals, and connected to arms or levers working in suitable bearings. To the sides of the box he hinges a board having vertical ribs in front, and acted upon by springs at the back, so that it shall have a re-acting action after pressure has been exerted upon it. The horizontal boards of the squeezer or rubber and the vertical ribs of the hinged board are either plain or covered with india rubber, as may be required, and the arms or levers for working the squeezer are either moved to and fro directly by hand or by means of eccentrics or cranks on a revolving shaft driven by hand or power. The box or vessel is supplied with water or a washing liquid, and the clothes or fabrics to be washed are placed against the hinged board, and the squeezer or rubber is repeatedly pressed against them, causing the position of the clothes to be continually changed. Above the hinged board there is a top board so inclined that the water or liquor, when it is pressed out of the fabrics, is returned upon them with increased force, without any additional labour, thus producing as nearly as possible the effect of rubbing and changing by human hands. *Patent completed.*

3201. J. CROMPTON. *Improvements in machinery or apparatus for ploughing, harrowing, clearing, and drilling land.* Dated November 29, 1862.

This invention consists of an improved arrangement and combination of a portable steam engine, with ploughs, scarifers, harrows, and other agricultural machines, and also revolving cutters, driving pulleys, and a crane, the details of which we cannot give space to here. *Patent abandoned.*

3202. T. LLOYD. *Improvements in, and applicable to, the wheels of vehicles.* Dated November 29, 1862.

This invention relates to improvements in the wheels of vehicles with the view to render them suitable for use on both railways or tramways and common roads; and also to the application of parts of such improvements to wheels now in use, or others similar thereto, in order to render them suitable for the same purposes or uses, the chief object of the invention being the production of a simple self-acting arrangement of parts, unlikely to get out of order, capable of thoroughly guiding the wheels of the omnibus, or other carriage, when bearing on the rails or trams, and offering a minimum of resistance when used on common roads, and when moving or passing on to or off from the rails or trams. *Patent abandoned.*

3203. T. EVANS. *Improvements in antigrophilos.* Dated November 29, 1862.

This invention consists in forming an antigrophilo, or eknemedia, of two parts, in such a manner that the upper part may be removed from the lower part, which latter can then be used as a gaiter, legging, or splatterdash. *Patent completed.*

3204. W. CLARK. *An improved machine for cutting corks and other stoppers.* (A communication.) Dated November 29, 1862.

The object of this invention is to obtain a machine for cutting corks for stoppers, which will perform the work rapidly and be capable of being adjusted readily, so as to cut the corks of cylindrical or taper form, as may be desired, and of any required degree of taper and size. The invention has also for its object a simple and automatically operating means for clamping and holding the corks to be cut. To these ends the invention consists in the employment or use of a tilting frame or arms provided with one or more arbors, which are rotated or thrown in and out of gear by the tilting movement of the frame, the latter being operated by the cutter shaft, and the arbor or arbors provided with clamps or holders, which are also operated by the tilting of the arbor frame, the above parts being also used in connection with feeders, also self operating, and a rotating circular cutter, all arranged. *Patent completed.*

3205. F. VACHER. *Improvements in ornamenting playing cards.* Dated November 29, 1862.

In carrying out this invention, the patentee proposes to take the packs of cards, after they have been completed by the ordinary processes of manufacture, to place them in a suitable press, and to scrape their edges in order to produce a smooth surface thereon, after which the edges are to be sized, and then glazed, or treated with albumen, and covered with gold or silver leaf, after which the surfaces are to be burnished. He also proposes to apply bronzes in powder or leaf of any desired colour to the edges of the packs after the requisite adhesive preparation. The edges may then be burnished. The bronze may be of a variegated colour or mixture. He also proposes to ornament the edges of the cards by colouring them in order to present an uniform body colour, or a variegated or sprinkled surface, which may then be burnished in the ordinary way. *Patent abandoned.*

3206. J. C. ROBERTSON and W. C. WHITE. *An improved tap or cock.* Dated November 29, 1862.

This invention consists of an improved tap or cock, the object of which is to render it self-closing, in order to prevent the escape or waste of the contents of a cask or barrel, or of water from ordinary household taps, or of any fluid through accidental circumstances, or negligence in leaving the tap or cock open or turned on. The patentees enlarge the upper part of the plug holder of the tap, so as to form a circular chamber therein, in which they place a helical spring, either of flat steel similar to a watch spring, or of round wire, and fix the same by means of a stop or stud. The plug of the tap is furnished with a similar stop or stud taking into a slot cut in the other end of the helical spring, or in the case of round wire taking into a ring formed by the twining over the end of the wire. A moveable cap encloses the top of the chamber, and the under surface of this cap has fixed or soldered thereto a small projection corresponding with a stud on the top of the enlarged surface of the plug contained in the chamber. *Patent completed.*

3207. H. MOULE. *Improvements in locomotive engines, and in apparatus for generating steam for steam engines.* Dated November 29, 1862.

In constructing a locomotive or other engine according to this invention, the patentee makes the fire box and ash pit of the engine of suitable dimensions. The bottom and sides of the ash pit are closed water-tight, in order to its containing water below the fire bars. At the sides of the ash pit openings are formed for the admission of air to the fire. Over these openings slides or covers are used, in order to regulate the admission of air; and when desired to shut off the supply of air altogether, a steam pipe is applied between the ash pit and the steam boiler, in order that steam may be admitted to the ash pit. On the steam pipe is a cock or valve by which the supply of steam to the ash pit may be regulated or shut off. Into the ash pit a mixture of oil or oily and fatty matters mixed with powdered coal is to be introduced, and a supply of water is to be constantly kept up in the ash pit, so as to touch the fire bars, or to come as near thereto as may be. On the fire bars alternate layers of coal or coke and chalk, limestone or lime, are to be placed, sufficient to fill the fire box to the required height. Or the fuel and chalk limestone or lime may be mixed before introducing them into the fire box. The fire is to be lighted, air being admitted freely at the openings at the sides of the fire box or ash pit. When the fire is well ignited, steam may be admitted into the ash pit from the steam boiler, and the admission of air may generally be reduced. *Patent completed.*

3208. D. SUTTON. *Improvements in apparatus for washing linen and other fabrics and garments.* Dated November 29, 1862.

For the purposes of this invention a vessel is used, by preference of a rectangular form, with a flat bottom suitably constructed to admit of the vessel being rocked to and fro thereon. The top of the vessel is closed with a cover, which has an opening in the middle. On the four sides and bottom are fixed numerous semi-spherical projections; transversely across the upper part of the vessel is an axis, either plain or threaded towards the ends—so as to obtain a to-and-fro motion, as well as a rotating one—on which are four or other suitable number of floats or paddles, and there are also two other axes transversely across the vessel, having each four or other suitable number of floats or blades. These axes are preferred to be fixed near the bottom, and transversely of the vessel is fixed a half round or other shaped bar, with numerous semi-spherical projections fixed on the upper rounded surface. The lower inner angles of the vessel are filled, and have similar projections fixed thereon to those above-mentioned. At the upper part and at one end of the vessel, there are fixed two uprights, which are connected together at their upper ends by a bar which is used as a handle to communicate a rocking motion to the vessel. *Patent completed.*

3209. J. ANDERSON. *Improvements in the manufactures of the tyres of railway wheels, and rails, switches, and crossings of railways.* Dated November 29, 1862.

This invention consists in heating the tyres of railway wheels, and also the rails, switches, and crossings of railways when made of steel or carbonized iron, to a bright red heat, and quenching or cooling the same by immersion in oil. *Patent completed.*

3210. R. K. PENSON. *Improvements in apparatus used for warming railway carriages.* (A communication.) Dated November 29, 1862.

For the purposes of this invention, a warmer is placed between the seats, and in a position to come under the feet of the passengers. It is preferred that this warmer should consist of a flat tubular chamber, but the section and form of the warmer may be varied. A portion of the funnel or chimney of the locomotive engine is partitioned off so as to produce a compartment open at the bottom to intercept part of the steam from the steam cylinders. This compartment has a door or cover at the upper part, which, when open, allows all the steam to rise up through the funnel or chimney into the open air, without being conducted into the warming apparatus fixed in the passenger carriages. A steam pipe is connected to this compartment in the chimney or funnel, by which the intercepted portion of the steam is conducted to the warming apparatus in the passenger carriages. *Patent abandoned.*

3211. M. HENRY. *Improvements in the manufacture of leather.* (A communication.) Dated November 29, 1862.

This invention relates to a mode of treating tanned skins and hides before they are curried, and it has for its object to render them thicker, stronger, and more durable, and to improve their quality. For this purpose the tanned skins or hides are treated with chondrine, glutine, or other proteic and gelatinous matters, or with substances congeneric or kindred thereto, employed by preference in combination with neutral salts, or with a metallic oxide of antimony, cobalt, cadmium, bismuth, tin, nickel, lead, or zinc. An agent or composition for the purposes of this invention is manufactured by combining gelatine, glycerine, and animal albumen with a neutral salt, or with one of the oxides before mentioned. *Patent completed.*

3212. H. L. EMERY. *Improvements in threshing machines.* Dated December 1, 1862.

This invention consists in the use, peculiar arrangement, and novel construction of an endless band of cells or boxes for receiving the grain as it is discharged from the threshing cylinder; in the employment and novel construction of a revolving rake for the purpose of accelerating the movement of the straw after it has passed the said cylinder, and completing the separation of the grain from the straw; in the novel device for separating the grain from the chaff, consisting of a perforated riddle with serrated longitudinal ledges for supporting and carrying forward the straw, and one or more sets of agitating fingers operated for the vibration of the riddle; in giving the requisite movements to the perforated riddle, the grain board, and the sieve box by means of a single swing lever upon each side of the machine, actuated by connecting rods from the fan shaft; in the use of a flue extending from the front of the threshing cylinder, and communicating with the straw chamber for the purpose of creating a draught by suction, thereby carrying away the dust, and in forming and combining other parts with the above so as to secure compactness and cheapness in construction and economy in operating the machine. *Patent completed.*

3213. P. BOURNE. *Improvements in miners' lamps.* Dated December 1, 1862.

This invention consists in means for extinguishing the light of the lamp in the act of opening the lamp, and before the gauze covering can be removed from the lamp. For this purpose the inventor attaches to the lamp near to the wickholder an apparatus consisting of one or more levers, mounted on a suitable fulcrum, bearing, or bearings, and which apparatus is capable of being depressed on the wick by the act of removing the wire gauze covering. This apparatus is by the action of a suitable spring or springs, or by the weight of the short end of the lever or levers aforesaid, or by both of such means, kept out of the way of the ignited wick so long as the gauze covering remains on the lamp, or when the gauze covering is being placed on the lamp, but as soon as any attempt is made to remove the gauze covering, a small projecting piece (or pieces) attached to the mounting of the gauze covering is forced under the short arm of the lever (or of each of the levers if more than one), which short arm is thereby, and by the unscrewing of the gauze covering, elevated, and thus the other end of such lever (or levers) is depressed on the wick, and so the wick is pressed down and the light becomes extinguished. *Patent abandoned.*

3214. G. F. GRIFFIN. *Improvements in the permanent way of railways.* Dated December 1, 1862.

These improvements consist in lowering the rail into the body of the sleepers, using the curve or lateral arch of the sleeper to support the rail on one side, and forming jaws or chair-arms to support it on the other, by which means the patentee obtains greater strength and a larger bearing surface to prevent lamination of the rail. Further, the keys being placed inside, should one accidentally become misplaced, there would be no danger of the rail getting out of gauge. The improvements further consist in recessing wood the whole length of the sleepers under the rail, and placing wood in recesses in the jaws or chair-arms of the sleeper described in the specification of a previous patent granted to the patentee (No. 1,843) in the year 1861, especially recessing wood in the lateral arch above mentioned, and in the keys in such manner that the wood assists in supporting the rail under its head. The key is itself supported on a shoulder cast on the inside of the jaw, and, therefore, cannot be placed downwards. Where wood is not used the rail is supported by the lateral arch itself. *Patent completed.*

3215. T. WALLER. *Improvements in stoves.* Dated December 1, 1862.

The object of this invention is to enable the fire space in stoves to be contracted or to be opened to its fullest extent at will, and this without affecting any other part of the stove beyond the fire space. The invention consists in hinging or connecting the cheeks of that part of the stove comprising the fire space to the back in such manner that they may be moved towards each other to any extent desired, in order to lessen the space for fuel, and again moved from each other to the full extent of the fire space by in-

serting a poker or other tool into a long ring or hole formed on or in the cheeks. In order to prevent any material falling behind and obstructing the motion of the cheeks, the patentee boxes them. *Patent completed.*

3216. J. IRWIN. *An improved machinery for cultivating land.* Dated December 1, 1862.

This machine is designed, principally, to give the effect of ploughing and cross cultivating at one operation, but it may be used also with advantage for removing "twitch" or "couch grass" and weeds from land, and for manuring. The machine consists, principally, of a central frame, supported upon two wheels (about 3 or 4 ft. in diameter), and having a hinged frame at back and front, provided with a guide wheel fitted with a socket joint and a guide lever. The hinged frames have each two cross bars, the first carrying five coulters, and the second four shares or "shell boards." These frames are hinged or jointed to the central frame of the machine, and provided with a lever or other suitable mechanism, so that either frame can be raised whilst the other is lowered. *Patent completed.*

3217. R. FLUDE. *Improvements in looms for weaving narrow fabrics.* Dated December 1, 1862.

This invention relates to the means employed for driving the shuttles in looms for weaving narrow fabrics, and consists in the employment of one shuttle driver, with two upright levers for each shuttle mounted upon it; the upper ends of such levers carry pegs which enter holes in the front of the shuttle (one at either end), or the pegs may be fixed in the shuttles, and the levers be provided with holes or slots taking thereon. One or other of the driving pegs and levers is always in connection with the shuttle, which connection may be utilized to prevent the shuttle dropping in front, and which, therefore, in such case may be shorter than the shuttles usually employed. *Patent completed.*

3218. J. COPPARD. *An appliance or appliances for horse shoes, to produce the effect of what is termed roughing.* Dated December 1, 1862.

In carrying out this invention, the inventor makes what he terms a clamp of any suitable metal, of size and shape adapted to the toe of a horse-shoe, so that one part shall fit in between the shoe and the hoof at the toe, or be otherwise secured at this part of the clamp, the other part being turned up in front with flanges, eyes, or catches, and be further secured to the hoof by a strap or india-rubber band passed round the same, and binding the clamp finally thereto. This clamp is to have projections or a roughened surface, so as to give the requisite foot-hold, and the roughened parts may be of steel or hard metal, and may be in separate pieces, which can be inserted and removed as desired, packing being then introduced between the horse's hoof and the clamp. *Patent abandoned.*

3219. J. ROMER. *Improvements in manufacture of bullion wire and metallic fine-drawn wire.* Dated December 1, 1862.

This invention consists in manufacturing bullion and other wire, either of gold, silver, silver gilt, steel, iron, and other metals or alloys, by drawing them through or between diamonds, rubies, sapphires, topazes, crysolites, garnets, or any other oriental or hard stones. *Patent completed.*

3220. W. CLARK. *An improved apparatus applicable as a pump, water-meter, hydraulic motor, or a steam engine.* (A communication.) Dated December 1, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3221. P. W. REUTER. *The preparation of a new compound to be used for dyeing and printing purposes.* (A communication.) Dated December 1, 1862.

This invention consists in the preparation of a compound for producing a brown colour on wools, by mixing oxide of lead, or other compounds of lead, with lime, potash, carbonate of potash, soda, carbonate of soda, baryta, magnesia, strantia, or other similar substances, which, on being mixed with water, will form an alkaline solution of oxide of lead. *Patent completed.*

3222. E. D. JOHNSON. *Improvements in pocket watches.* Dated December 1, 1862.

The object of the first of these improvements is to construct what is known as the blind man's watch, or a watch which will indicate the time in the dark by the touch, without materially interfering with the movement or mechanism of the watch, or with the external appearance of the watch. In carrying out this object, the patentee arranges a train of wheels on the upper plate of the watch, the last wheel of which shall be situate in the centre of the watch, and revolve once in every twelve hours. This wheel he so constructs or fits that it shall present an obstruction to a catch or stop carried by a moveable disc forming a false back to the case. This catch or stop is so arranged that, when the disc is moved round in one direction, the catch will strike against the obstruction, and the further movement of the disc will be thereby arrested, but when moved in the opposite direction, the obstruction will not be presented. By arresting this disc or moveable portion of the case the position of the hour hand will be ascertained, a stud being provided on the exterior of the face of the disc to act as an indicator, and a series of studs representing the position of the hours on the dial being inserted in the rim of the watch case. *Patent completed.*

3223. B. OLDFIELD. *Improvements in looms.* Dated December 1, 1862.

We cannot here devote space to the details of this invention. *Patent completed.*

3224. A. V. NEWTON. *Improvements in the construction of steam and other vessels.* (A communication.) Dated December 1, 1862.

This invention relates to the construction of vessels of war and other ships by covering the framing with a material that will form perfectly water-tight joints, present great resistance to, and will not splinter by, the concussion of shot or shell, and will withal be materially lighter than plate iron. The following is the mode of preparing this plating or covering material:—The commonest paper pulp, such as that of the cheapest straw board, is mixed with a thin solution of marine glue (which is insoluble in water, and unchangeable by time or temperature), or with any other gum or resin suitable for insuring the firm adhesion of the pulp fibres. This compound is compressed in moulds to form sheets or slabs, say 10 ft. square and 1 ft. thick, until it attains the hardness of oak, or even a greater degree of hardness. Before the sheets or slabs are dry and set, they are to be twisted to the forms required to suit the various parts of the hull. Thus provided with suitably shaped slabs, the shell, skin, or covering of the ship may be rapidly built up, two or more thicknesses of the sheets or slabs being used the one to overlap the other, and break joints in all ways. These layers of covering material are to be both bolted and glued together to make a firm compact mass. *Patent completed.*

3225. H. TWELVETREES. *Improvements in apparatus for cleaning knives, forks, and boots.* Dated December 2, 1862.

For cleaning boots according to this invention, the inventor employs a small wood or metal frame, in form something like a table, and immediately under the top at one or both sides he mounts a shaft containing one or more circular brushes. These brushes may be separate and fixed upon the shaft by wedge or other means, or by preference they are part of the wood shaft, and the bristles put therein to form the brushes. In the centre of the table underneath the top he disposes a flat piece of wood perpendicularly, terminating at the bottom with a small shelf, and by this means the dust from the bolts are prevented being scattered about. Within the frame of the table underneath the brushes he disposes a fly-wheel and treadle, communicating by means of a strap or cord with a small pulley upon the brush shaft for giving rapid motion thereto. *Patent abandoned.*

3226. H. TWELVETREES. *An improved sawing, filing, working, and turning apparatus.* Dated December 2, 1862.

We cannot here quote the details of this invention. *Patent abandoned.*

3227. H. TWELVETREES. *Improvements in washing, wringing, and mangling machines.* Dated December 2, 1862.

We cannot here quote the details of this invention. *Patent abandoned.*

3228. P. BRASSERT. *Improvements in apparatus for saving life and property in cases of fire or burglary.* Dated December 2, 1862.

The apparatus, the subject of this invention, consists of a wicker-work basket, which the inventor makes of a convenient size to contain the other requisities and parts of the improved apparatus; as also to be suitable for an ottoman or seat. For this purpose, and to render the basket more or less ornamental, he covers it in any suitable material according to the position or to the room in which it is to be placed. He prefers to place it close up to the window. He places in the basket (which has a lid to lift up easily) a rope ladder, by preference of light wire cord, and with wood or metal rounds or steps. He also attaches to the top edge of the basket a double cord of a length according to the height of the house, and in the bottom of the basket he fixes an upright iron standard, with a strong hook at the top nearly level with the top of the basket, and near the same side as that at which the double cord before mentioned is attached. He fixes a strong hook inside the window sill, or in the wall, to which hook the rope ladder may be readily hooked, it having a suitable eye for the purpose. *Patent abandoned.*

3229. J. and J. CRAVEN and J. ROBINSON. *Improvements in looms for weaving.* Dated December 2, 1862.

This invention relates to circular or other change shuttle-box looms, and the improvements consist in a means or method of stopping the shuttle at the proper place in the box, so as not to prevent the free movement or changes of the boxes at the time required. *Patent completed.*

3230. G. F. BLUMBERG. *Producing designs in or on glass.* Dated December 2, 1862.

The object of this invention is the production of ornamental glass tiles or quarries, to be used for the purposes for which the well-known Dutch tile is used, and also for paving or for lining surfaces where an ornamental, as well as solid substance, impervious to damp or other corrosion, is required. The patentee makes the tile of any size that may be desired, from the square of 6 in. or less to the ordinary size of foot paving, and of any shape, and of forms permitting the tiles or quarries to fit, or, as it were, dovetail into each other. He manufactures tiles or quarries of glass of any form or dimension, producing thereon a design or designs of any nature or description. To effect this he prefers to employ a mould made either of steel, iron, brass, copper, or other suitable metal or amalgam capable of taking a high polish, as he prefers to use a mould free from all irregularities and of plane polished surface. If the tiles, quarries, or slabs be of large size, a casting-table may be used, and the cavities for the designs made by a roller prepared for that purpose. *Patent completed.*

3231. J. WHEATLEY. *Improvements in the construction of ships-of-war, and in the manufacture of armour plates for ships, forts, and batteries.* Dated December 2, 1862.

For the purposes of this invention, in constructing a ship-of-war, the patentee forms the bow with a sharp projecting grab or crab bow, at an angle of about 25 deg. with the keel, and propels the vessel by paddle-wheels and screw, or by screws, the wheels when used working independently, so as to steer the vessel thereby. The rudder is to be supported by chocks acting like a common vice. In order to be able to mount guns of large calibre and power (say 13 in. bore, and 20 tons weight) in or near the centre of the vessel, pointing in a line with the keel, he constructs a glacis plated over with armour plates, and over the whole fore part of the vessel and extending to the front of the paddle-boxes. Another part of the invention consists in a mode of manufacturing armour plates, for which purpose the armour plates are to be rolled or formed with external parallel projecting ribs or lattice-work, at a distance apart less than the diameter of a shot or projectile which would be thrown against a ship, fort, or battery, protected or coated with armour plates, with the knowledge that the same would pass through the plating if of the ordinary construction. *Patent completed.*

3232. T. COOK. *Improvements in envelope folding machinery.* Dated December 2, 1862.

This invention consists in applying to such machinery apparatus arranged as hereinafter described for collecting the envelopes after they have been folded. A trough or slide is placed below the box in which the envelope has been folded, so that the envelope drops down this trough into a frame. A slide worked by a lever then carries the envelope over a grating having the ends open on one side. At each operation a lever or rake, having fingers which will pass between the bars of the grating, lifts the envelope up, carrying it into a trough of a suitable size. By this raising of the lever another envelope is allowed to be passed underneath this last mentioned lever or rake ready for it to lift at the succeeding operation. *Patent completed.*

3233. G. T. BOUSFIELD. *Improvements in forming the permanent way of railways.* (A communication.) Dated December 2, 1862.

For the purposes of this invention double T or H angle iron is used as sleepers or transverse bearers, in place of those heretofore employed, and also when continuous bearers are used. These forms of sleepers or bearers are employed whether chairs or other means of fixing the rails to the sleepers or bearers are resorted to. In forming a permanent way according to this invention, the sleepers or bearers are usually placed transversely across the railway, and the rails are fixed by bolts and nuts to the transverse sleepers or bearers. The chairs may be either fixed directly to the sleepers or bearers, or wood, or other suitable packing, may be interposed between the under surfaces of the chairs and the upper surface of the web which comes between the flanges of the double T or H angle iron of the bearers or sleepers, which are laid in a horizontal position on the earth. *Patent abandoned.*

3234. G. T. BOUSFIELD. *Improvements in apparatus for discharging guns or ordnance.* (A communication.) Dated December 2, 1862.

This invention consists in the employment upon the exterior of the gun of certain devices which enclose the vent and primer with sufficient strength to retain the gases of the discharge, and which can be readily removed and replaced to permit all the operations of loading and priming, or to enable the vent to be used in the usual manner in case of accident to the vent stopper, or the absence of proper primers. These devices consist, substantially, in forming upon the exterior of the vent a recess or receptacle for containing fulminating primer, and employing therewith a sett or plug, which the inventor calls a vent stopper, which closes it, and is confined thereto by some efficient means; and a fulminating primer provided with a casing of thin copper, or other suitable material, which, by its expansion against the sides of the recess or vent, closes the joint to the escape of gas. The primer is ignited by a blow applied to the exterior of the sett by a lock or otherwise. *Patent completed.*

3235. D. GRAHAM. *Improvements in steering and manœuvring ships or vessels, and in the apparatus employed therein.* Dated December 2, 1862.

In carrying out this invention, under one modification or system of arrangement, an opening is formed in the stem or "dead wood" at the forward part of the vessel, and in this opening is fitted a retangular or other suitably shaped rudder; or instead of being fitted in an opening in the ordinary stem, the rudder may be set to project forward beyond this stem. This rudder or steering apparatus is fitted on a vertical shaft which passes down through the central part of the rudder, and is stepped in a footstep bearing arranged for the purpose in the framing of the opening, and which extends in a line with the lower part of the keel. The rudder may, however, be fitted up and actuated in various other ways. The shaft is carried up on deck, from which point it is suitably connected to a steering wheel by means of bevel or other equivalent gearing. The former rudder made to be made supplementary to the usual one at the stern, or the vessel may be wholly steered by it. *Patent abandoned.*

3236. A. P. CHARLES. *Improvements in candles and night lights, and in the lamps or apparatus for burning the same.* Dated December 2, 1862.

This invention relates—1, to that class of candles and night lights in which a large illuminating power is not required so much as a continuous light of feeble power for a small expenditure of fatty matter. This part of the invention consists in making candles and night lights of considerable thickness and length, and with thin wicks, so that they may burn for a greater number of hours, and when extinguished, after burning as long as may be required for the time, may be readily lighted again, and so on until the whole of the candle or night light is consumed. The patentee makes night lights and bedroom candles with very thin wicks, surrounded by a very considerable body of tallow or fatty matter, and of such a length that they will last from 30 to 40 or more hours. Such candles or night lights will not, however, burn like ordinary candles, and they require the assistance of some contrivance or apparatus to prevent the melted tallow or fatty matter from spilling or guttering, and thereby wasting the candle. This apparatus in its various forms constitutes the second part of the invention, and consists of a small cup of any suitable shape adapted to a tube which forms a nozzle or cap, and is placed on the candle. This nozzle by its own weight descends on the candle as the tallow burns away, the cup acting as a reservoir to hold the melted fatty substance. *Patent completed.*

3237. R. K. CAUTLEY. *Improvements in electro-thermal baths.* (A communication.) Dated December 2, 1862.

This invention consists in the novel construction and arrangement of the parts of an electric bath, whereby the current of electricity is more perfectly controlled and more

conveniently and advantageously applied to the human body for the cure of disease. *Patent abandoned.*

3238. H. J. SIMLICK. *Improvements in the manufacture of cigar and pipe lights.* Dated December 2, 1862.

In carrying out this invention, the inventor proposes, instead of forming the holders of these lights of glass, wood, clay, or wood and straight wire combined, to form such holders of spirally-twisted wire, or strips of metal, the coils of which are to be slightly opened or separated, in order to allow of the circulation of air between the coils. *Patent abandoned.*

3239. B. BROWNE. *Improvements in the construction of knobs or handles of door locks, and in the mode of constructing same with the sliding bolts thereof for advancing and drawing locks and bolts.* Dated December 2, 1863.

In carrying out this invention, the inventor employs a knob working on a fixed axis, and fixes therein a short crank or arm, formed with a small pin which fits in a vertical groove made in the bolt, so that, by turning the knob in a semicircle in the said goove, the bolt will be moved by the said pin in a straight line either backwards or forwards, either for drawing back or pushing forward the bolt, and will retain the same firmly in either position, thereby dispensing with the use of a spring for pushing the bolt out, as heretofore practised, and by these means keeping the bolt within the lock when the door is opened, instead of the bolt projecting beyond the edge of the door, as is now the case, and which in practice is found very objectionable. He employs a spring to press on the edge of the crank or arm aforesaid for keeping the same steady. *Patent abandoned.*

3240. H. WYLDE. *Improvements in electro-magnetic telegraphs, and in apparatus connected therewith.* Dated December 3, 1862.

This invention is not described apart from the drawings. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated February 18, 1863.

448. G. T. Bousfield, Loughborough Park, Brixton. Improvements in the manufacture of boots and shoes, and in preparing india rubber for such and other uses. (A communication.)

Dated March 5, 1863.

626. T. W. Osborne, Aston New Town, Warwick, lamp maker. Certain improvements in lamps.

Dated March 11, 1863.

659. H. Fletcher, Manchester, engraver and mechanician. Improvements in cleaning and preparing cotton for spinning.

Dated April 22, 1863.

1002. H. B. Barlow, Manchester. Improvements in shoes, boots, and other coverings for the feet. (A communication.)

Dated May 14, 1863.

1216. L. S. Chichester, Brooklyn, New York. Improvements in machinery for weighing grain.

Dated May 25, 1863.

1315. J. Hilliar, Cheapside, manufacturer. Improvements in the construction of the frames, sashes, shutters, blinds, and ventilators for windows or other openings, parts of which improvements are also applicable to other constructive purposes.

Dated May 26, 1863.

1326. F. W. and J. Kitson, Leeds. Improvements in the manufacture of the tyres for railway wheels, and in the means of securing the tyres to the wheels.

Dated June 4, 1863.

1396. H. Pollack, Hamburg. An improvement in the manufactute of scarlet, brown, and orange colours.

Dated June 5, 1863.

1404. J. Seaman, Worcester. Improvements in implements to be used in the cultivation of the soil.

Dated June 8, 1863.

1408. R. Wallis, Basingstoke, corn and coal merchant. Improvements in apparatus for loading and unloading vessels, and for elevating and otherwise conveying sacks, casks, and other packages, parcels, or objects from one locality to another.

1414. W. Miller, 70, Upper Stamford-street, Blackfriars. An improved mode of constructing ships, vessels, or boats, and of apportioning their freight to that construction, so as to prevent their sinking or being destroyed by fire.

Dated June 11, 1863.

1448. M. Hatschek, 32, Lower Belgrave-place, distiller. An improved method of mashing.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated June 19, 1863.

1536. H. A. Bonneville, 24, Rue du Mont Thabor, Paris. Improvements in machinery for the manufacture of bolts and rivets. (A communication.)

LIST OF SEALED PATENTS.

THE MECHANICS' MAGAZINE.

Contents of the Last Number:— PAGE

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JULY 10, 1863.

THE TRIAL OF STEAM FIRE-ENGINES.

IN our last number, we mentioned that the trials, commenced on Wednesday, were continued on Thursday. The engines having to draw water from a depth of 16 ft., and to force it into a hood fitted into the side of one of the water temples, through a considerable length of hose. The tank into which the hood delivered was calculated to contain 18,000 gallons, and the heights and distances were as follows:—From the surface of the water to the landing on which the engines stood, 16 ft.; from the level of landing to the rail which supported the jet pipes, 28 ft.; from the level of the water, from which the engines pumped, into the hood, 79 ft.; distance, in a direct line from the engines to the hood, 383 ft.

These particulars will show that the test was no common one, and was well calculated to try the abilities of the competing engines in the severest manner. We stated that Messrs. Shand and Mason, and Messrs. Merryweather, accomplished their allotted task in a way which left little to be desired; proving conclusively that, even under the most trying circumstances to which steam machinery of the kind can be exposed, it is capable of doing good service. Messrs. Easton and Amos' engines, from some cause, failed to draw water; indeed, the mere fact of propelling the water through a long stretch of hose was by no means the principal difficulty. Fire-engines are designed for forcing, not drawing water, and a clear lift of nearly 19 ft. into the pump barrel was a test, such as they were neither intended for, or likely to be called on to repeat during the fulfilment of their missions. The American engine drew water almost at the first attempt; but, unfortunately broke down, with a smashed cylinder lid, before it had been many minutes at work. Short as the time was, the quantity of water lodged in the tank was sufficient to demonstrate the enormous powers of the machine.

The "Manhattan," in being brought to its place on the day previous to the commencement of the trials, was, unfortunately overturned in the gardens, smashing its fore carriage almost to pieces, besides breaking one of the fly-wheels and cracking the other. The piston rod of this engine is fitted with a long cross-head, which carries two connecting rods, which return along the sides of the cylinder, and lay hold of pins set in two small fly-wheels, mounted on the shaft of a rotary pump. The nave of the destroyed wheel remained uninjured, and with it the crank pin at that side; but the opposite wheel was cracked through the centre boss, although the rim held together. The boiler not being injured, the front end of the engine was mounted on a four-wheel truck, in lieu of the proper fore carriage, and without taking any part in the competition for the prizes, the "Manhattan" got up steam on Thursday, and displayed powers sufficient to convince many that, if in good order, English builders would have found it anything but a despicable rival. A few minutes' work, however, caused the crack in the fly-wheel to spread so much, that the fire had to be drawn to avoid further mischief.

On Friday, the small engines were submitted to almost precisely the same test as that which their larger brethren had already undergone the day before; the same height of lift, the same length of hose to force through, the same hood and tank to pump into; the sole difference being, that instead of filling the tank quite full, which would have occupied much time, each trial lasted one hour, at the termination of which the depth of water lodged in it afforded a means for comparing the relative merits of the competitors. The competing engines were—Mr. Roberts' "Princess of Wales," Mr. Merryweather's "Deluge," Mr. Lee's "Alexandra," and Messrs. Shand and Mason's small engine. Mr. Roberts' was the first to draw water, almost at the first attempt, going on steadily, without stop or interruption, until his task was accomplished. The rate of the engine was very even; the steam easily maintained at 80 lb. to 100 lb., without any excessive firing; the water level very steady; and the supply of steam abundant and free from priming. The jet thrown was very good, being close, compact, and without air spurts. Owing to a defective rivet giving way, in a stay which steadied the crank shaft bearing, a certain amount of caution was necessary, as the slightest approach to over-driving would have inevitably led to a break-down; but notwithstanding this mischance—if the incident deserve the term—the engine continued and ended its undertaking after a very excellent fashion.

Mr. Roberts' trial concluded, Messrs. Merryweather got their small engine to work, after some difficulty, the presence of air in their suction pipes being rendered apparent every now and then by a crackling spurt in their jet. The performance of this little machine was, nevertheless, on the whole, satisfactory; and although some little trouble was experienced in keeping up the steam at first, yet there never was a sufficient reduction of pressure to render a stoppage imperative. After all, the question of keeping steam rests so completely on the skill of the stoker, that it is really a very imperfect test of the powers of an engine. Most of the stokers, too, employed on the occasion, were comparatively new to their work; and we can assure our readers that firing an engine of the class exhibited, is a very different affair from anything else which generally falls within the province of those who have to deal with furnaces. Thus, engines which on the first day of trial could scarcely keep their steam up to 60 lb., found no difficulty on subsequent occasions in doubling that pressure, with a corresponding increase in the amount of work done.

Mr. Lee following Messrs. Merryweather, got to work after some delay, and continued steadily to the end; the steam pressure easily maintained at 80 lb. to 100 lb., without excessive firing.

Although Shand and Mason had already performed all that was required for the purpose of competition with their large engine, they got up its steam on Friday, and tried again at the 16 ft. lift. After two or three attempts they got water, and threw one very beautiful perpendicular jet close to the engine. Stopping for a few seconds, some difficulty was experienced in getting to work again, which indeed was not accomplished until two jets were substituted for one, in order to permit such a reduction of pressure in the air vessel, as enabled the engine to start freely at a high speed. The nozzles employed were one of 1 in., the other 1⅛ in., diameter; the jets thrown solid, steady, and very even in height. Their elevation could not have been much less than 120 ft.

Messrs. Easton and Amos' engine, the "Sabrina," standing on the bank of the lower pool, and drawing its water from thence, threw two splendid jets for an hour at a time. Horizontally or vertically directed, the distances reached were immense; and the jets, although occasionally fitful and scattered, were for the most part compact and of good quality.

Messrs. Shand and Mason, after a little time, withdrew their large engine, which had been playing much more for pleasure than business for more than an hour, in order to make room for their smaller engine. At the commencement of the competition on Friday morning, this machine had been one of the first, if not the first, to draw water; but a mysterious handful of shavings in the suction-pipe, rendered it inoperative for a time, compelling the removal of the foot-valve in order that it might be properly cleaned. This circumstance had, of course, occasioned a considerable delay, which the proprietors were anxious to make up for. But for a time the engine started, and re-started in vain. No water could be drawn. Another examination of the suction hose revealed the cause. The india-rubber tubing, instead of having the brass wire distending-rings inside of all, had yet another coat of india rubber within these. This inside lining had, under the pressure of the atmosphere, collapsed, being torn away from the wire. Thus the tube, perfect outside, was really completely stopped within, and as there was no other hose on the ground, with unions which would suit the pump, Messrs. Shand and Mason had to send to London for fresh couplings, so that the engine did not really get to work until nearly 7 o'clock in the evening. It then played into the large tank for an hour without intermission, throwing a beautiful jet. Steam was kept at 140 lb. to 180 lb. without the slightest difficulty; the engine making 120 to 130 revolutions per minute, the fire-door, indeed, being open a considerable portion of the time. Such a repetition of misadventures were sufficiently vexatious, as, no matter what the real state of the case may be, the general public are apt to draw erroneous impressions. Most of the visitors, too, had gone, leaving however a small number of those, whose good opinion was best worth having, behind.

We have yet to describe the most exciting contest which took place at any time during the three days (ever to be remembered in the annals of steam fire-engines) which the competition lasted.

At about 5 o'clock Messrs. Merryweather's large engine "Sutherland," Mr. Lee's "Victoria," Messrs. Shand and Mason's large engine, and Mr. Roberts' "Princess of Wales," the same we have already partially described, proceeded to the north water-tower, in order to test their powers of throwing vertical jets. Suitably placed on the gravel walk, in front, their suction hose pipes were lowered through holes broken in the boundary wall, into the large pond outside. The delivery hose was led round to the back of the tower, where a rough frame and scaffold had been provided. To a suitable cross-rail on this, 10 ft. perhaps, above the level of the engines, the jet-pipes were firmly lashed, in a vertical position, close (we thought too close) together. By this arrangement it will be understood that the jets rose perpendicularly, and parallel to the tower, whose ten floors afforded an admirable scale of comparison for the competitors.

Messrs. Shand and Mason, first ready, commenced with a jet 1⅜ in. in diameter, attaining at their first trial an altitude of about 100 ft., with a very low pressure of steam. Stopping, from some mistake, for a couple of minutes, they, on recommencing, easily threw a jet of about 170 ft., but finding themselves overtopped by Messrs. Merryweather, who had

also got to work by this time, they raised steam to 120 lb., and, with this pressure, succeeded in throwing a magnificent solid jet to a height of over 180 ft., quite overtopping Merryweather's jet for the time, but the boiler proved too small to maintain the supply of steam necessary for such an extraordinary exertion, and after a struggle, exciting and well-contested in the extreme, they gave way to Messrs. Merryweather, who attained a height of 180 ft. with a nozzle of 1½ in. in diameter, keeping up this tremendous stream with a force and power which rendered it magnificent. In fact, it seemed as if the "Sutherland" had never properly got to work before. The jet was solid, and without air. The engine maintained its speed with great regularity, the steam pressure varying very little from 100 lb., without excessive firing, and that in the air vessel fluctuating at each stroke of the pump some 8 lb. or 10 lb., or from 80 lb. to 90 lb. It was evident that the engine could keep on all night, just as well as for the time the trial lasted.

Mr. Lee's "Victoria," to our surprise, did almost nothing. Getting to work soon after Shand and Mason, a considerable space of time elapsed before any water appeared at his jet-pipe, and when it did come, the volume, although of good diameter, scarcely exceeded a height of 50 ft. We understand since that the piston, which is of steel and very thin, was seriously injured by the accident on the previous day, which quite accounts for such a result.

Mr. Roberts, who had kept his fire banked up since the trials in the forenoon, was one of the first to start; but his engine had not made two revolutions, when the upper feed-pump valve became gagged by a small fragment of iron. Removing the caps and cleaning the pump occupied some time, the others being ready to cease operations by the time the "Princess of Wales" began. Nevertheless, she did not forfeit one tittle of the good opinion already earned, throwing a ⅞-in. jet from 120 ft. to 150 ft. high. Had the experiment continued, we feel little doubt that still better results would have been obtained, but the lateness of the hour brought all further trials to a close. The comparative weights considered, however, we will find that the performance of this little engine was as good, *cæteris paribus*, as that of either of its heavier adversaries.

In our last week's number, we gave our readers a somewhat hasty and imperfect description of the various engines exhibited. We are now enabled to supply some further information, which we look on as extremely interesting. Steam fire-engines are a novelty in engineering; and the trial of last week is, to a certain extent, fully as remarkable as the memorable one at Rainhill, which first brought the locomotive into public favour. It has not only been a trial of what different engines could accomplish, but of what steam power, under the most abnormal circumstances, could achieve; and it is scarcely possible to conceive an experiment, which could more fully illustrate that wonderful flexibility of application—if we may use the phrase—which renders the steam-engine useful under every possible circumstance or situation. As the representatives, too, of a description of machinery almost unique in this country, everything regarding these engines is of interest and importance to the engineer. Whether their manufacture will ever become as extensive in this country as it has in America, is a question which interferes very little with the value of the lesson conveyed. Day by day we find an increased tendency on the part of engineers to reduce the weight of their machinery, and here we find engines capable of giving nearly an effective horse power for every cwt. of dead weight. The lesson to be drawn, scarcely requires comment at our hands, and we feel little doubt that the past trial will bring forth good fruit in due season.

The following are some of the principal dimensions and particulars of Shand and Mason's small engine:—The upper part of the boiler is cylindrical, of Bowling "best best" iron, one-fourth of an inch thick, welded, 2 ft. 1 in. in diameter outside, and about 2 ft. 6 in. high. The upper part, turned to a round flange, is bolted to a suitable plate, through which the up-take, 8 in. in diameter, passes. The lower part has a Bowling 2½ in. angle iron ring riveted round it. The fire-box shell is conical, 2 ft. 1 in. in diameter at the small end, which is fitted with a precisely similar angle iron ring, and 2 ft. 10 in. in diameter at the larger, outside, giving a diameter of circular grate of 2 ft. 7½ in. Both rings are accurately turned and faced in a lathe, so as to make a perfectly steam-tight joint, by the aid of a little red lead, when bolted together. The inside fire-box is of iron, of the same thickness, the top, which forms the tube plate excepted; this last being also of iron, but ½ in. thick. The vertical tubes are 195 in number, 1 in. in diameter outside, 12 in. long, and No. 19 wire-gauge thick, fitted without ferrules, by simple drifting. They are spaced only one-fourth of an inch asunder, and deliver the products of combustion into a smoke-box, about 5 in. deep, quite covered with water. From the centre of this smoke-box rises the up-take, surmounted by a handsome brass-stopped stack, 2 ft. 9 in. high. The distance from the grate bars to the tube plate is 2 ft., the height of the boiler over all about 4 ft. 6 in., the bottom clearing the ground about 15 in. By unscrewing the bolts which connect the angle irons, and those which unite the upper flange with the top plate, the entire cylindrical shell can be removed, permitting access to every portion of the interior of the boiler, tubes, smoke-box, &c., an advantage of the last importance. A space of some four inches, however, unavoidably remains between the boiler shell and the outer tubes, because the shell could not be drawn over the smoke-box, if its diameter were narrowed in order to approach the tubes. An unnecessary body of water would, of course, remain here, but for the following ingenious expedient:—A species of copper "pocket"—we cannot think of a better name—descends nearly to the crown of the furnace, all round between the shell and the outer tubes, displacing the water and supplying so much additional steam space, for the upper edges of this pocket are considerably above the water line. The boiler, in fact, carries steam below the water. Of course, no pressure except that due to the gravity of the liquid is exerted on the sides of the pocket which are traversed by the pipes leading to the gauges. The contrivance is extremely simple and answers its purpose admirably. A copper ring, drilled with a multitude of holes, surrounds the up-take, and supplies the steam to the cylinder through a copper tube 1¼ in. diameter, fitted with expansion joints. The exhaust steam pipe is 2½ in. diameter, terminating in a variable exhaust, not easily described without drawings; suffice it to say, that the orifice can be enlarged or contracted, by means of a hand-screw, being equivalent in area to a circle 1¼ in. in diameter when full open, and to one of ¾ in. when shut.

The pump is fitted with six india-rubber disc valves in the bucket, and, seven in the foot valve plate. This last can be removed in a few minutes, when by turning a nut the bucket can be withdrawn for examination or repair.

The fire-box is provided with two fire-doors—one behind, and the other at an angle of 45 deg. just in front of the hind wheel. A person standing on the foot plate behind, can fire the boiler when proceeding through the streets; the 24 ft. of suction which the machine carries ready screwed on, being coiled round the engine out of the way. On reaching the fire this door is shut, and the front wheels locked round. The other door, then become easily accessible; a small coal bunker being hung from the front axle, in a convenient position for the stoker. The weight of this engine as entered for the trial was 1 ton 9½ cwt.

We manage our commercial transactions now-a-days in a way little dreamt of fifty years ago. This machine has been sold, through the medium of the telegraph, for the use of one of the imperial palaces at St. Petersburg.

The boiler of the large engine, by the same firm, is almost precisely the same, in every respect but size, as that we have just described, the number of tubes being 328, 1 in. in diameter outside, and 14 in. long, divided into four groups, in order to permit freer circulation. The top plate of the smoke-box is strengthened by 8 tubular stays, 1¼ in. in diameter inside, which suspend it from the top of the boiler, being screwed into the smoke-box plate, and stopped by suitable screwed caps at the other end, outside the shell. These stays act as additional heating surface, although there is no current through them. There are no very remarkable features presented by the engines or pumps, the dimensions of which we have already given.

The valve-gearing of Messrs. Merryweather's "Sutherland" is very remarkable, if not unique. "On the middle of each piston-rod is keyed a boss carrying a short arm projecting horizontally. Parallel to and at a short distance from each piston-rod, are fixed in suitable bearings, so as to be able to revolve freely on their axes, two twisted bars or quick screws, having a pitch of 1 turn in 16 inches. At the ends of these twisted bars or screws, next the steam cylinders, are cut two strong square-threaded screws, having 1 turn in 1¼ inches, on to which are fitted two gun-metal nuts, which nuts are received by the forked ends of the weigh-shaft levers for moving the slide-valves. To the short arms on the piston-rods above mentioned, are attached two gun-metal sliding pieces, which clasp, and move freely on the twisted bars or screws, and having the same motion as the piston-rods, impart a slow, easy, reciprocating rotating motion to the twisted bars or screws, causing the gun-metal nuts and weigh-shaft levers to be brought backward and forward with a slow, easy action, thus moving the slide-valves into the required position—viz., that of closing steam and exhaust ports shortly before the end of the stroke, thus preventing the possibility of striking the ends of the cylinders—it will be clearly seen that, by this arrangement, each cylinder cuts off its own steam and exhaust, and is entirely independent of the other for forming the cushion required to stop the momentum of the pistons; thus, *each piston brings itself to rest;* but when at half-stroke, by means of a connection between the weigh-shaft levers, gives steam to No. 2 cylinder, the piston of which brings itself to rest, and liberates No. 1 piston, and so on alternately.

"The slide-valves are of the equilibrium piston form, and with full steam (150lb. per square inch) can readily be moved by the hand with a force of 5lb., thus saving power which is more usefully employed in forcing water."

The following are the awards made by the Committee:—

LARGE CLASS.

Messrs. Merryweather and Son, first prize ... £250
Messrs. Shand and Mason, second ditto. 100
Mr. Roberts, honourably mentioned.

SMALL CLASS.

Messrs. Shand and Mason, first prize ... £250
Messrs. W. Lee and Co., second ditto. 100
(Signed) EYRE M. SHAW, Hon. Sec.
July 8th, 1863.

In another portion of our present number will be found so much of the official report as bears on the relative performances of the different engines. The complete report is too long, able, and exhaustive for insertion this week. The different items are sufficiently suggestive; and if the results of the competition do not prove satisfactory to all parties, we trust they may lead to another trial, from which, we feel certain, equally valuable conclusions can easily be derived.

TITANIFEROUS IRON ORE.

THE reduction of the titaniferous iron ores—found in the form of sand on the shores of the Black Sea, the Bay of Naples, and also along the shores of New Plymouth, in New Zealand—has lately engaged the attention of practical metallurgists to a considerable extent. Several companies have been formed in the City with a view of working these deposits with profit; and considerable sums of money have been spent in experiments conducted with a view of arriving at some means of converting this rich and valuable ore on a large scale.

We have examined different specimens of this peculiar metallic sand; from the shores of New Zealand; from Poti, in Asia Minor; and from Naples. They have all a similar appearance, that of fine steel filings, and they are strongly attracted by a magnet. The Italian specimen is somewhat mingled with common sea-sand or silica. The great value of these ores is due to their large percentage of iron, to their freedom from sulphur, phosphorus, &c., and to the presence of titanium itself in the form of an oxide. There is little doubt that steel is considerably improved by a mixture with titanium; and it is not improbable that the presence of this metal would also raise the quality of cast iron. The wonderful temper and tenacity of the sword blades of the Japanese are said to be partly due to the presence of titanium in the steel of which they are manufactured. It is stated by recent travellers in Japan that all the iron of that country is made from this peculiar sand. The sword-blades used by the Circassians are also made from the titaniferous iron ores of the country, and according to well-authenticated accounts their temper and durability is something marvellous. Of course, the mere presence of titanium does not wholly account for excellent quality of the iron manufactured by these semi-barbarous nations; the ore itself is pure, and it is always smelted with charcoal.

The most common mineral containing titanium is this titaniferous peroxide of iron. It is very similar in appearance to the magnetic oxide of iron, and it is, indeed, often mistaken for the latter mineral. Titaniferous iron ore is found in small quantities in Cornwall. Its scarcity has prevented its adoption up to the present in practical metallurgy; and this is also the reason that the metal titanium has been only discovered within a recent period. The titaniferous oxide of iron of the secondary formations has always the appearance of black-grained sand, the particles of which are attracted by the magnet. For a long time the titanium was only known in the form of an oxide. It has been found united with nitrogen and carbon in the slag from the blast furnaces of the Merthyr Tydvil iron works, in the form of well-defined prismatic crystals, of a copper colour. The various titaniferous iron ores contain from 13 to 52 per cent. of oxide of titanium in union with oxide of iron. Metallic titanium is somewhat similar in appearance to brass. Up to the present the principal application of titanium has been in the form of titanic acid for painting porcelain. It is used to produce a pale yellow colour.

It will be at once seen that the great obstacle to the reduction of these peculiar ores on a large scale consists in their being generally found in a state of minute subdivision. It would be impossible to feed a blast furnace with such a material. Although a large amount of capital has been spent in experiments, we believe that, up to the time we write, no ready means have been found to make the sand cohere in masses large enough for the free passage of the blast. The experiments have been conducted by several eminent metallurgists, but the investigations have been necessarily secret. It is not improbable that bricks of the necessary tenacity might be formed of this material by the use of a "high-pressure" brick-making machine. A process of baking with an appropriate flux might also arrive at a similar result. Mr. Mushet has made some first-class steel from this ore; but the process was carried out in crucibles with their attendant expense. The steel was shown in the Sheffield Court, and in the New Zealand Court, of the late Exhibition.

Should the hopes prove well-founded that an admixture of this ore with our English makes of iron would improve the quality of the product, this fine sand could be injected through the tuyeres into the furnace by means of the blast. This process has been already carried out with powdered charcoal, and also with pulverized calcined iron ore. It is evident that the attainment of a profitable means of reducing this rich and pure ore is merely a question of time and well-directed capital. It may buoy up the hopes of those who have spent large sums in, as yet, unfruitful experiments, to remember that the ordinary processes of manufacturing—flowing on with the ease due to long practice and experience—have themselves been evolved from a costly process of trial and error.

ANALYSIS OF BOILER FEED-WATER.

THERE is no necessity to inform a user of steam power, that the deposits and their resulting hard incrustations in steam boilers are continual sources of loss and annoyance. Not merely does the presence of scale interfere with the conducting powers of the boiler plate, preventing the free circulation of the water, and thus causing much heat to flow uselessly up the chimney stack; but a progressive deterioration of the boiler itself is induced by the presence of these deposits. The plates get burnt, and lose their strength through being thermally insulated from the water, while some deposits exert a chemical influence towards thinning the plates from the inside. At one time the presence of boiler scale was believed to be a direct cause of explosions; the disruption and splitting of this formation, with the resulting sudden influx of water on the overheated plates, was believed to be sufficient to cause an explosion. Although this theory is now rejected, the incontrovertible deterioration of steam boilers through the presence of scale, is sufficient evidence to warrant the assumption that boiler incrustations take the lead in a train of causes annually involving much destruction of human life. All these effects are, however, gradual, and their daily passage may be unnoticed by an untutored eye; but the expense of cleaning a boiler, and the consequent stoppage of operations, are sufficient reasons to make the most ignorant user of steam power think seriously towards providing a remedy for this continual drain on his pocket. The ordinary way of cleaning a boiler, by chipping off the hard scale by means of chipping hammers, is of itself a remedy that—while staving off the disease—at the same time debilitates the patient. When incautiously done, the operation injures the plate, by thinning it and by jarring the whole structure. In searching for a sound remedy, he encounters a rather great *embarras de richesses*. Mechanical, chemical, and chemico-mechanical remedies, are offered him on all sides. The chemical composition of water is very varied, and it is evident that an efficient remedy at one place may often loose its efficacy a few miles further on. The best way to meet an enemy you may have to encounter for years, is to get as much knowledge of him as possible; in this case, the penalty of ignorance is perhaps loss of life, while it is most certainly loss of property. A want of due knowledge of the causes that lead to the formation of boiler scale is evidently the reason that many good remedies have been wrongly applied.

It is thus apparent that in many cases, the wisest, and in the end, the most economical plan, is to submit the feed-water to the analysis of a competent chemist. This is often very inconvenient, and sometimes even impossible. There are, however, means by which an intelligent workman can ascertain, with tolerable accuracy, the chemical composition of the feed-water of his boiler; the knowledge of which can direct him to the choice of the proper means to meet his special case.

Most spring and river waters contain, in solution, varying proportions of lime, soda, magnesia, and other minerals. The most generally met substances, however, are sulphate of lime (plaster of Paris or gypsum), and carbonate of lime (common chalk); and these also form the most dangerous incrustations. The latter mineral is the one most commonly found in spring water in combination with carbonic acid gas. The presence of this acid enables the water to hold the chalk in solution; on its being driven off by the application of heat to the water, the chalk is precipitated to the bottom. Several plans for purifying feed-water are formed on this principle; one of these inventions was exhibited in the French Department in the Western Annexe of the late Exhibition.

The power of water to hold sulphate of lime is also diminished when its temperature is raised. Thus, 100 parts of water, at 77 deg. Fahrenheit, can dissolve 0·254 per cent. of sulphate of lime, but at boiling point the same amount of water can only hold 0·217 per cent. of this substance.

Dr. Van den Corput, in a paper on boiler incrustations, in the *Bulletin du Musée de l'Industrie*, of Brussels, gives the following practical chemical method for ascertaining with more precision the amount of the "hardness" of water, as it is popularly called; a state generally caused by the presence of the above ingredients. Water, containing carbonate or sulphate of lime, has the property of more or less precipitating solutions of soap. This will be noticed by most persons who use hard water for their daily ablutions. Sebasic alkaline salts are changed into sulphates or carbonates, and into an unsoluble chalky substance. The latter opalizes in the dull liquid, or, assuming a granular consistency, it swims on the surface of the water. These appearances give a means of ascertaining the amount of hardness of the liquid; and it can thus be determined from the dulness of its appearance,

and the amount of the chalky matter precipitated.

The process simply consists in pouring, drop by drop, an alcoholic* solution of soap into a determinate quantity of water, by means of a graduated glass. This must be continued until the chalk or the salts of magnesia generally present are completely separated, when a frothy appearance will be noticed on the surface of the liquid. This appearance determines the moment when the operation is finished, and the chalk is completely separated. The *proportionate* amount of the solution used to produce this effect—which is read off the scale of the graduated glass—determines the relative amount of chalk contained in the water.

We mentioned above that water when heated was able to hold less sulphate of lime in solution than when cold. This phenomenon affords us a means of ascertaining with some degree of certainty whether the feed-water is impregnated with more carbonate of lime than sulphate of lime, and *vice versâ*. The alcoholic solution of soap we have referred to above is mixed drop by drop with two separate and equal volumes of water. One of these mixtures must undergo the process of boiling and filtering. The quantity of the soapy solution required to cause a foaming appearance on the top of the water, when shaken up, it will be much less than that required for the other portion which has not undergone the boiling and filtering processes. This assay will answer even if the water contains lime in the form of chloride of calcium. This latter salt does not form a hard incrustation, and its presence is not so dangerous as that of sulphate of lime. The latter substance generally falls in the form of amorphous gypsum; but sometimes in small crystals of hydrated gypsum, forming the worst description of scale. Under long exposure to a high temperature, it becomes changed to anhydrite, having the crystallized form and the hardness of the natural mineral.

MACHINE FILE-CUTTING.

THERE are certain processes in the industrial arts which have hitherto set every attempt at the introduction of machinery for their performance at defiance. First amongst these we must rank file-cutting, which is still, as it has been for centuries, almost wholly conducted by hand labour, although the advantages to be derived by the substitution of steam machinery instead are so obvious and important, that the greatest exertions have been made from time to time to introduce such combinations of mechanism as would turn out files of good quality fast enough to reduce their present high price. It would be idle to go into the history of such machines; suffice it to say, that they have one and all failed in some little particular, and that hand labour still reigns supreme in this department of trade.

In spite, however, of all that machine tools have done for us, the consumption of files appears rather to increase than fall off; nor is this much to be wondered at. After all, the fitter's principal tool must be the file. Hand-saws are as useful as they were before the invention of the saw-mill. The navvy requires his pick, the excavating machine notwithstanding; and so will the good old file be needed, while there is an engine to fit up, a clock or a spinning mill to construct.

It is not without some interest, then, that we have read a report in one of the Birmingham papers *(The Post)*, which states that some very successful experiments have been undertaken and carried out there with Bernot's file-cutting machine, which is already in successful operation in many parts of France. As the subject is one of much importance, we do not hesitate to present our readers with the following abstract of this report:—

"Some few weeks ago we announced that a company had been formed for the purpose of making files by machinery, and that, owing to the refusal of the trades' unions of Sheffield—the seat of the file manufacture—to have machinery there, the first works of the new company were to be erected in Birmingham. We further stated that while the patents of Mr. Greenwood, of Leeds, were to be brought into requisition for the making of files in blank, that of M. Bernot, which has been in use some time both in France and Belgium, was to be used for the cutting, the most important and hitherto the most difficult branch of the manufacture. The value of M. Bernot's patent file-cutting machine, we remarked, consisted in this:—That while it would do the work of six or seven men, it only required a comparatively unskilled workman to manage it, whereas the hand file-cutter is a highly skilled workman, commanding a proportionately high rate of wages. It was also hinted that the files cut by this machine were superior in quality to those cut by hand; but this is a question which practical men would no doubt like to decide for themselves. They now have the opportunity. Since we last wrote on this subject, Mr. Allinson, who was engaged by the promoters of the company to report on the manufacture, has brought one of M. Bernot's machines—that shown at the Exhibition of 1862—down to Birmingham, and, by the permission of Messrs. W. May and Co., has put it up in their works, in Tennant-street. The machine, which is very compact, resembles a steam hammer in its general appearance, and the principal features which give it value may be shortly summed up as follows:—It is provided with a vertical slide carrying a chisel on the lower end. The top of this slide is pressed by a flat spring, which is governed by a cam mounted upon a shaft and actuated by a ratchet wheel and 'paul,' and thus the strength of the blow of the chisel is regulated to the varying breadth of the file. A projection at the other end of the slide comes in contact with a cam upon the driving shaft of the machine, and so sets the machine in motion. The blank to be cut is placed upon a travelling slide, which rests upon a semicircular bed, which is mounted in trunnions, resting in swivelling journals, so that the surface of the blank can be presented at the desired angle to the chisel. The blank is held parallel to the edge of the chisel by means of a weighted 'leveller.' All being ready, the file is fixed in the bed, the machine is set in motion, there is a terrible clatter for a moment or two, and the file runs out cut ready, after being hardened, for use. The rate at which the chisel goes may be judged from the fact, that it makes from 800 to 1,500 cuts per minute, and will produce about five or six times the amount of work which can be supplied by hand-cutting. It can cut files of every shape and description that can be cut by hand, and the work is produced with mathematical accuracy. The teeth raised are equidistant one from another, and of that uniform depth and sharpness that forms one of the chief constituents of a good file. This regularity gives evenness, and causes each tooth, when the file is brought into use, to do its proportionate share of the work, effecting thereby a more rapid reduction of the metal acted upon. The teeth, it is said, are not so liable to be broken out, as in hand-made files, where they project one beyond the other, and for which reasons the machine-cut files are found to be more durable. Rasps can also be cut by a suitable adaptation of the machine. This cutting machine has been in practical operation for several years at Douai, in France, and also in Belgium, where, we understand, the superior quality of the files has obtained preference in the arsenals, railways, and machinists' shops of both countries. They have also, we believe, been subjected in this country to severe trials, and have been found of excellent quality. 'The experience at Douai of the cost of working the machines is,' says Mr. Allinson, 'that two skilled mechanics will keep sixty cutting machines in thorough order, and that two persons properly acquainted with the work will make, repair, grind, and whet all the chisels required in working that number of machines. The cost of zinc for file beds is equal to about 3d. per machine per day—the cost of steel for chisels may be assumed, at the outside, at 6d. per machine per day. It is found at Douai that chisels for machine cutting last much longer than for hand, and will effectually cut more files without being re-ground. This arises from the fine edge of the chisel being rubbed a short distance along the surface of the blank to guide the hand cutter; whereas, in machine cutting, the chisel is drawn out of the cut without abrasion. The consumption of oil, and other small stores, are estimated to be the same per machine as in machinists' shops. The machines employed at Douai are of three sizes; but the experience they have now had, shows that the variety of sizes may be beneficially increased. To obtain the advantage of organization arising from a careful division of labour, file manufacturing should be on such a scale as would permit one description and size of work to be confined to one machine and one man, whose constant practice in this one operation would produce a file of a quality superior to anything under the present system of manufacture, and at the same time at a fraction of the cost.' From this it will be seen that Mr. Allinson contemplates carrying out the manufacture on the factory system.

"Mr. Allinson goes on to show the commercial advantages of the machine over manual labour:—'A machine (he says) to cut 14 in. hand bastard files makes 1,000 cuts per minute, or 600,000 cuts per day. A good file-cutter upon the same size and description makes 140 cuts per minute, or 84,000 per day. The machine works as rapidly and perfectly at the end as at the beginning of the day. The man's ability to sustain his rate along with good work is materially affected by fatigue and the relaxation of the muscles consequent on such heavy and continuous labour. At Douai, the machine cut twelve dozen of such files per day. A man cannot cut by hand more than two dozen per day and maintain this average rate for a week. The wages for the week's work of hand cutting would be 44s. The cost of labour and superintendence for the machines would be less than this, but assuming it to be the same, the following is the result of a comparison of the two:—By hand, 12 dozen of files are cut at a cost in labour of 44s. By machine, 72 dozen, or six times the quantity, at a similar cost in labour of 44s. The machine possesses advantages in producing fine cut files even more considerable than shown by the coarse cut just mentioned.' The basis upon which these calculations are made seem to be the actual results at Douai, and the price lists of the File Cutters' Union at Sheffield. In ascertaining the cost of making by hand, however, a discount, varying from 12½ to 20 per cent., is taken off the list price, as allowances are now made therefrom in exceptional cases to such makers of common files as are willing to employ inferior hands, and a liberal rate of wages is charged for working the machines. The actual results of the working of the machine now in Birmingham seem to be these—the youth of whom we have spoken receives 16s. per week, and can cut 12 dozen files per day, the machine, however, running at only 600 or 700 cuts per minute. A hand file-cutter could not cut these same twelve dozen files in less than a week, and would receive from 40s. to 45s. for doing it. The youth receiving 2s. 8d. per day, therefore, does the work for which the man would receive from 40s. to 45s. The whole cost of the machine for the day's work is 3s. 4d." We may observe that some of the files cut by this machine now lie before us, which we can safely pronounce as the best machine-cut files we have ever seen.

THE LONDON ASSOCIATION OF FOREMEN ENGINEERS.

THE July meeting of the above-named Society took place on the evening of Saturday, the 4th inst., at St. Swithin's-lane, City. Mr. Joseph Newton, President, occupied the chair. A very large attendance of members indicated the increasing interest which is felt in the proceedings

of the associated foremen. Several gentlemen were elected as ordinary or honorary associates, and among the latter was the Hon. Mr. Duncan, son of the Earl of Camperdown, and who is studying mechanical engineering under Maudslay, Field, and Sons. After the routine duties had been performed, the Chairman called upon Mr. Muir, of Woolwich Arsenal, and Vice-President to the Association, to read the promised Paper on "Forgings in Iron." That gentleman proceeded to comply, and after some preliminary observations said that the primary condition for obtaining a good forging, whether from under the tilt or the steam hammer, was, undoubtedly, the employment of good material.

In fagotting from slabs it should also be a rule to place invariably the thinnest slabs in the heart of the fagot, so as to ensure that the heat applied should permeate the whole mass equally. The proper construction of the furnace was another consideration of much moment, as was the employment of a skilful furnace-man. So great was the diversity of forging, both with regard to size and purpose, that it would be impossible to refer to each kind. It was only possible in a brief Paper to mention some of the most important, and they in this case would be those which seem of the most difficult character, and which required the greatest amount of care and caution in their production. Such forgings as were to have collars and projections were among the class named. In these it was of the highest importance to take down sufficient "stuff" to allow for finishing off, and to make sure that the projections were in their proper places. If the space between the collars were too little, the chances were that, in drawing out, the forging would become too small to turn up to the right size. If the space were too great, it involved the necessity of "upsetting" or staving up, and the grain of the iron was thus deranged and the forging would be consequently weakened.

It was a well-known fact that heavy shafts—for example, propeller shafts—which have to be coupled by means of large collars or flanges, are very difficult to forge soundly. Not unfrequently the collars were, after great care had been taken, found to be so hollow that a two-foot rule might be concealed in the central cavity. He (Mr. Muir) objected to having those collars rounded in forging, although he could find few who agreed with his views. It was far better, he believed, to forge the collars or flanges of such shafts as those he had referred to square, and to round them up afterwards. It was his impression that solidity would be found to result from this process in almost all cases; for if a proper heat were taken upon the work, it was next to impossible for a square forging to be made hollow. On the contrary, a circular forging could scarcely be made solid. The advantage arising from the mode of procedure he had indicated were, he thought, undeniable; the objection to it was its extra cost.

In one remarkable instance he had been permitted to forge a propeller shaft with a square flange. At four heats the four corners of the square were taken off, the flange was rounded up, and the work proved, as he had anticipated, a great success. He entertained, moreover, a very strong opinion that the great difficulty which had been experienced in obtaining a sound malleable iron gun might be overcome by first forging it in the square instead of the round form. There were many reasons for supposing—and, indeed, he might say that he knew—that many an important forging had been lost, or at least was sadly deteriorated, by the fagot having been composed of different kinds of iron; say, for example, hard and soft. In this case, there would be a natural resistance to amalgamation. Great care and practical judgement, therefore, were required in assorting the irons to be employed for particular forgings, and in putting them into classes in accordance with the special purpose to be served.

He would also recommend that, in any forging requiring taking down, well-rounded setts should be employed, so as to leave always a gusset or fillet, which would save the grain of the iron, and could easily be turned off afterwards if required. It was desirable, also, to put the last wrought heat into the furnace, after it has been worked either by planishing or swaging, and thus bringing it a low red-heat. This was a kind of annealing process which equalized the consistency of the surface. Besides, if one part of the latter had happened to get a larger share of hammering than another, the forging would, while undergoing this ordeal, manifest a tendency to bend, and this would be the fitting time to straighten it. Whatever the nature of the piece of work in hand, only so much of it should be made hot, or at least be brought to a welding heat, as can be at the same time operated upon. The parts submitted to unnecessary heatings will crystaltze, and, as a matter of course, become weak or brittle. In piecing or lengthening shafts, or large forgings of any kind, Mr. Muir recommended that when lays were used for the purpose, the scarfs of those lays should be left tolerably thick at the points. If they are thinned too much, the air acts upon them when drawn from the furnace, and they are sure to be too cold before reaching the anvil. The consequence will be disastrous if this contingency arise. You must then take another heat, without the certainty of being better off next time. It may become a sound union, but will it stand up to the required fire? As has been said, it is desirable in all cases to have the scarfs of the lays of a proper thickness to avoid these evils.

With regard to furnaces, Mr. Muir entered into some interesting particulars, for which we have not space, but he remarked that, when the work to be done was never likely to exceed a foot in thickness, he should suggest the following as proper proportions for the furnace:—3 ft. wide, and 22 in. high. At the doorway the fire-grate would thus be 3 ft. by 3 ft. The neck or flues should be 20 in. deep, and 14 in. wide. The chimney-stack should be at least 36 ft. in height, and the orifice 18 in. in diameter. The reader of the Paper was rather disposed to invert the rule with regard to the taper usually given to the inside of furnace chimneys; he would have them wider at the top than at the base. He prophesied that, if such a plan were adopted, there would be fewer complaints in reference to defective draught.

Mr. Muir proceeded to remark upon the desirability of employing workmen who had theoretically and practically a knowledge of the material with which they had to deal, and of paying them in proportion to their merits.

A discussion followed, which was of an eminently practical character. Mr. Onbridge complained that the vital question of the quality and kinds of fuel to be used in the preparation of forgings had not been touched upon.

Mr. Ives thought that further information might have been given as to the making up of forgings, the proper lay of the grain, so as to combine tightness with strength, &c.

Mr. Gray made some remarks of a similar tendency.

Mr. Stanley, in reference to a statement made by the reader of the Paper, as to the superior strength of beams which tapered from the centre instead of being parallel, thought that such beams should not have a straight, but a curved, or parabolically curved, taper, in order to give the maximum of strength.

Mr. Seccomb was much more ready to undertake a forging than to talk about it. He entered, however, into some practical details in reference to forgings, which demonstrated his capability for both talking and working.

Mr. Stabho spoke at some length, and though approving of what Mr. Muir had said, pointed out numerous items of interest in relation to the subject which had been left unnoticed.

The Chairman must admit that he, too, felt a little disappointed with the Paper. So far as it had gone, it was all very well, but it had not gone far enough. It was to be hoped that Mr. Muir would take an early opportunity of supplementing his work, and that other members of the Association, who were so well qualified to enlighten and instruct them, would assist in the task. A more appropriate subject it would be difficult to find for the consideration of that Society, and it ought to be treated of in all its varied points. He was not without hope that the question of "Forgings in Iron" would ere long be re-opened in that room. Mr. Newton further suggested that the claims of the Messrs. James to the founding of the railway system, as opposed to those of the Stephensons, formed a legitimate and proper field of inquiry for the Foremen Engineers, whose object was to elicit truth and maintain it. At their next meeting, Mr. Stanley and Mr. Humes would read Papers—the one on the "Slide Link Motion," and the other on the "Construction of Locks."

The meeting then separated.

MR. MALLET AND MR. GLADSTONE.

DURING the debate on the Exhibition building, in the House of Commons, Mr. Gladstone, in rather bitter accents, assailed Mr. Robert Mallet, who had been so conspicuously referred to by Mr. Gregory on a preceding evening as an authority on the stability of the building. Mr. Gladstone did not raise himself in the estimation of his hearers by sneering at Mr. Mallet's obscurity. Mr. Mallet bears an honoured name in the scientific world, not only as a writer on earthquakes but as an authority on gunnery and mechanical and civil engineering; and it reflected but little credit on Mr. Gladstone when he confessed that Mr. Mallet's name was new to him. Mr. Gladstone endeavoured to cast ridicule on Mr. Mallet by saying that he was author of the monster gun which was a monster failure. Mr. Bernal Osborne interjected a sentence to the effect that Lord Palmerston was the author of the monster gun. Later in the debate, Mr. Gregory stated that the monster gun was always known by the "Palmerston gun." Mr. Mallet has written a letter to the *Times*, in which he candidly says that Lord Palmerston in 1854 desired the War Department to have the 36-inch mortars constructed. In this he was sustained by the late Prince Albert; but for the merits or demerits of these mortars, in design and construction, Mr. Mallet says that he alone is responsible. He also says that if Mr. Gladstone or any one else will move for the production of the whole of the correspondence, it will be seen that the mortars have been "monumentalized" at Woolwich, through no fault of Lord Palmerston or of himself. We will not enter into the greater question of the capabilities of the Exhibition building any more than to say that we believe that the House of Commons acted in harmony with public opinion and common sense in rejecting the vote proposed by the Chancellor of the Exchequer for buying the building. Had the building been bought and decorated at the public expense, it would have been nothing more or less than a huge job.

BLUMBERG'S GLASS TILES.

MR. F. BLUMBERG, of Cannon-street West, has just patented an improved method of producing glass paving, tiles, or slabs, having therein or thereon suitable designs. The glass when in a molten state is run, in suitable quantities, into a pan mould, made of some material capable of bearing a high polish, and free from all irregularities; a plunger having a design upon it is caused to press upon the glass in the pan mould, and in its upper surface a counterpart of the design. When the slab is sufficiently cool it is removed to an annealing furnace, where it remains until fit to receive colour. The colour or colours may be applied in any manner, or the design may be painted on paper, or other material, placed on the indented design, and secured in position, filling up the cavity with plaster of Paris, or other suitable material. If the tiles are intended among other uses to be laid as paving for halls and other places, the pan mould is so indented that it shall leave small raised projections or points to roughen the face of the glass, and serve to give foothold.

ABSTRACT OF OFFICIAL REPORT ON THE TRIAL OF STEAM FIRE-ENGINES AT SYDENHAM, ON JULY 1, 2, & 3.

LARGE CLASS CONSISTING OF THE FOLLOWING ENGINES:—

	ton.	cwt.	qr.	lb.
MERRYWEATHER	2	18	0	8
EASTON and AMOS	2	18	3	12
SHAND and MASON	2	17	1	0
J. BUTT and Co.	2	14	0	4
NICHOLS (Manhattan)	2	10	1	4
ROBERTS	1	19	1	4
GRAY and Co.	1	18	1	4

FIRST TRIAL.

Delivering 1,000 *gallons into a tank at a true distance of* 67 *ft. and* 27 *deg. from the horizon. The water in the boiler being cold when the signal was given to commence, each Engine commencing to work on attaining a steam pressure of* 100 *lb. on the square inch.*

No.	Names.	Time of raising steam to 100 lb.	Time of filling tank.	Total.	Remarks.	No.	Name.	Time of raising steam to 100 lb.	Time of filling tank.	Total.	Remarks.
		min. sec.	min. sec.	min. sec.				min. sec.	min. sec.	min. sec.	
1	Easton and Amos...	13 14	6 16	19 30		3	Shand and Mason	10 51	12 19	23 10	Suction pipe choked, left off working about 2 minutes.
2	Merryweather	10 25	9 42	20 7	Began to work at 100 lb., fell directly to 40 lb., and continued so throughout, stopped, and steam rose to 130 lb.	4	Butt and Co...	16 30	6 48	23 18	
						5	Roberts	11 40	20 24	32 4	

SECOND TRIAL.

Delivering 1,000 *gallons into tank at same distance, commencing with full steam.*

Legal Intelligence.

COURT OF QUEEN'S BENCH, Guildhall, July 8.

(Sittings at Nisi Prius, before the Lord Chief Justice and a Special Jury.)

SAXBY V. STEVENS.

This, although a patent case, was one of singular interest, and may be said, indeed, indirectly to involve the interests of human life itself, the object of the alleged invention being to prevent or diminish the danger of those accidents on railways which cause too frequently such terrible loss of human life. Every one is aware that these accidents arise most often from the mistakes of signalmen or pointsmen; and most persons who have travelled by rail have had at times their attention directed to the peculiar system of signals and points, with many-coloured signal-lamps and the arms of semaphore signals; and, perhaps, now and then, have had a dim idea, when they saw a train stopped, shunted, or shifted, of the immense importance of all this apparently complicated system, and the awful results which might follow on any casual disarrangements of the apparatus; and perhaps, may have had their apprehensions verified next morning by an account of some fearful catastrophe arising from some such cause. It will not be wondered at that mechanical ingenuity should have been tasked to the utmost to avoid these dangers, and preclude the possibility of disarrangement in the signal apparatus; and the plaintiff had taken out a series of patents, beginning in 1854, with a view of securing this great object. The gist of his alleged invention, perhaps, may be thus shortly summed up—the connecting the signals and points by one and the same movement, and that a self-acting movement, caused by the passage of the train itself. The idea, it will be seen, at once is simple and effectual if capable of being carried out; and the degrees in which it had been carried out and invented by the plaintiff was the question now in litigation. In 1856 the plaintiff, describing himself as of "Brighton, Sussex," took out a patent for an invention of a "mode of working simultaneously the points and signals of railways at junctions to prevent accidents," describing his invention as follows:—

"This invention consists of an arrangement of mechanism by which the switches or points, the signal lamps, and the arms of semaphore signals, as used on railways, may be simultaneously actuated by one movement, and in such a manner that the points cannot be wrong when the signals are right, nor the signals wrong when the points are right. Hitherto the signal lamps and the arms of the semaphore signal or telegraph, have been actuated by one movement of the hand of the signalman, while by an arrangement of stirrups for the feet, he was enabled to adjust the points; but this arrangement has led to serious accidents, from want of proper connection between the points, which shift the carriage from one line to another, and the signals which indicate to incoming trains the safety of proceeding, for while the signals have been right the points or switches have been wrong, or *vice versa*, causing collisions and other accidents. By the simultaneous action of my arrangement much greater certainty and safety are attained; and the use of pedals or stirrups for the feet of the signalman are dispensed with."

And the nature and importance of the invention was more particularly described as follows:—

"This invention consists of certain mechanical arrangements, whereby the danger hitherto resulting from the points and signals being actuated by different persons, or by a motion of the feet as well as the hands of the signalman, is avoided. In many instances accidents upon railways have occurred through the negligence or even the absence of the man to whom the charge of the points has been intrusted in such cases—although the signals may be right, and indicate to the engine-driver that the line is clear, in consequence of the points not being properly set, the train will be either directed upon a wrong line or into a siding, and an accident occur before the driver is aware that his train has gone wrong. In the signal apparatus now in use upon some lines of railway the semaphore signals or signal lamps are actuated by a stirrup put in motion by the foot of the signalman, while with his hand he actuates a lever which sets the points. The danger of this arrangement is, that should the attention of the signalman be required to more than one train, as is frequently the case, while setting the signals for both he may forget the points, and an accident arise from that cause. And by the present invention the semaphore signals, the coloured lamps, and the points, are all actuated by the single motion of a lever, thus rendering the duties of the signalman of the most simple character, and thus making it impossible for an accident to arise from the signals and the points differing." Reverting to the history of the case, it may suffice to state that in 1858 the plaintiff took out another patent for improvements in his invention, the object being an apparatus for self-acting distant signals on railway lines to lock simultaneously the signals at the junctions, or main and branch lines, and especially to secure this result—that when the main line distant signal is set to "all right," it shall by a self-acting movement "lock the levers," so as to prevent them from being moved; and in 1860 he took out another and final patent for apparatus perfecting his invention. In the same year a gentleman named Chambers took out a patent to secure the same object, but its nature and the distinction, if any, between his invention and that of the plaintiff, involve chemical details into which we cannot enter. It appeared that in 1859 the defendant had been employed to effect the object at the Willesden junction of the London and North-Western line, where the Government inspector insisted that there should be some signal arrangement comprising the "locking apparatus," under which, when the signal was "all right," the levers should be locked and held fast, so as to prevent the "points" from being moved. In 1860, the plaintiff was employed at the Victoria Station with the same object, and there, it was said, perfected and worked out his invention. The defendant had since then erected some apparatus with the same object at various stations—Strood, Yeovil, Welwyn, &c., and these were alleged to be infringements on the plaintiff's patent. Such was the cause which now came on for trial before a jury of London merchants; and it will be seen, it illustrated in a striking manner the manifest inaptitude of such a tribunal for the trial of a case involving the most intricate and perplexing mechanical details.

Mr. Bovill, Q.C., Mr. Hindmarch, Q.C., Mr. Macrory, and Mr. Talfourd Salter appeared for the plaintiff; Mr. Grove, Q.C., Mr. Goodeve, Mr. Keane, and Mr. Bridgman were for the defendant.

The floor of the court was occupied by large

models exhibiting a line of railway with a junction station and all the signal posts and lamps, and the apparatus of points and levers, most admirably and ingeniously—but, to the uninitiated, unintelligibly—represented.

Mr. Bovill, in opening the case for the plaintiff, entered most zealously and elaborately into the explanations of all the mechanical details of the models, further illustrated by the aid of photographic drawings in the hands of the jury. For an hour and a half the learned counsel laboured away with unflagging energy to make the jury understand, but as he went on it was lamentably apparent that the more he laboured to make them understand, the less they understood, or were likely to understand, and that indeed, as he proceeded, and the case became more and more involved in intricate details, they became more and more hopelessly bewildered. At last, as the learned counsel was entering in the most lively mannner on a new feature of the invention,

The Lord Chief Justice, in mercy to the jury and the parties, remarked that if it was necessary to enter into all these details it certainly would be useless, for it would be impossible that the jury should understand them and carry them all in their heads.

Mr. Bovill said he had himself felt this difficulty; but then it was of course necessary, if the jury were to try the case, to endeavour to make it intelligible to them, and with that view these mechanical details were essential. And accordingly, away went the learned counsel again, plunging into details more and more intricate and involved, all about "cogs," and "levers," and "bars," and "nuts;" and at last, when he came to explain the alleged invention of Mr. Chambers and the distinction between it and that of the plaintiff, calling for a new set of models,

The Lord Chief Justice again interposed, and said,—Surely, if a case were needed to give the *coup de grace* to our present system of trying these patent cases before a jury, this case must suffice for that purpose. If the jury were a body of engineers and mechanicians, it might be possible that they should understand it; but as it is, it is hopeless.

Mr. Bovill repeated that he quite felt the difficulty, and even if he himself, after long and laborious study, had found the greatest difficulty in understanding it, he could not help despairing of the jury being able to do so. Still, there they were, and all he could do was to do the best he could; and so, once more, the learned counsel set to work and went on a little longer, when

The Lord Chief Justice again interposed, and said,—Would it not be better at once to refer the case to some persons skilled in patents?

Mr. Bovill.—No doubt, my Lord, it would be infinitely better to do so.

Mr. Grove quite concurred, and assured his Lordship and the jury that they had not half got to the end, and that there were a great many more "points." (A laugh.)

The Lord Chief Justice said both the learned counsel must be well aware that after many hours or days of wearying labour on the part of the jury it would really be a "toss up" which way the verdict should be; and this was hardly a satisfactory result either to these suitors or all the other suitors of the court. If the case went on it would take up the rest of the sittings, and after all end most unsatisfactorily—probably by an adjournment till next November.

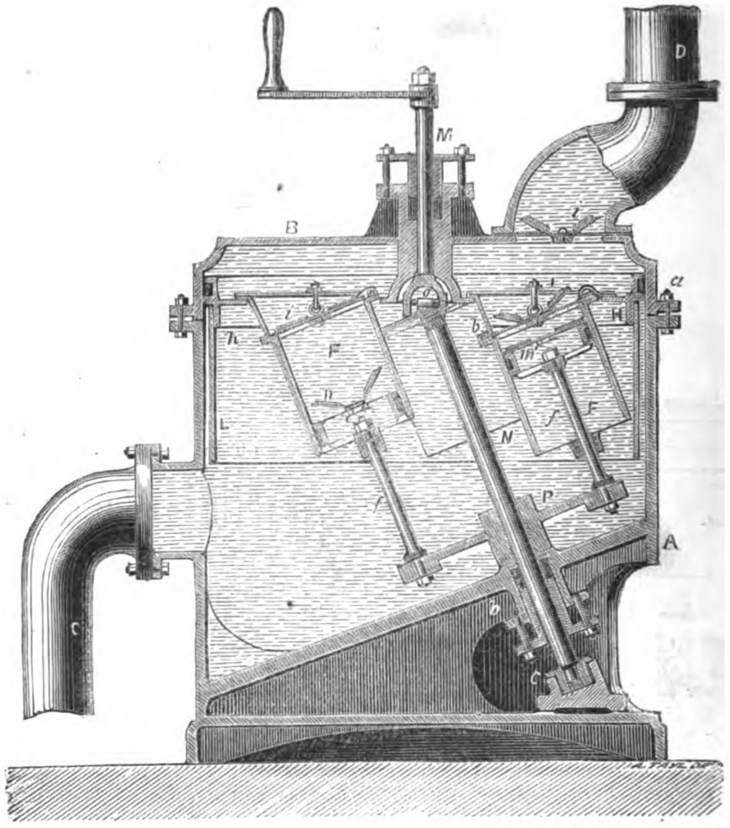
Mr. Bovill said that was no doubt true, and even in the hands of an experienced and skilled referee these patent causes took up many days, and even weeks.

The Lord Chief Justice observed that in the hands of such gentlemen, well skilled in such subjects, and acquainted with such cases, the case would at least end satisfactorily, in a decision in which both parties had confidence; whereas the present mode of trial was really hopeless.

The learned counsel on both sides cordially concurred in that view, and, after consulting with their clients, agreed to refer the case to Mr. Montague Smith, Q.C.

The Lord Chief Justice then dismissed the jury, to their manifest satisfaction.

METIVIER'S PUMP.



METIVIER'S PUMP.

THE following description of this rather novel hydraulic apparatus is extracted from "Le Genie Industriel":—

The mechanism of this pump consists, substantially, of two shafts, inclined under a certain angle to each other, turning in the same direction, and coupled together by a universal joint, the construction of which secures the rotation of both shafts at the same speed.

Upon one of the shafts is fixed a plate, which carries the pump barrels, which are fixed or moveable, according to circumstances; on the other shaft is fixed a plate or cross-bar, on which are mounted the pistons, these last fixed or moveable, according to the arrangement of the pump barrels.

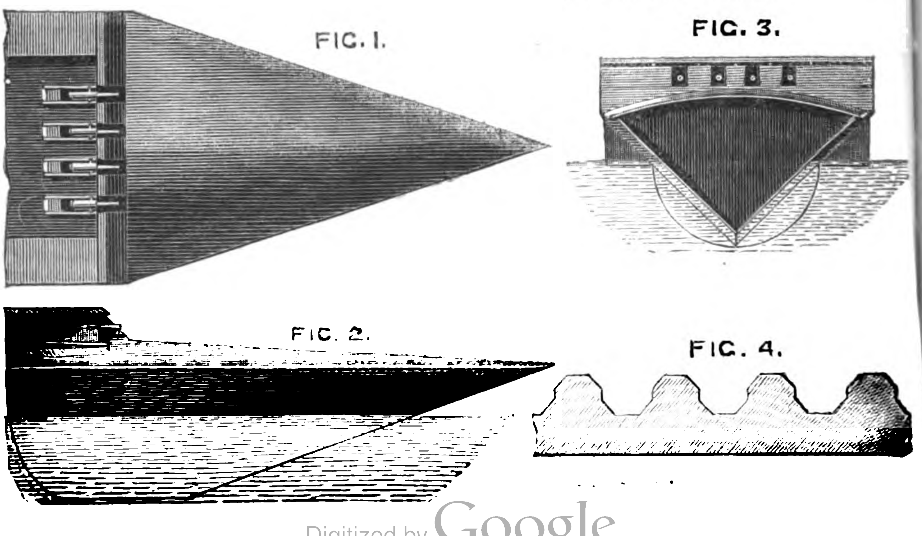
The general construction of this pump will be easily understood by the accompanying drawing.

The apparatus consists of a metal cylinder or vat (*cuve*), made in two distinct parts, the larger marked A, and the lid B; this last being fixed by means of bolts *a* to the vat B, so that it can easily be removed when the machinery requires examination. This vat is fitted with a suction pipe C, and the lid is supplied with the stand or forcing pipe D, each pipe being fitted with a double click valve.

A plate H is fixed on the shaft M, to which the power is communicated, and is fitted with a metallic or hemp packing round its edge, so that it revolves water-tight within the external cylinder A. The shaft M passes through a stuffing box, which is fitted in the cover, and is connected at the lower end with the shaft N, by means of the universal joint *o*. These two shafts form between them a certain angle, and passing through a second stuffing-box, the lower end is supported by and revolves in a foot-step *c*.

To the first plate H are hinged (*relies*) the four pump barrels F, moveable round the bolts I in order that they may accommodate themselves to the angles of their piston rods. Elastic rings are fixed to the upper part of the pumps, in such

CAPTAIN WHEATLEY'S SHIPS OF WAR AND ARMOUR PLATES.



LONGLEY'S BRICK-MAKING MACHINE.

FIG. 1. FIG. 3. FIG. 2.

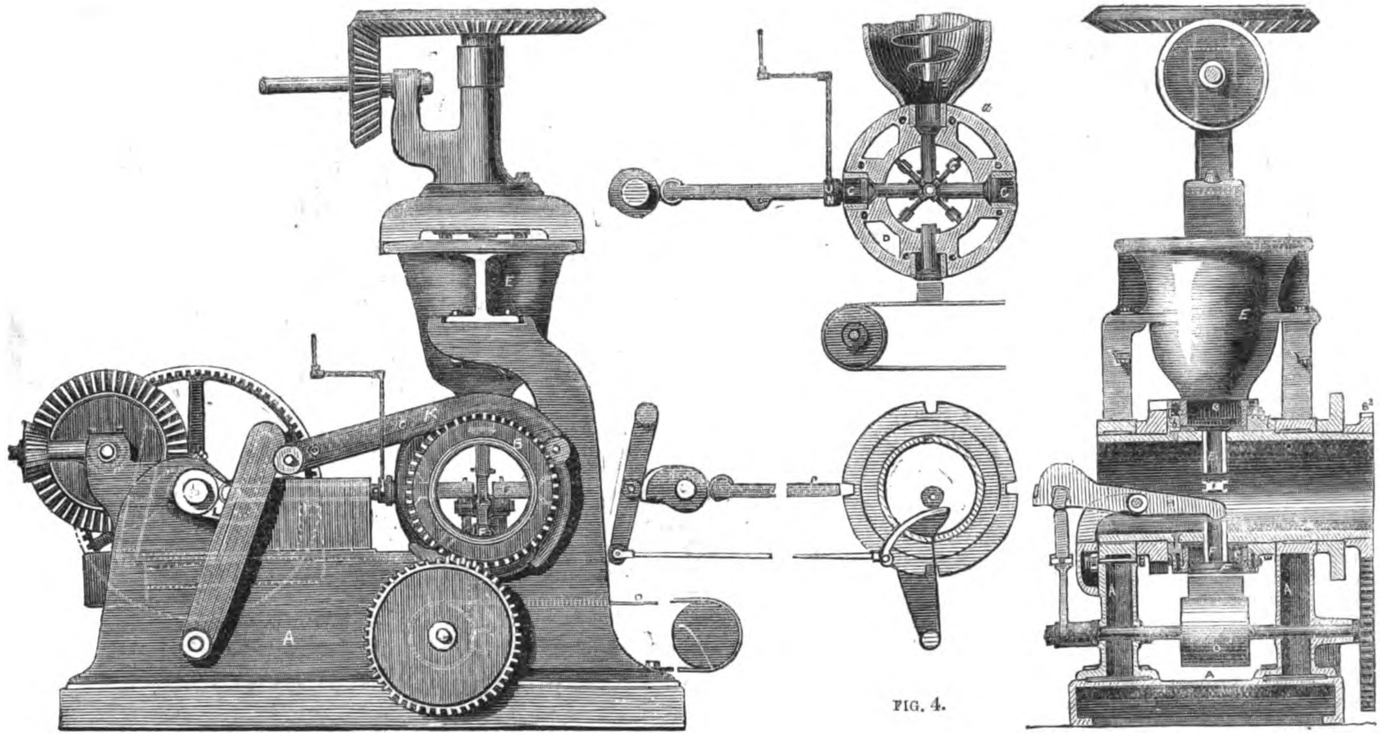


FIG. 4.

a manner that they can only communicate with the space within the lid B through the valves *i*. On the lid is fixed the forcing pipe D. On the inclined shaft N is keyed the cross-bar R, to which are fixed the rods *f* of the four pistons M, which are fitted with valves *n*. The rods *f* are disposed parallel to, and at equal distances from, the shaft M.

The mode of operation is as follows:—By causing the shaft M to perform half a revolution, the same movement is communicated to the shaft N. Now, if we only regard the action of one of the pumps, we find that, in making this semi-revolution, the piston is compelled to travel from one end of the pump to the other, owing to the angle of inclination of the shaft N. The piston, of course, draws an amount of water from the interior of the vessel corresponding to the size of the barrel. In again making another half revolution, the barrel of the pump and its piston return to their first position, forcing the water, in doing so, from the pump into the lid.

The same result is produced during a complete revolution by each pump, alternately drawing and forcing a volume of water proportionate to the diameter of the pistons and the length of their stroke.

CAPTAIN WHEATLEY'S SHIPS OF WAR AND ARMOUR PLATES.

CAPTAIN J. WHEATLEY, of the Royal Navy, has just patented some improvements in the construction of ships of war. He proposes to form the bow of the ship with a sharp projecting grab or crab bow at an angle of about 25 deg. with the keel, and propel the vessel by paddle wheels and screw, or by screws, the wheels when used working independently, so as to steer the vessel thereby. The rudder is to be supported by chocks, acting like a common vice; and in order to be able to mount guns of large calibre and power (say, thirteen inches and twenty tons weight, smooth bore) in or near the centre of the vessel, pointing in a line with the keel, to construct a glacis plated over with armour plates, and over the whole fore part of the vessel, and extending to the front of the paddle boxes. The engravings clearly show how the invention is to be carried out.

Fig. 1 is a plan; fig. 2, a side view partly in section; and fig. 3 a transverse section taken at the line 1, 1, of the fore part of a war vessel, adapted to be propelled by paddle wheels, acting either in conjunction with a screw or screws or otherwise. It will be seen that the guns are placed a little forward of the centre of the vessel, where a casemated battery is formed, rendered shot-proof by armour plates. The guns are mounted on slides, so as to fire through embrasures; they are placed parallel the one to the other, and have no power of training the guns, being laid on to the mark by the steerage of the ship. The form given to the fore part of the ship will cause it on running into another vessel to rise on striking the blow, and then the weight of the ship tends to force under the adverse vessel, and will do so if the blow be struck with sufficient power. The armour-plated glacis will deflect off any shots which may strike it, and will, in most cases, throw them up clear of the battery, as before-mentioned. Two screw chocks are employed, one on each side of the rudder; these being screwed will nip or hold the rudder in a central position, or will support it in any desired position, the chocks being more or less screwed up as may be required.

The second part of the invention consists in a mode of manufacturing armour plates, for which purpose the armour plates are to be rolled or formed with external parallel projecting ribs or latticework, as illustrated in fig. 4, at a distance apart less than the diameter of a shot or projectile which would be thrown against a ship, fort, or battery protected or coated with armour plates, with the knowledge that the same would pass through the plating if of the ordinary construction. As a general rule, it will be found that balls or other projectiles less than four inches diameter cannot be used with effect against armour plates such as are now employed, and therefore if the parallel projecting ribs or latticework have a minimum space between them of less than four inches when using a like quantity of iron in each square foot of the plating, no shot or other projectile which would be used could enter between two neighbouring ribs or lattice openings, so as to strike the surface of the plate on which the projecting ribs or lattices are formed, without first injuring one or both of two neighbouring ribs. In practice, the thickness of the plates on which the projecting parallel ribs are formed, and the thickness of the plate where the ribs or lattices are situated, may be greatly varied, depending on the quantity of iron to be used in each square foot of the armour plates.

LONGLEY'S BRICK-MAKING MACHINE.

THE above engravings illustrate an invention recently patented by Mr. W. Longley, of Leeds. The invention relates to an arrangement of brick-moulding machinery, whereby bricks are produced from "wet" clay, having great solidity with a smooth exterior, and containing a less amount of moisture than those produced by hand or by machinery at present in use.

Fig. 1 is a side elevation of the machine; fig. 2 is a partial end elevation, showing in longitudinal section the cylinder which carries the moulds, and presents them successively to a conical hopper to be fed with clay; fig. 3 is a cross section of the mould cylinder, showing its connection with the hopper; and fig. 4 shows the means used for locking the cylinder, so as to keep the moulds stationary while being filled and discharged.

A, A, is the main framing of the machine, upon which is mounted in suitable bearings a horizontal cylinder B. This cylinder is cast with open ends, and it is fitted near the middle of its length with a series of four moulds, C, C, arranged radially around it. These moulds are formed by recesses cut through the periphery of a projecting band *a*, *a*, that surrounds the cylinder, having their ends closed by the rings *b*, *b*, (bolted to the cylinder) a series of close chambers D, D, are formed in a similar manner between the moulds for receiving steam for heating the moulds. Immediately above this concentric projection of the cylinder B, and in close proximity thereto, is situate the hopper E, in which a screw is mounted for forcing down the clay into the moulds as they are presented to the hopper. Fitted into the moulds are plungers F, the stems of which project through the inner periphery of the cylinder B, and are intended for discharging the bricks from the moulds; the inner periphery of the cylinder B is also pierced to receive the ends of a cruciform arrangement of steam pipes G (fig. 3) for supplying steam from a central pipe running in the direction of the axis of the cylinder to the chambers D; an intermittent axial motion is given to the cylinder, for the purpose of bringing the moulds severally under the hopper to be filled and subsequently under the action of a

rocking presser lever H, for the discharge of the moulded bricks in the following manner:—To one end of the cylinder (outside the framing A) is keyed a kind of ratchet wheel having four teeth, one of which takes into a stud pin fixed to the extremity of a bent arm K, which arm is jointed to a rock lever having its fulcrum on a stud projecting from the side framing. A bowle on this arm K rolls over a track formed by the boss of a cog wheel B^2 (hereafter to be referred to), and thus the smooth working of the ratchet movement in ensured. In the inner face of the lever, a longitudinal recess is cast to receive a guide pin projecting from a crank arm L on a transverse cam shaft, which turns in suitable bearings in the main framing. To the opposite end of this shaft is keyed a cog wheel with internal teeth, into which gears a pinion on the boss of a bevel wheel M, mounted on a stud axle, carried by the ain framing. This wheel M is driven by a bevel pinion, which receives its motion from any prime mover. It will now be understood that for every rotation of the cam shaft, the arm K will be caused to pull round the cylinder B one-fourth of a revolution, and then move forward to bring its stud pin in front of another ratchet tooth. When the uppermost mould C has been filled by the driving down of clay from the hopper E, through the rotation of the propelling screw, this axial motion of the cylinder takes place, and at that moment a knife edge situate at the bottom of the hopper scrapes the lips of the mould clear of clay. The mould is now brought down opposite a horizontal plunger N, and by it the clay is compressed in the mould. The rod of this plunger N slides in a fixed guide, and it is fitted with a bowle which is kept in contact with a cam on the cam shaft by means of a weighted crank lever, with which the plunger rod is connected. As the increasing radius of this cam presses on the bowle, the plunger will be forced forward into the mould presented to it, and compress the clay contained therein. When this is effected, and the cam in its revolution has passed out of action, the weighted crank lever will draw back the plunger N out of the mould. Another movement of the cylinder B will now take place, and the compressed brick will be brought down to the position for being discharged on to an endless apron O. This is effected by the stem of the plunger F of the mould being pressed upon at its rear end by the rock lever H. This rock lever is mounted on a bent bracket arm attached to the main framing, and it is provided with a bowle, which bears upon a rocking cam having a stud pin on the framing for its fulcrum. This rocking cam is jointed to a rod, which connects it with a rocking arm, pendent from a bracket on the framing. The arm carries a bowle which bears against a cam on the cam shaft. The revolution therefore of the cam shaft gives a reciprocating motion to the cam H, thereby causing it to rock the lever H, and depress the plunger that has been brought beneath its inner end. This depression of the plunger effects the discharge of the brick, which is facilitated by the heating of the moulds through the admission of steam as before explained. To prevent the adherence of the clay to the compressing plunger, it is made hollow, and steam is conveyed thereto by an arrangement of jointed steam pipes, as shown at fig. 1. The discharged brick is received on to an endless apron, which receives motion from the spur wheel on the cylinder B, gearing into a spur wheel on the axle of one of the carrying rollers of the endless apron O. The cylinder B is also furnished with a ring in the periphery of which are four notches, corresponding with the moulds. These notches (see fig. 4) are for the purpose of receiving the taper end of a locking bar P, which, when it is desired temporarily to lock the cylinder (as at the moment of filling, pressing, and discharging the moulds) is thrust forward by a cam on the cam shaft pressing upon a bowle, mounted on the end of the locking bar which slides in guides provided to receive it. The release of the cylinder is effected by throwing back the locking bar by means of a weighted crank arm, as in the case of the compressing plunger.

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

All communications should be addressed to the EDITOR, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

RECEIVED.—D. H.—A. D.—T. W.—Messrs. E. and T.—T. W.—J. W. and Co.—W. R.—M. and Son.—E. F.—J. H.—J. R. and M. W.—W. W.

D. K.—Next week.

J. W. (Gosport).—We cannot answer legal questions.

T. H.—Neither of the sketches represent the correct form for the arms of a reaction wheel, which should be so curved as to permit the water to flow in a straight line from the centre of the wheel to the delivery orifices. This curve somewhat resembles an involute. The area of tube should gradually decrease from the centre to the orifices of delivery.

W. K. (Canterbury).—We really cannot advise you: we should like to see your demonstration, but we cannot promise to publish or make any use of it.

Correspondence.

COATING BOILERS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—We are working a boiler 16 ft. long by 6 ft. in diameter, heated by two internal flues, and made of 7-16th in. plates. It is set in brickwork, and covered with sand 4½ in. thick, with one course of bricks thereon. The two ends and one side are enclosed by brick walls, and there is a corrugated iron roof about 6 ft. above the crown of the boiler, supported on one side by the wall, and on the other by iron pillars. The left side of the boiler-house is, of course, open. If we remove the coating of brick and sand from the top, the space left exposed will be about 6 ft. Our engine is 12-horse power; average working pressure 30 lb. to 32 lb. per square inch, with a weekly consumption of slack of about 3½ tons.

We fear that slight escapes of steam from faulty rivets will, by keeping the sand wet, damage the plates by corrosion, if we remove the sand, &c., and leave the top of the boiler exposed (retaining the roof, and if necessary enclosing the now open side). Should you calculate that we should incur any loss in power or fuel from condensation of steam; and if so, to what extent would this be?

We know that the more closely a boiler is covered, the more economical it is in point of fuel; and the question we wish to decide is, whether this economy is counterbalanced by any danger to the boiler by the covering we have on it at present; and whether the additional safety procured by being able to examine the plates (if we remove the coating of sand) will be sufficient to compensate for any additional cost of working which may ensue.

Yours respectfully,

ENQUIRERS.

Wolverhampton, July 7.

[If your boiler is properly made and in good order, there should be no escape of steam from the rivets; and in any case, we see no difficulty whatever in removing the sand from time to time for examination. If you leave so much of your boiler exposed, we have no doubt that you will lose heat. Why not use felt and boards? or turn a plain brick arch over the top without any sand.—ED. M. M.]

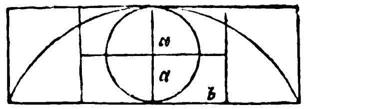
CONSTRUCTION OF A SQUARE EQUAL TO A CIRCLE.

SIR,—I fell upon a pamphlet the other day, which purposes to give to the world a solution of the problem of "squaring the circle" as soon as the author is guaranteed a suitable reward. I do not think I shall damage his prospects of receiving it by pointing out the limits between the possible and the impossible in that problem; which I have not seen done in any mathematical book, though it very likely may have been.

As the area of a circle of radius $a = \pi a^2$, or the radius X half the circumference; and those two things are well known to bear a ratio to each other which is expressible by no finite number of figure in any form, it is evidently impossible either to calculate or to construct a square equal to that circle, without that very quantity π, or the length of the circumference, being contained somewhere in the figures expressing the square. In other words, π can never be eliminated from the result, nor can the square be expressed or constructed by means of any straight lines, derived merely from the radius without actual measurement of the circumference. And this is the sense in which mathematicians rightly deride the attempt to square the circle as an absurdity, if not something more. But it is quite possible to construct by recognized geometrical rules, though by something more than rule and compasses, a square whose area shall be mathematically, and not merely approximately, equal to the area of a given circle.

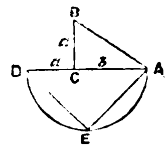
Measuring the length of a circle by a string is hardly a recognized mathematical operation; but the construction of a cycloid is. The base of a cycloid, or the straight line, on which the generating circle rolls while a point in its circumference traces out the cycloid from one point of that straight line to another, is necessarily equal to the circumference of the circle, or $= 2\pi a$.

FIG. 1.



Therefore the rectangle containing the whole cycloid $= 4\pi a^2$; and if the base is divided into four equal parts (b), the rectangle $2ab =$ the area of the circle; and it only remains to construct a square = that rectangle.

FIG. 2.



Draw $AC = b$, and $CB = a$ at right angles to AC; join AB and prolong AC to D, making $CD = a$; then $AD^2 - AB^2 = a^2 + b^2 + 2ab - (a^2 + b^2) = 2ab$.

Draw a semicircle on AD as diameter, and with centre A and radius $AE = AB$ mark off E in the circumference, and join DE. Then E is a right angle and $DE^2 = AD^2 - AB^2 = 2ab =$ the area of the original circle. That is, DE is the side of the required square, or $= a\sqrt{\pi}$.

E. B. DENISON.

33, Queen-Anne-street, July 6.

P.S.—It has nothing to do with this question; but it is remarkable that, in the length of the cycloid itself, π disappears, or may be said to have been rolled out; for the length simply = 4 times the diameter of the generating circle.

A NEW RAILWAY SIGNAL.

SIR,—Will you allow me a space in your widely-circulated journal to correct a paragraph which appeared in your last number, relating to a new railway signal.

On comparing the description, in the paragraph alluded to, I find it identical with the principle of my patent, dated April 10, 1862, of which I enclose you a description, which appeared in the *Brighton Gazette*, August 14, 1862, from which it is obvious that the signal you describe is an imitation; moreover, my patent signal has been working more than twelvemonths at the Lover's-walk Junction, on the London, Brighton, and South Coast Railway, and is mounted on the top of a column, with a dial plate of 4 feet in diameter, and is furnished with a hand which rotates backwards, on the treadle being depressed by the flange of the first wheel of the passing train, after which the hand returns to its former position, thus indicating the number of minutes which have elapsed since the train's passage.

The signal is also illuminated at night to show the red, white, and green, transparent signals, during its performance.

I would not have troubled you with this detail, were it not that your paragraph is not only calcu-

lated to do me an injustice, but to mislead the public as to who is the true inventor.

I am, yours obediently,
EDWARD FUNNELL.

54, East-street, Brighton, July 6, 1863.

INVENTION FOR THE PREVENTION OF COLLISIONS ON RAILWAYS.

Mr. E. Funnell, watch-maker, of this town, has recently patented an entirely new description of self-acting night and day signals for railways, the principal being the indication of time and space between all passing trains, one of which is now and has for some weeks been most satisfactorily tested, at the Lover's-walk Junction, on the Brighton Railway. A model may also be seen at the patentee's, 54, East-street. This invention consists, first, of a cast-iron, hollow pillar, fixed near the left hand side rail, on the top of which is a dial plate, varying from three, four, and five feet in diameter, divided to mark the time of ten minutes on the lower half of the dial—viz., five red spots on the right, indicating danger; and five green spots on the left, indicating caution, or any number of minutes required suitable to the positions in which they are fixed, and is also furnished with an indicator or hand, which rotates from left to right, and from right to left. On the upper portion of the dial is fixed a lens, through which the different colours for night or fog signals are given by the aid of gas or lamp. The mechanism is also fixed to the top of the pillar and back of the dial, which consists of iron framework, two wheels, pendulum, weight, and a quadrant-shaped disc, on which are fixed red and green glasses. A case at the back of the dial encloses the whole of the works; they require no manual attention except oiling once or twice a year. The working of the instrument is produced in the following manner: The first wheel of the passing train depresses a lever placed at the inner side of the left-hand rail, which is communicated to a mechanism by a rod passing up the pillar, and re-winds the weight, rotates the hand backwards to the right side of the dial, parallel across the centre, and replaces the red light for the night-signal simultaneously, both of which indicate danger, and remain locked until the last carriage has passed; after which the pendulum vibrates ten minutes, the hand commences returning to its former position, and, on arriving at the fifth minute discharges the red light, and the green light appears, until the hand has arrived at the tenth minute, by which time the green light will disappear and a bright light remains, with the hand at rest parallel across the left side of the dial until another passing trains repeats its movements, and, should another train pass at any minute during its movements, the hand will return as before described, and also the red light; and, should a train stop at the signal, it will indicate danger during the whole time; or, should a break down occur to a train between the signals, the approach of a train on the up or down line can be stopped by a person pulling a wire, which will make the signals show danger for any length of time required. If the gas be laid all along the lines, the lights of a range of signals can be regulated by station masters, in case of fog or nightfall, and in the morning can be turned down to a small light. The inventor points out the great advantages railway companies will derive by adopting these signals at every mile distance, as it will prove the saving of large sums per year, and also avoid the destruction of life and property.

[The paragraph to which our correspondent alludes was extracted from a Doncaster paper. We regret that through inadvertance we did not quote our authority.—ED. M.M.]

ON INDIAN RIVER STEAMERS.

SIR,—I have read with much interest the article in your valuable journal on the above subject. I gave some attention to the subject in 1860, when I was informed by a gentleman from India that Bourne's train had proved a failure.

Under the peculiar circumstances of Indian river navigation, the same means of obtaining speed as are adopted in deep water cannot be used. Great displacement with very small draught and moderate length are imperative requirements.

Perhaps most of your readers will remember Mr. Scott Russell's remarble experiments with vessels in shallow water. Bearing those experiments in mind, I did not expect that the "Stanley," built by him, would realize the same speed in Indian inland waters that she did in the Thames, and the result proved that I was correct, and tended to corroborate Mr. Scott Russell's own theory. I therefore designed a form of bow which could not be subject to any wave theory, and which I then thought, and still think, would be found to be the best form that could be adopted, and I proceeded to patent it, but, as I received no encouragement from any of the companies, I let the patent drop. The stern of the vessel I proposed to be of the ordinary spoon shape; the body perfectly rectangular; and, of course, the bottom perfectly flat—the flat bottom being continued to the extreme fore end of the stem, where it forms a sharp horizontal cutwater, the upper part of the bow being so formed as to raise the water in a manner very similar to the action of a plough in the soil; the water being lifted and thrown outside by the motion of the vessel. With this form of vessel Mr. Leys' co-efficient of fineness is quite sufficient. My models were shown to several gentlemen from India, well acquainted with the navigation, and highly approved of by them; and the models were finally deposited at Gresham-house, Old Broad-street.

I think that large engines have facilitated the ruin of most Indian river boats. Instead of Mr. Leys' proposed engines, I would use engines of the locomotive class, working at 120 lb. to the square inch, with a piston speed of from 900 to 1,200 ft. per minute; the engine shaft to revolve about three times as fast as the paddle wheels; the engine shaft to have a small wheel fitted gearing into a toothed wheel on the paddle shaft; the exhaust to pass into two surface condensers formed, each of a bundle of tubes right abaft each paddle wheel, so that the spray from the paddle wheels would keep every tube wet; the steam to pass inside the tubes; the tubes to be closed at the outer ends; the condensation to be accomplished *under pressure* if necessary, say at 5 lb. to the inch. With this back pressure to the exhaust, the condenser tubes would give off the surplus heat at 228 degrees very readily, and return the water at boiling point to the boiler; and the back pressure would not be of any great moment when working at 120 lb. in the boiler, and taking into consideration the great importance of supplying. the boiler with distilled water.

The *steering* I would accomplish by a small transverse paddle wheel astern, with a small pair of engines fitted to one crank.

I may add the fact that the above form of bow is well adapted to run into sand banks, so numerous in Indian rivers, and to back out of them easily. The horizontal cutwater will be slightly depressed while running, and will cut its way into a sand bank for a foot or two, when the vessel's motion being stopped the head will rise an inch or two, with a few shovels full of sand upon the bow, and the engines being reversed she will back off at once.

I am, Sir, your very obedient servant,
1, Clifford's-inn, July 6, 1863. T. MOY.

Miscellanea.

Most of the hose employed by the engines at the trial at Sydenham was manufactured by the North British Rubber Company.

The Lords of the Admiralty have abandoned the intention—at least for the presnt—of converting any of the wooden vessels standing on the stocks at Chatham dockyard into iron-clad ships of war.

The *Times*, in commenting on the case of Saxby *v.* Stevens, a report of which will be found in another of our columns, says:—"As we have recently reported a great patent case, Betts *v.* Menzies, which, after being tried three times with contradictory verdicts, and an appeal to the House of Lords on the law, and which, after some five or six years of litigation, has just been sent to a new trial, to recommence a similar costly career of legal inquiry under the system of trial by jury, we may perhaps be permitted to say that our own observation amply confirms that which the learned counsel stated to be the universal opinion of the profession—the utter unfitness of ordinary trial by jury for such cases, and the urgent necessity of some new tribunal for the purpose."

The *Building News*, speaking of the late trial, says:—"We hear that the Americans are not satisfied with the result. They say that a concurrence of circumstances contributed to the temporary failure of their engines, and they have challenged the English makers to meet them in another trial, each competitor to put down £50 or £100. Perhaps, Americans are something like what Napoleon said of Englishmen—they don't know when they are beaten. At all events, we like the pluck of our American cousins, and we hope the challenge will be accepted, and that another trial will soon take place."

A target on the principle of Mr. George Clark, described as consisting of compound dovetailed fastenings and iron cellular backing, was tried at Shoeburyness on Tuesday. The Duke of Somerset, Earl de Grey, and a number of scientific gentlemen were present. The 68-pounders shook some of the bolts and rivets, and two of the shot went through the target, and a salute of four 68-pound shots did further damage. A 150-pound spherical shot, with 50lb. of powder, went clean through the four inches of iron and backing, and cleared away one of the great beams supporting the target. The last shot fired was a 300-pounder steel shell, fired with 35lb. of powder. This went through, between two of the upper plates, lifting the whole of one of the ponderous massive slabs several inches. The general result was not favourable to the principle of construction.

An illustration of the progressive nature of the times has been afforded to the inhabitant of Northampton, during the present week by one of Messrs. Allchin and Son's traction engines steaming through its streets. The engine runs very easily, and can be stopped almost immediately. It is guided by a wheel placed in front of the boiler, the wheel being attached to a chain fixed to the axles, and by this means the engine can be turned from one side of the road to the other as easily as a horse.

A correspondent of the *Sunderland Times* states that the mean level of the sea at Sunderland is 7·50 ft. below what it is at Liverpool. The quay wall at Sunderland is only 8 ft. above high water mark, but the Royal Engineers make it 15·50 ft. above their datum line, which is high-water mark at Liverpool at ordinary spring tides. They were assuming Sunderland sea level to be the same as in the Mersey, and so they calculated the sill of the embarette guns at the battery on Abbs' Head at 69 ft., whereas it is only 61 ft. 3 in. High-water mark at Liverpool is the datum line of the trigonometrical survey all over the North of England, as high water at London is for the South. On the Ordnance Map, substract 7·50 ft. from any given height to get the actual height above high water at Sunderland.

If we have not yet got the best breech loading gun, it certainly is not from want of experiments. An 18-pounder bronze rifled gun, invented by Mr. Broadwell, has been tried at the Royal Arsenal to test the peculiar gas proof principle involved. The arrangement consists of a peculiarly shaped ring permanently located and self-acting, which is placed block, and acts against a bearing in the gun concentric with the bore. The experiments have been eminently successful.

The editor of the *Oil City Register* has recently paid a visit to the wonderfull flowing oil well in that neighbourhood, which throws every vein yet struck entirely into the shade. He says:—While there, the parties owning it were making preeparations to put on a stop-cock, so as to control it. The first joint of tubing was taken off, and the oil spouted up to a height of 50 ft. with a roar like a hurricane. The stream from the pipe, which was 2½ in., was incessant, and we looked at the scene for an hour or more, and finally had to leave before the stop-cock could be put on. We could form no definite estimate of the capacity of the well. Some estimate it as high as 2,000 barrels, some 1,000; but we are satisfied that it was flowing at the rate, when we saw it, of 1,200 to 1,500 per day. The depth of the well is about 450 ft."

Letters from Alexandria of the 24th ult. state that all hopes of immediately repairing the injured link of the Malta and Alexandria cable have been abandoned. Messrs. Canning and De Santy, the representatives of Messrs. Glass, Elliot, and Co., will return at once to England, and Mr. Gibson, Government Inspector, will return to his post at Malta. It was at first inferred that the defect was a mechanical one, and near the shore, if not actually in the harbour at Alexandria. The tests were begun under this impression, but, after a series of careful experiments, the scientific operators were led to change their opinion, and to look for the fault further away, probably close to Benghazi. It is now likely that it will be necessary to obtain the assistance of a steamer from England specially adapted to effect the anticipated repairs, in which case the interruption of telegraphic communication between Alexandria and Benghasi may extend to several months.

An influential and numerous meeting took place on Monday last, at the house of Mr. James M'Connell, C.E., 2, Dean's-yard, Westminster, to consider the system of laying submarine telegraph cables

invented by Captain Jasper Selwyn, R.N. Amongst those present, Lord Shrewsbury, Lord Richard Grosvenor, Sir Edward Belcher, Admiral Duntze, Mr. Henry Danby Seymour, M.P., Mr.W. Gravatt, F.R.S., Mr. Thomas Allan, C.E., Mr. Cornelius Varley, and other well known scientific gentlemen took an active part in the proceedings. Resolutions were passed approving of the principle, and a committee was formed to carry out an experiment with the apparatus.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c.—*none*.
Boilers and Furnaces, 3271.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 3250, 3383, 3278, 3279.
Ships and Boats, including their fittings, 3256, 3258, 3276.
Cultivation of the Soil, including agricultural implements and machines, 3259.
Food and Beverages, including apparatus for preparing food for men and animals, 3273, 3289.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 3265, 3274, 8275, 3282, 3284.
Buildings and Building Materials, 3255, 3272.
Lighting, Heating, and Ventilating, 3245, 3254, 3266.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 3246, 3253, 3257, 3261, 3267, 3268, 3269, 3270, 3286, 3287, 3290.
Metals, including apparatus for their manufacture, 3241, 3262.
Chemistry and Photography, 3247, 3249.
Electrical Apparatus—*none*.
Warfare—*none*.
Letter-Press Printing—3277.
Miscellaneous, 3242, 3243, 3248, 3351, 3252, 3230, 3264, 3280, 3281, 3283, 3285, 3188.

3241. A. T. Becks. *Improvements in machinery for cutting or shearing sheets or plates of metal.* Dated December 3, 1862.

This invention consists in arranging and working a series of rotating cutters in the manner hereinafter explained. Two parallel horizontal shafts, situated the one over the other, are driven by steam or other power by means of a pinion on a driving shaft. The said pinion engages with a toothed wheel on the lower shaft, the said toothed wheel engaging with a similar toothed wheel on the upper shaft. Each of the said shafts carries near the end opposite to that on which the toothed wheel is fixed a circular or rotating cutter. These cutters are fixed on the shafts, and their cutting edges meet and cut one side of the plate or sheet or sheets of metal operated upon. The said shafts are hollow, and in the axis of each a screw is situated. A screw nut or box works on the screw in the interior of each hollow shaft. By turning the said screws by a winch, or otherwise, the screw nuts may be made to travel in one or other direction on the screws. A second circular or rotating cutter, capable of a sliding motion, is situated on each shaft, and is connected with the screw nut or box in the shaft through a slot running nearly from end to end of the shaft. By turning the screws the moveable cutters may be made to approach to or recede from the cutters fixed on the shafts, so as to accommodate the distance between the cutters to the width of the plate or sheet or sheets to be cut or sheared. By passing the plate or sheet or sheets of metal through the machine in a horizontal direction, both their edges or sides are simultaneously cut or sheared parallel. The ends of the plate are cut by means of a fifth cutter forming a pair with the fixed cutter on the upper shaft. *Patent completed.*

3242. R. B. Thomas. *An improved apparatus for turning over the leaves of music.* Dated December 3, 1862.

This invention is carried out in the following manner:—To the desk which supports the music the inventor applies a series of wires, capable of turning on a central pin at top and bottom, one of these wires being employed to turn over each leaf of the music. The pin upon which these wires turn over is placed to the left of the centre of the stand, which is the turning point of the leaves, so that the wires being originally placed behind the centre of the leaves (where they have most power), as the leaves turn over slide outwards on to the margin of the leaf, so as not to obstruct a clear view of the notes. Each of these wires is furnished at its lower outer angle with a small wire hook or projection, behind which the lower margin of the leaf is placed, to obviate the liability which a leaf might occasionally have of turning over with the preceding one, and leaving its own wire bare. Each of the wires is also provided with an india-rubber or other spring, having a constant tendency to throw the wire over to the left. On the right hand side of the lower part of the desk, and close to the position the wires assume when turned over to the right, he places a spring catch or bolt of a peculiar construction. This catch is so formed and arranged that, when a wire is turned over to the right, the bolt slides back to let the wire pass, and immediately shoots forwards and retains it, so that in placing a piece of music on the desk, all that is necessary to be done is to place the lower margin of each leaf separately in the hook of its respective wire, and turn the wires successively over to the right, where they are all held by the catch, the first page of the music being uppermost. It will now be evident that, if each of these wires be successively released, its spring will draw it over to the left, carrying its respective leaf with it, but as the sliding back of the catch would release all the wires at once, in order to release only one at a time, the bolt is made capable of an oscillating movement on a centre pin, and is provided with a knife edge projecting the thickness of one wire from the back of the catch. As the catch oscillates on its centre pin, the knife edge first passes behind the front wire retaining all the rest, and the front part of the catch then releases the first wire, and allows its respective spring to turn over the first leaf, and so on releasing one wire at a time at each oscillation of the spring catch. The oscillation of the catch is effected by means of a string or wire which may either be pulled by the hand or connected to a pedal, and worked by the foot. *Patent abandoned.*

3243. C. F. Claus. *Improvements in carboy hampers, and in the machinery or other means used for manufacturing the same.* Dated December 3, 1862.

This invention consists—1, in substituting hampers made of wire, or even hoop iron, covered or coated with tar, varnish, lead, or alloys of lead, for those now in use made of willow, twigs, cane, &c.; 2, in the means and machinery used for manufacturing the same, which consists in weaving the wire or hoop iron round a metal or wooden mandril representing the shape of the hamper. The invention consists—3, in coating the carboy hampers with lead, or an alloy of tin and lead, or similar alloys. *Patent completed.*

3245. W. H. Browne. *Improvements in gas stoves.* Dated December 3, 1862.

For the purposes of this invention, the inventor arranges over a gas burner of a circular or other form, such as is now commonly employed in gas stoves, a dome, either of fire clay or stone, or other similar mineral material, which is a bad conductor of heat. This dome covers the burner and absorbs the heat produced by the combustion of the gas, which in turn it radiates off and communicates to the air with which it is in contact. There is a hole in the top of the dome to allow the draft from the gas burner to escape upwards. *Patent abandoned.*

3246. J. J. Abadie. *Improvements in the manufacture of imitation lace and gimpure veils and other analogous articles.* Dated December 3, 1862.

This invention has for its object to produce these articles with a better appearance and more resembling real hand-made lace than the imitations at present employed for the purpose. The first improvement consists in manufacturing the spotted or figured groundwork with a plain border of such width that the ornamental or figured border may be attached thereto by sewing or otherwise, without the risk of the pattern being spoiled by a spot or flower of the groundwork interfering with the ornamental border. Another improvement consists in making the ornamental border symmetrical—that is, the flowers, leaves, or other designs of which the border is composed, are made to gradually decrease in size from the central part towards the extremities of the border, and, moreover, the symmetrical curves of the pattern or design are made complementary one to the other on the different sides of the central part—that is to say, if the pattern on one side has curves directed to the right, the pattern on the other side, although of the same character, will have curves directed to the left. This symmetrical arrangement of the pattern of the border is produced by the arrangement of the pattern cards of the jacquard apparatus, which are specially prepared and arranged in the series to effect this object. The last improvement relates to guipure lace, and consists in weaving into the fabric a stout thread or threads to which the ground threads will be secured, so that, when the piece is divided up, the stout threads thus introduced will form a kind of selvage, whereby the guipure may be connected to the ground fabric which it is intended to ornament. *Patent abandoned.*

3247. A. F. Eden. *Improvements in apparatus for taking minute photographic pictures and magnified pictures of microscopic objects.* Dated December 3, 1862.

This invention consist—1, In adapting to the object end of the camera a small removeable box or dark chamber, in which is placed the glass plate with the sensitive surface when it is desired to obtain a minute photographic picture. In order to obtain an enlarged or magnified picture of a microscopic object, the latter is placed in the small removeable dark chamber, and light is admitted throughout a proper aperture, and allowed to pass through the object, and also through an arrangement of lenses which will throw the magnified image on to a sensitive surface placed at the proper focal length behind. From this explanation, it will be understood that this small box or dark chamber performs a double office, depending upon the nature of the operation that is to be performed. To facilitate the operations of the photographer, this box or dark chamber is made to work in guides or dovetailed grooves, so that it may be easily removed from the camera and replaced when required. Another improvement consists in placing behind the lens, and in front of the negative, a stop with a very small aperture, in contradistinction to the large apertures of the ordinary stops. The patentee finds by experience that, for producing good results in making micro-photographs, the aperture of the stop should not exceed the fiftieth of an inch in diameter, and that, in good lights and under favourable circumstances, a much smaller aperture may be advantageously employed. Another improvement consists in adapting to the object end of the camera a focussing lens, which is screwed on to the small removeable box or dark chamber, and is adjusted by means of a sliding tube. *Patent completed.*

3248. C. H. Roeckner. *An improved method of constructing coffer-dams and other similar structures for enclosing or keeping back the flow of water and preventing inundations, and apparatus for raising and lowering weights.* Dated December 4, 1862.

This invention consists in driving piles across the bed of a river or other watercourse at some distance from each other—say 2 ft., 3ft., or 4 ft. apart—and, according to circumstances, instead of driving the said piles close together in two or more rows, and running clay between, as hitherto practised. To obviate the use of clay, the inventor proposes to employ a strong woven material or fabric, such as a sail cloth rendered waterproof by any known means. This fabric he stretches across the entire line of piles, and he proposes that the depth of the said fabric be considerably more than the depth of the river or other watercourse from the top of the said piles, in order that a part of the said fabric shall lie on the bed of the river or other watercourse. *Patent abandoned.*

3249. H. Swan. *Improvements in stereoscopic apparatus.* Dated December 4, 1862.

According to this invention, the patentee combines stereoscopic pictures with pieces of glass or transparent crystal of suitable form, in such manner that the pictures which are in fact depicted on the exterior of the glass or crystal, or on surfaces placed in contact with, or at a small distance from them, shall produce an image apparently solid and imbedded in a glass or crystal. *Patent completed.*

3250. J. Grant. *Improvements in the construction of turn-tables for portable railways.* Dated December 4, 1862.

This invention consists in a novel mode of constructing a very light and portable turn-table, so that it may be easily moved from place to place, and very easily and quickly placed in position upon the surface of the ground, without requiring to be let into it, and so that four-wheeled carriages or trucks may be turned thereon, so as to be brought at any required angle to their former track, and in a line with any one of any number of branch lines or turn-outs that may be radiating from the centre of the turn-table, or so as to be turned completely round in the direct track. *Patent completed.*

3251. R. D. Kay. *Improvements in the manufacture or finishing of endless machine blankets, or endless lappings for printing purposes.* Dated December 4, 1862.

The patentee, in carrying out this invention, takes an endless fabric of wool, cotton, or linen, or of a combination of all or any of those materials, and which has been woven endless of a given length or circumference and width, in a manner well-known amongst manufacturers of endless fabrics; or he takes an endless fabric of the same material or materials as above, separate or combined, which has been woven as a piece with ends, the warp thread ends of which piece have been twisted together so as to form an endless fabric, in a manner also well-known amongst manufacturers of endless fabrics; and he applies equally over the outer and inner surface of such endless fabrics, or over either surface thereof, a coating consisting of india rubber, or of a compound of india rubber and other substances, and when so coated (if necessary), he applies as a covering to either or both surfaces a woven fabric consisting of cotton, linen, or wool, either separate or combined, likewise coated with india rubber, or with such compound as aforesaid. The coating of such an endless fabric may be effected with a brush, doctor, knife, or roller. He applies the coated covering-fabric first to the outer, and then, if necessary, to the inner surface of the endless fabric, by pressure with rollers, or other suitable tools or instruments. *Patent completed.*

3252. J. Braddock. *Certain improvements in machinery or apparatus for effecting the separation of impurities from the water employed in steam boilers, and also for effecting the circulation of the said water.* Dated December 4, 1862.

This invention relates to the cleansing of water employed in steam boilers, and in separating the floaing particles, impurities, or extraneous matters therefrom by allowing the impure matter to subside or fall to the bottom of a chamber within the boiler, where it can deposit in the form of a sediment, without being disturbed by the motion caused by ebullition. The improvement consists in the application of the steam in the boiler to raise the water from the bottom of the boiler to the said chamber situated partly or entirely above the water line. *Patent completed.*

3253. F. D. Dely and T. C. Gibson. *Improved means and apparatus, whereby petroleum and other oils and hydrocarbons can be safely carried and stored.* Dated December 4, 1862.

The main feature of this invention is the use of a water or other inodorous liquid seal for the end of a pipe or pipes communicating with a tank or tanks, vessel or vessels, containing the oil. *Patent abandoned.*

3254. G. Lewal. *A hot air apparatus in cast iron or in any other metal or substance consisting of prismatic tubes, to be applied to chimneys with flues and heat conduits.* (A communication.) Dated December 4, 1862.

This apparatus consists of a box, in the bottom or lower side of which there is a hole to communicate with the external air, and in the top or upper side a grating pierced with three or more ranges of square holes diagonally, and to each of these holes is adapted a vertical tube, all communicating with a cylinder placed parallel with the box. The cylinder communicates with the apartment either by having the ends open, or by extra pipes, so as to make the openings into the apartment wherever it is desired, but which openings should be on a higher level than the cylinder. The apparatus thus constructed is placed in the inside of the chimney over an air-hole made to communicate with the external air by means of a pipe, flue, or any other means, so that the hole in the bottom of the box corresponds with the said air-hole. The apparatus is placed in the chimney slantingly, so that the bottom should be about 1 ft., and the top about 3 in. from the front of the stove or grate, and would replace the backs now in use of such stoves or grates. The principle of the invention is to divide the heat produced by combustion, and make it work round the tubes, and thus increase the heating surface, so as to utilize the whole heat produced by the fire, therefore there should be several tubes, although the number is a matter to be determined by the size of the chimney. *Patent completed.*

3255. H. CASTELBON. *An improved press to be used in the manufacture of tiles and bricks.* (A communication.) Dated December 4, 1862.

The press, the subject of this invention, is composed of the following parts:—A main framing carrying the press, a second framing serving as guide to the coffin, or upper mould corner, and three shafts. The first shaft carries a fly-wheel and transmits motion on to the second shaft, which gives a come-and-go motion to the coffin, and, consequently, to the upper mould by means of a connecting rod. The third shaft carries a wheel on which the lower moulds are placed. There is a mould or rectangular box intended to receive and mould the clay; also a second connecting rod giving intermittent quarterly turns to the wheel which carries the lower moulds, and a balance-catch working the ratchets of another connecting rod, on which is a rack regulating the stopping. A cake of clay being deposited, the second shaft is made to turn and draw the coffin or upper mould carrier, which presses the cake of clay, and gives it the required form, while the slide bars prepared a fresh supply of clay, which is cut and brought forward by a moveable apron arranged to fall under the second mould when it has arrived at the proper point. The tiles or bricks are thus prepared, and while the upper mould rises again, the connecting rod completing its journey turns a pinion carrying the balance catch, which comes against one of the branches of the ratchet of a cross-bar wheel, thus giving motion to the shaft carrying the wheel which is to bring another bed beneath the upper mould, and which then turns. This machine itself prepares the clay by means of crushing cylinders or a malaxing barrel. *Patent abandoned.*

3256. J. ROBINSON. *Improvements in the construction of ships and vessels.* Dated December 4, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3257. J. BIGGS, J. JOHNSON, T. RICHARDSON, and T. ARNOLD. *Improvements in the manufacture of warp fabrics.* Dated December 4, 1862.

This invention consists in a mode of manufacturing elastic or looped corded or ribbed fabrics in warp machines. For this purpose the patentees combine two well-known systems of looping of the warped threads on the needles of warp machines. Thus, in making the parallel corded, ribbed, or more prominent parts of a fabric, they employ what is known as the "double lap," and according as they require to make wider or narrower cords or ribs, they produce in succession a greater or less number of courses of double lap, and then, according as they wish to have a wider or narrower space between the succeeding cords or ribs, they produce in succession a larger or smaller number of courses of "single lap;" thus there are to be alternately produced several courses of double lap, to obtain the desired width of cord or rib across the machine, and then two or more courses of single lap between the cords, and thus in regular succession till the desired length of fabric has been made. *Patent completed.*

3258. R. WALLIS. *Improvements in apparatus for loading and unloading vessels, and transporting sacks, casks, and other packages or parcels from one landing place or stage to another, or to or from one warehouse to another.* Dated December 4, 1862.

This invention consists of improvements in apparatus or mechanism whereby goods, merchandize, minerals, and various articles in sacks, casks, or packages may be moved from one place to another by causing the same to be drawn by hauling ropes, or other equivalents, across suitable strong ropes, bands, or chains stretched or extended between two places. *Patent completed.*

3259. A. HORNSBY. *Improvements in apparatus for cutting and pulping turnips and other vegetables.* Dated December 4, 1862.

For the purpose of cutting turnips and other vegetables, the patentee employs a disc or wheel mounted on a horizontal axis, and capable of being caused to rotate by means of a crank handle or otherwise. The roots or vegetables to be cut are placed in a hopper, and rest against the revolving disc or wheel, and this has knives upon it suitable for cutting the roots of vegetables into small pieces; the pieces as they are cut pass through passages left for them in the disc or wheel, and fall down on the other side into another hopper placed to receive them. Up to this point, however, the machine is not new, but such machines, as usually constructed, are defective in that they allow the last slice of the root or vegetable to escape as a single piece much exceeding in size the other pieces; this arises in consequence of its being necessary to leave a space at the bottom of the feeding hopper for the knives on the disc or wheel to pass, and hence, as soon as the root or vegetable is reduced to a slice sufficiently thin to pass this opening, it falls through as a completed slice. Now, according to this invention, the patentee, in the following manner, receives the slices so falling through, and returns them to the feeding hopper, and in this manner he ensures their being properly cut up. Below the bottom of the feeding hopper he places a vertical board or screen parallel to the vessel or disc, and at such a distance from the lower part thereof that the knives will just pass clear; and he also forms a flange projecting inwards on or near the periphery of the disc or wheel. It results from this arrangement that the slices that fall through are retained between the vertical board or screen and the flange on the disc or wheel, and the knives, as they sweep round, bring them up again into the hopper. *Patent completed.*

3260. T. G. WEBB. *Improvements in the manufacture of articles of pressed glass.* Dated December 4, 1862.

This invention relates to articles of capacity formed of flint glass, such as decanters, cruets, pickle jars, and toilets, and consists in a method of producing the bottoms thereof. The method by which the patentee accomplishes it is to form the bottom in a mould separate from that which is used for the upper part. The two portions being thus formed as distinct pieces, may be provided with any design capable of being pressed, after which they are heated (if such heating be required) to the necessary temperature, and united as is practised in joining pieces of glass for ordinary purposes. In order to effect a correct junction, he uses guides, against which to slide the one part, so that it may be adapted to the other centrically. This object may also be attained by leaving the bottom piece in the mould by which it has been formed, and then effecting the junction, the said bottom in such case constituting the guide. *Patent completed.*

3261. M. TILDESLEY and E. SHARPE. *Improvements in the manufacture of earthenware knobs, and in fixing them in spindles used with certain kinds of knobs, in securing the metal mounts upon such knobs, and in apparatus to be employed in certain parts of this manufacture.* Dated December 5, 1862.

This invention refers—1, to the manufacture of earthenware knobs, by moulding them in metal moulds lined with plaster of Paris. The sinking on the back of the knob for the mount and spindle, or for the screw, as the case may be, is formed by employing a plug of fired earthenware surrounded with plaster of Paris, the plaster being protected at the bottom by the form of the plug, which resembles a piston with its rod covered with plaster, which the inventors find less likely to adhere to the moist clay. This sinking they make square in section, by preference. They pierce the holes for the running of metal, which is intended to secure the mount or screw longitudinally in the knob, by employing a peculiar instrument formed similarly to a pair of glove stretchers, with a horizontal pin or stud upon the end of each limb; the tool, when closed, will pass into the sinking for the mount; pressure by the hand then forces the pins or studs laterally into the clay, whence they can be again withdrawn by releasing the pressure. The improvement in securing together the knobs and mounts or screws, consists in employing an alloy of metal run into the holes described. The improvements in the spindles consist in grooving them on all four sides throughout their entire length, by rolling the iron in suitable rolls to any necessary length, and then cutting up the rod thus produced into lengths for each spindle. *Patent abandoned.*

3262. L. CHRISTOPH, W. HAWKSWORTH, and G. P. HARDING. *Improvements in drilling, drawing, and rolling metals, and in the machinery or apparatus to be employed therein.* Dated December 5, 1862.

This invention relates—1, to the drilling of metals, and consists in the application and use of a number of stationary drills made to operate upon several pieces of metal simultaneously, such pieces of metal having a rotating motion imparted to them whilst under the action of the drills, in lieu of the rotary motion being given to the drills themselves, as heretofore. The drills are so shaped in any well-known manner as to clear themselves readily from the fragments of metal or drillings during the drilling operation, and the ordinary well-known means are employed for feeding the drills or the metal onwards as fast as the operation proceeds, the speed varying according to the size of bore under operation. Another portion of this invention relates to the drawing of metals either in a hot or cold state, and consists in the employment for that purpose of a screw spindle, in lieu of the traversing chains hitherto employed in draw benches. *Patent completed.*

3263. E. B. WILSON. *Improvements in railway wheels, and in the mode of manufacturing the same.* Dated December 5, 1862.

This invention relates to a peculiar construction and arrangement of railway wheels, whereby greater economy and simplicity of construction are combined with increased safety in case of fracture of the tire. According to this invention, two discs of the desired size are first prepared by casting in malleable metal, and are then placed in dies and subjected to compression or hammering therein for the purpose of giving them the desired form, whether flat, disced, or corrugated. These dies are also so shaped as to produce a raised annular rim all round, or partly round the circumference of the discs on one side thereof, such rim being either parallel, V-shaped, or of any other sectional form. The tire has corresponding annular grooves formed inside it so as to fit accurately over or into the rims of the two discs, which are placed inside the tire from opposite sides thereof, and may, or may not, be held therein by bolts passing through the discs. The space between the discs may be filled in with india rubber, cork, wood, or other good sound-deadening material. *Patent completed.*

3264. J. E. BLACKWELL. *Improvements in barometers or instruments for measuring altitudes, or the pressure of the atmosphere or elastic fluids.* Dated December 5, 1862.

This invention relates to a novel mode of constructing these instruments, so as as to make them portable, and yet at the same time exceedingly sensitive and accurate. The desired object is effected in some of the improved instruments by a combination of several separate improvements; but, in other instruments, some only of the improvements are comprised. In all the improved instruments, however, the variations in pressure are ascertained by means of elastic vacuum chambers, as in the ordinary aneroid barometer; and the patentee finds it convenient to employ four or more elastic chambers arranged in groups or sets, so that the inequalities of pressure or inaccuracies of action in any of the several chambers shall be compensated by the others. In all the instruments these vacuum chambers are directly attached to or connected with helical or other springs, the power or elastic force of which has been previously ascertained with great care, and which reciprocate the expansion or compression of the chambers accordingly as they are acted upon by diminished or increased pressure. *Patent completed.*

3265. J. M. RIGBY. *Improvements in presses for pressing cotton or other fibrous materials.* Dated December 5, 1862.

This invention consists of an improved construction of a portable hand press, adapted for pressing small bales of cotton or material preparatory to the final pressing by hydraulic apparatus. The outer box or framework with the press head and pressing plate are made of suitable materials in any desired manner. At the top of the framework at each end, the inventor employs a shaft, having fixed to it a ratchet-wheel and two sets or series of teeth, which enter the links of strong chains, or gear into racks connected at one end to bars in contact with the under surface of the pressing plate. Each of the aforesaid shafts is made the fulcrum of a long lever, carrying a ratchet for acting on the ratchet wheel, so that when the levers are moved up and down, the ratchet wheels are turned, and with them the shafts and teeth, by which means the chains or racks and pressing plate are gradually pulled up and press the material. *Patent abandoned.*

3266. P. COWAN. *An improved method of purifying gas.* Dated December 5, 1862.

The object of this invention is the purifying of gas, and the invention consists in the employment, for that purpose, of animal charcoal, or of vegetable charcoal, or of other form of carbon. The inventor places the charcoal or carbon in purifying vessels of the ordinary or other form, into which he conveys the gas. From these vessels the gas is conducted, the charcoal or carbon having removed the impurities from it. *Patent abandoned.*

3267. W. J. SMITH. *Improvements in the manufacture of collars, cuffs, and wristbands.* Dated December 5, 1862.

This invention consists in making collars and cuffs, or wristbands, of india rubber, and by preference of vulcanized india rubber. Such collars, cuffs, or wristbands are intended to take the place of the ordinary collars, cuffs, or wristbands now made of cotton or linen, or such like fabrics. *Patent completed.*

3268. E. WALTON. *An improved article of wearing apparel for the neck.* Dated December 5, 1862.

This article of wearing apparel consists of portions of a collar and of a tie or scarf combined in one. The inventor takes a length of washable or other material suitable for scarfs, and hollows it for a certain portion towards the central part, and on one side of the material into a curve to suit the neck. He then sews on to those parts which when worn come in front and at the sides of the neck of the wearer pieces of linen stitched to resemble portions of an ordinary collar, while he applies a stitched band of linen extending round the back of the neck on the upper part of the material forming the scarf or tie. This combined article, when on the wearer, has the appearance of an ordinary collar and scarf. *Patent abandoned.*

3269. C. GALLETI and F. STEFANO. *Improvements in articles of furniture.* Dated December 5, 1862.

This invention relates to a combination of parts whereby the inventors are enabled to make either a table (dining table by preference) or a whatnot at pleasure. The several stages or trays of the whatnot correspond with the leaves or flaps that form the table, and which may be two, three, or more in number, according to the size of the table required. The one end of the dining table is supported on two feet somewhat like the feet of an occasional table, which feet form the sole support when converted into a whatnot. In this end of the table they place a drawer, which, when used as a whatnot, forms the lower shelf with drawer therein. The flaps or shelves are connected together by rods jointed thereto, and so arranged that it is simply necessary to raise the proper end of the table till the connecting rods (which, when as a table are in pairs, close together and form the two side rails of the table) are in an upright position, and form the four uprights or corner pillars of the whatnot, the several leaves of the table keeping the whole time in their horizontal position, and assuming the proper position for the shelves of the whatnot. The reverse movement converts the whatnot into a table; suitable legs are fixed to one of the shelves to support the other end, which, when raised as a whatnot, come up behind it. When as a whatnot, the inventors secure it in that form by a locking action applied to the parts jointed together. *Patent abandoned.*

3270. H. A. BONNEVILLE. *Improvements in the fabrication of stockings and socks.* (A communication.) Dated December 6, 1862.

This invention consists in making stockings and socks tapered and proportioned without seams, and stockings and socks cut to the necessary shape, and joined equally without seams, by means—1, of a new method of applying the rectilinear stocking frame, the ordinary circular frames, and Delarothière's tapering machine; 2, by means of some newly-invented stitching processes, named "Bezard's stitching process," which are substituted for the seams in uniting any kinds of meshed fabrics, woven or otherwise, either with or without selvages; 3, by means of a foot, which, although made on a circular frame, is narrower than the leg, with diminutions at the instep, or with a pattern having that appearance; 4, by means of a tapered and selvaged heel without seams; 5, by means of a new application of hand-stitching for finishing the extremities of the toes and heels; 6, by means of a sort of pattern imitating contractions, which may be changed at will, and which are made with the selvages at the toes, the calf, and the instep, as well as the imitation of the instep on the circular frame. *Patent completed.*

3271. R. THORP. *Improved coating or covering for steam boilers and other surfaces to prevent the radiation of heat.* Dated December 6, 1862.

This invention for the covering of steam boilers and other like surfaces, to prevent the radiation of heat, consists in enclosing the external portion of the boiler or other surface with a covering of sheet iron, or other suitable metal, so as to form a cavity between the outer surface of the boiler or other surface and the inner surface of the sheet metal, filling the cavity with dry sand (by preference sea sand), and in covering the outer surface of the metallic casing with a skin or coating of plaster of Paris, or other like suitable non-conducting material, and which it is preferred to case in, or cover with, wood lagging. *Patent abandoned.*

3272. J. and M. CRAIG. *Improvements in apparatus for the manufacture of clay.* Dated December 6, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3273. G. WRIGHT. *Certain improvements in the preparation and manufacture of food for cattle.* Dated December 6, 1862.

The patentee claims the preparation and manufacture of a cake for feeding cattle compounded of a nutritive oil seed meal base, with one or more condimental elements of a tonic, carminative, stimulative, corrective, antiseptic, or other sanitary character, and likewise the manufacture of oil seed cakes denoting their weight by the means of indentations or perforations upon one or both of their surfaces, as set forth and described. *Patent completed.*

3274. W. McNaught. *Improvements in machinery for washing and drying textile fabrics and materials.* Dated December 6, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3275. J. Campbell. *Improvements in means or apparatus for heckling or hackling flax and other fabrics.* Dated December 6, 1862.

The objects of these improvements is to ensure uniformity in the traverse of the holders carrying the sticks of fibre, and, consequently, in the operation of the teeth or hackles upon the fibre carried by various holders. For this purpose, the patentee applies one or more stops or catches to the traversing means in position to receive the holders and control their position thereon, so as to prevent any of the holders being pushed out of time along such traversing means, and a consequent partial working of the fibre of such holders. *Patent abandoned.*

3276. G. Burchall and E. Borrows. *Improvements in propellers for ships and other navigable vessels.* Dated December 6, 1862.

The object of this invention is to prevent the vibration in ships and vessels fitted with paddle-wheels of the description now in use, to produce or construct propellers less liable to damage from ice and other hard substances in the water, and to obtain, by the use of such propellers increased speed from the employment of an equal amount of motive power. On both sides of ships and other vessels, and in similar positions to the ordinary paddle-wheels, the patentees place one, two, or more propellers, partially immersed in the water, resembling in form the stern submerged screw-propellers generally in use. The blades are sometimes for small and coasting ships cast with the boss, which is secured to the driving shaft, but usually and by preference so formed and secured to the said boss, that the angle at which the said blades enter and leave the water, and the depth of immersion, can be accommodated to the water line. These propeller blades may be secured by bolts or pins to the boss, and strengthened by stays; but, in all cases] they dispense with rings round the outer circumference. *Patent completed.*

3277. E. and W. Ullmer. *Improvements in cylinder printing machines.* Dated December 6, 1862.

This invention consists—1, In obtaining the to-and-fro motions of the printing or type table in cylinder printing machines directly from the driving wheel which is set vertically by means of a connecting rod, one end of which is connected to a pin or stud projecting from the rim of the said wheel, while the other end is attached to the bottom of the printing table. The table has affixed to it a rack which works in combination with a loose wheel on the cylinder shaft for driving the printing cylinder. 2, In holding the printing cylinder in a fixed position during the return of the printing table by a crank or lever attached to the framework of the machine, which lever carries a roller made to travel round a disc keyed on the cylinder shaft, and to engage into a nick or aperture made in the disc. 3, In obtaining the supply of ink for the inking table by means of rollers fitting in slots or grooves in the frame of the machine, which rollers are raised into contact with inking rollers placed above, by inclined blocks or surfaces on the printing table. And, lastly, In obtaining an equal balance on its axis for the cylinder in cylinder printing machines by means of a balance weight fitted to compensate for that portion of the cylinder usually removed. *Patent abandoned.*

3278. R. McClintock. *Improvements in carriage axles.* Dated December 6, 1862.

The objects of this invention are to facilitate the fixing and removal of the wheels, and to diminish friction. Near the outer end of the journal of the axle, the inventor removes a portion from the circumference thereof, and places a split flanged ring or stop in the portion so diminished in circumference; the halves of this ring are kept together by an elastic band which lies in a circular recess cut on the ring. Over this ring, and on the end of the journal of the axle, made square, he places a cap with a broad flange. This cap is secured by a bolt with a threaded end passing through a portion of it and through the flange of, or secured by, one of the halves of the ring; a nut guarded by a moveable button is screwed over the outer end of the bolt of the wheel. The cap and stop lie in a recess hollowed out in the boss or nave. To facilitate and ensure the fixing of the parts, he sometimes causes a tongue to project from the stop and enter a hole bored for its reception in the now removed portion of the journal. To lubricate the axle he applies an oil cup to the collar of the axle, from which the oil flows through a channel made for the purpose and finds its way between the journal and axle box. He prefers to form grooves or channels round the journal. *Patent abandoned.*

3279. R. E. Donovan. *Improvements in the means and apparatus for the prevention of railway accidents.* Dated December 6, 1862.

This invention consists in so arranging one or more plates or bodies, or series of plates or bodies, of metal, wood, or other suitable material, in conjunction with one or more moveable bars, both connected to the carriages, trucks, or locomotive engines of railway trains, that, on a collision taking place, the said bar or bars on coming in contact with another carriage, locomotive, or other obstacle is or are caused to act upon and break, bend, or perforate the said plate or body, or series of plates or bodies, and thus, more or less, gradually expend the force of concussion before the carriage, truck, or locomotive engine can come itself in contact with the obstacle, by which arrangement the engine, carriages, and consequently the passengers contained in the latter, are more or less entirely preserved from injury. *Patent completed.*

3280. J. Jock. *An improved composition or compositions for producing artificial sea-water, or the odour or effects of sea-water.* Dated December 6, 1862.

In carrying out this invention, the inventor uses of bay salt, say one pound; iodine, one drachm; iodide of potassium, one drachm; bromine, six minims; alcohol, one teaspoonful. The process he prefers to adopt is as follows:—The iodine and iodide of potassium are dissolved in, say, half-a-pint of water, and the bromine is added to the solution, which must be kept in a well-stopped bottle or vessel to prevent evaporation or escape of the volatile contents; it must also be kept in a well-stopped bottle to prevent decomposition by light. With this mixture the bay salt is saturated. The bay salt (one pound) is put into a bottle capable of containing double that quantity, and a teaspoonful of the iodine and bromine mixture added thereto. The reason for employing a large bottle or vessel is to allow the perfect admixture of the whole by long-continued agitation. The alcohol is then added, which produces coloured crystals. For bathing, he dissolves a teaspoonful of the crystal with a handful of salt in a quart of water, and adds this solution to a sufficient quantity of water, according to pleasure, for a hip, sponge, or shower-bath, or for a double bath. A bath for total immersion will require two pounds of salt, and a tablespoonful of the crystals. For deodorizing, disinfecting, or tonic purposes, a teaspoonful of the crystals put into a saucer will rapidly pervade a moderate-sized nursery or bed-room with the odour of the sea-coast; the process may be repeated daily, but at the same time proper ventilation should be maintained. *Patent abandoned.*

3281. W. Palliser. *Improvements in screw-bolts.* Dated December 6, 1862.

In currying out this invention, the patentee proposes, in the first place, to reduce the shank of the bolt cylindrically, either in part or throughout the entire length, to the size to which the end is reduced by the screw thread. Instead of this, if it be desirable to do so, he can reduce the bolt in part either about the middle or towards either end; and, supposing it be required that the bolt should thoroughly fill the bolt hole, he can cast zinc or other metal or alloy round the reduced part, and thereby make the bolt of uniform size throughout. In order to diminish as much as possible the amount by which it is necessary that the shank of the bolt should be reduced, he proposes making the screw much shallowed and finer than those in general use. He also prefers that this thread should be of a rounded form, to obviate any tendency there might be in a sharp thread to cause the nut to tear off the end of the bolt. Instead of reducing the shank of the bolt, he can satisfy the conditions above enumerated by forming the screwed part of the bolt of shear steel, or other weldable steel, which he can weld on to the iron bolt in the form of the splice of a fishing rod. He may increase the strength of the steel by tempering it. In the second place, he forms the head of the bolt by rolling or otherwise drawing down the bolt from a bar of iron sufficiently thick to leave the head on the bolt, by means of which the grain of the iron will run in a longitudinal direction. *Patent completed.*

3282. G. Lowry. *Improvements in machinery for hackling flax and preparing to be spun flax, hemp, tow, and such like materials.* Dated December 8, 1862.

This invention consists—1, In a novel combination, arrangement, and adaptation of swivel strippers or stripper rods for the purpose of stripping the tow from the hackles of sheet hackling machines, when and after the hackles have passed through the strike of fibrous material. 2, In an improved method of raising and lowering the gills, needle bars, or fallers of screw gill machines, by the application of an eccentric in conjunction with the bottom screw, and a combination and adaption of levers, the operation of which screw puts into motion a rocking lever to raise or lower the gills or faller bars as may be required. 3, In applying to the improved tow-shaking machine described in the specification of letters patent granted to the present patentee on the 14th day of July, 1862, No. 2016, an apparatus for making laps for tow-carding engines. And, 4, In arranging a perforated ribbed or barrel concentric flexible creeper sheet underneath the working and stripper rollers of tow-carding engines, which creeper carries forward the fibre and allows the dirt, shives, and other impurities to fall to the floor. *Patent completed.*

3283. J. L. Budden. *Improvements in means or apparatus for obtaining and applying motive power for propelling or other purposes.* (A communication.) Dated December 8, 1862.

This invention relates to improvements upon an invention for which letters patent were granted to the present inventor, dated September 22, 1860, No. 2317, for improvements in the application of steam or highly rarified gas or other aeriform fluid to obtain motive power for propelling or other purposes, which invention was communicated to him by Woodford Pilkington. The present improvements consist in the application of a fixed steam guard or guards (by preference of a cylindrical form) to the screw propeller or turbine wheel described in the specification of the patent above referred to, and in the circumference of which the blades or vanes of the screw or turbine wheel revolve. The guard is suitably fixed so as to be entirely independent of the "screw" or "turbine" wheel revolving within it. The inner circumference of this steam guard is furnished with floats or steps which cross the direction of the pitch of the screw, somewhat like the steps of a treadmill, or teeth of a wheel with internal cogs, and upon which the steam or other propelling medium is caused to impinge as it issues from the passages terminating at the periphery of the blade or vanes of the screw or turbine wheel, by which arrangement, in the application of this invention to a submerged screw propeller, the steam or other fluid in discharging is projected against the "steam-guard," in place of going directly into the water, as described in the former specification. *Patent abandoned.*

3284. *Improvements in the manufacture of pulp or half-stuff used in the manufacture of paper, pasteboard, and similar articles.* Dated December 8, 1862.

This invention consists of using the fibrous portion of potatoes either with or without any portion of the skins and farinaceous part thereof, in the manufacture of paper pulp or half-stuff. If used in conjunction with linen or other half-stuff the proportions must be regulated at the discretion of the manufacturer, according to the quality of paper, pasteboard, or similar articles required to be made, because if the whole of the skins are worked up in the pulp, the product will be suitable only for the manufacture of inferior paper or other articles. *Patent completed.*

3285. P. Todd. *Certain improvements in "pickers" used in looms for weaving.* Dated December 8, 1862.

This invention consists in the combination of wood and leather to form such pickers. The leather is the portion arranged to strike the shuttle, and the wood is used as a foundation upon which to fix the leather by means of wire or cement, by which combination the leather tips may be renewed when required, the wood being more durable than leather; thus the whole picker is not destroyed when the striking portion is worn away, as in most instances. This arrangement also enables scrap leather to be employed in the formation of the picker ends. *Patent completed.*

3286. R. A. Brooman. *Improvements in kneading machines.* (A communication.) Dated December 8, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3287. G. A. Huddart. *Improvements in buttons.* Dated December 8, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3288. C. Sanderson. *An improved mode of manufacturing driving bands for driving machinery, lifting weights, and other analogous purposes.* Dated December 8, 1862.

This invention consists in making these articles of thin sheet steel or other metal, cut to the width of the intended driving or lifting band, and coated or protected in a peculiar manner by india rubber, so as to preserve the metal from oxydation. *Patent completed.*

3289. W. E. Newton. *Improvements in preserving animal substances.* Dated December 8, 1862.

This invention relates to novel methods of preserving animal substances by means of chemical agents. These methods differ as to whether the ingredients to be preserved are intended to be employed for alimentary or industrial purposes. For alimentary substances, nitrates of various bases may be employed, in the manner hereafter described, but the neutral nitrate of alumina is preferred. Preference is given to this salt, inasmuch as it does not change the flavour of the meats, does not coagulate the albuminons parts, nor does it in any manner change their alible properties; it is also perfectly innocuous in a hygienic point of view. *Patent abandoned.*

3290. J. Hilliar. *Improvements in hinges, joints, or connections, and in applying them, parts of which improvements may be employed for constructive and decorative purposes.* Dated December 8, 1862.

This invention consists in the manufacture or construction of a joint hinge or connection by using oval or other suitably shaped tubes, such tubes having an opening or slit from end to end. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated February 27, 1863.

557. A. Dudgeon and G. F. L. Meakin, 4, Martin's-lane, Cannon-street, surveyors, and E. E. Allen, 5, Parliament-street, Westminster, engineer. Improvements in the construction of underground railways or subways, and in carriages to be used or worked therein.

Dated May 23, 1863.

1300. F. Potts, tube manufacturer, and J. Key, Birmingham. Improvements in the manufacture of certain descriptions of iron tubing, and in the means of producing and applying an ornamental case to the same, which said means are also applicable to the production of ornaments in metal for other purposes.

Dated May 28, 1863.

1337. C. T. Boutel, Quai Mariemont, Brussels, engineer. A new or improved instrument for measuring distances and altitudes.

1339. C. E. Laederich, Paris, gentleman. Improvements in watches.

1343. F. Osbourn, Peckham, tailor. Improved apparatus for pressing, smoothing, and finishing garments or parts of garments.

1345. T. Jarvis, Earl's-court, chemist. Improvements in obtaining vegetable extracts, and in apparatus employed therein.

1347. W. Needham and J. Kite, patent filter press works, Vauxhall, manufacturers. Improvements in expressing liquid and moisture from substances, and in separating the liquid from the solid portions thereof, applicable also to the filtration of liquids.

Dated May 29, 1863.

1348. E. Ironmonger, Friar-gate, Derby, auctioneer, upholsterer and furniture dealer. An improved loose clip and socket joint, applicable to bedsteads, sofas, chairs, and other articles of furniture and of fencing.

1349. A. Abadie, Fecamp, France, manufacturer. Improvements in railway breaks.

1351. J. J. Pôtel, Saint Quentin, France, engineer. An improved method of accelerating the draft in furnaces and fire-places.

1353. R. Barker, Grafton-road, Upper Holloway, gentleman. Improvements in the manufacture of matches usually termed "Vesuvians."

1355. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in the manufacture or preparation of lubricating material. (A communication.)

Dated May 30, 1863.

1359. J. Heard, Crediton, Devon, engineer. Improvements in apparatus for distributing manure.

1361. S. Bates and J. Jardine, Radford, Nottingham, bobbin and carriage manufacturers. Improvements in carriages used in machines employed in the manufacture of lace or other fabrics.

Dated June 1, 1863.

1363. J. Henson, Parliament-street, Westminster, civil engineer. Improvements in the construction of railway carriages.

1365. W. Clark, 53, Chancery-lane, engineer. Improvements in apparatus for printing fabrics, papers, and other surfaces in colours. (A communication.)

1367. L. S. Chichester, Brooklyn, New York. Improvements in means for drying grain.

1369. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. An improved construction of marline spike. (A communication.)

1371. H. C. Coulthard, Park Iron Works, Blackburn, Lancaster, engineer. Improvements in packing for the glands of piston rods and other moving mechanism, where it is necessary to prevent the passage of steam or other fluids.

Dated June 2, 1863.

1373. A. Illingworth, Halifax, boot and shoemaker. Improvements in boots and shoes or similar coverings for the feet, and in the manufacture thereof.

1377. G. A. Barrett, W. Exall, C. J. Andrewes, and A. Barrett, Reading, engineers. Improvements in valves and apparatus for regulating the speed of steam engines. (Partly a communication.)

1379. E. J. Jarry, 29, Boulevart St. Martin, Paris, merchant. Improvements in machinery to be worked by steam or other power for clearing and ploughing land.

1381. R. Crawford, Beith, merchant. Improvements in jacquard machines used for weaving ornamental fabrics.

1383. W. Gleave and T. Young, Manchester, engineers. Certain improvements in apparatus for feeding or supplying water to steam boilers.

Dated June 3, 1863.

1387. G. Davies, 1, Serle-street, Lincoln's-inn, civil engineer. Improvements in machines for "ginning" cotton. (A communication.)

1389. F. S. Barff. An improved means of protecting, preserving, and hardening surfaces of brick, cement, stone, stucco, and other analogous substances, which invention is also applicable to the preservation of timber.

1391. J. Portlock, Hampstead-road, gun maker. An improved alarum apparatus.

Dated June 4, 1863.

1393. S. Blake and T. Lee, Chester, millers, and R. Dutton, Chester, millwright. Improvements in the construction of flour and meal mills.

1397. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in the construction of casks, barrels, kegs, and other analogous articles. (A communication.)

Dated June 5, 1863.

1398. S. St. B. Guillaume, 81, Marland-place, Southampton. Improvements in bricks, and in apparatus to be used in manufacturing the same, and in brickwork built therewith.

1399. F. A. Calvert, Manchester, engineer. Certain improvements in steam engines, steam boilers, and steam heating apparatus.

1403. T. Gray, Lower Mitcham, bleacher. Improvements in treating flax, hemp, and other vegetable fibrous substances in order to bleach and separate the fibres.

1405. W. Clark, 53, Chancery-lane, engineer. Improvements in the distillation and separation of hydrocarburets and their derivatives, and in apparatus for the same. (A communication.)

Dated June 8, 1863.

1407. W. A. Brown, 3, Victoria-terrace, Hawks-lane, Canterbury, civil engineer. An indicator for railway trains.

1409. A. J. Hollingsworth, 9, Oxford-street, Southampton. A new or improved spirit-compass with screw lever.

1410. C. E. Newcomen, 20, Ovington-square, Brompton. Improvements in the treatment of peat and other substances containing moisture.

1413. W. C. Brocklehurst, Macclesfield, silk manufacturer, J. Creighton, C. Makinson, and J. Creighton, Manchester, machinists. Certain improvements in machinery or apparatus for winding yarns or threads.

1415. W. Clark, 53, Chancery-lane, engineer. Improvements in mounting and fitting bedsteads, chairs, and other moveable seats on board ship. (A communication.)

1417. E. A. Schofield, Eyam, Derby, boot manufacturer. Improvements in tools or apparatus for paring, rasping, and scraping the edges of boot and shoe soles and heels.

1419. W. E. Gedge, 11, Wellington-street, Strand. Improvements in the construction of kites. (A communication.)

1421. E. Humphrys, Deptford-pier, engineer. Improvements in surface condensers.

1423. H. Reynell, gentleman. Improvements in the manufacture (by the introduction of cocoa-nut husk or part thereof) of a substitute for ordinary felt and kamptulicon, and in utilizing said cocoa-nut husk or part thereof for packing of wine coolers, refrigerators, and ice chests, and caulking of ships and vessels.

1425. W. E. Newton, 66, Chancery-lane. Improvements in nozzles for hose and water-discharge pipes. (A communication.)

1427. T. Page, Adelphi-terrace, Strand, civil engineer. Improvements in propelling vessels, and in apparatus for the same.

Dated June 9, 1863.

1429. B. Dobson, Bolton, machine maker, and D. Greenhalgh, manager. Certain improvements in machinery or apparatus for preparing cotton and other fibrous substances.

1431. C. Niquet, Paris, gentleman. Improvements in apparatus for sorting and washing ores.

1433. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in the distillation of bituminous substances. (A communication.)

1435. H. Martin, Surrey-square, Old Kent-road, land agent. Improvements in treating and preparing night soil and sewage with other materials as a manure.

1437. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in the propulsion of ships and other vessels. (A communication.)

1439. H. Bessemer, Queen-street-place, New Cannon-street. Improvements in the construction of and mode of working hydrostatic presses and hydraulic apparatus.

Dated June 10, 1863.

1441. R. Aitken, Cambridge-street, Pimlico, civil engineer. Improvements in the permanent way of railways.

1442. T. Adams, 5, Alfred-terrace, Spa-road, Bermondsey. Improvements in slide and other valves, and apparatus connected therewith.

1444. T. Brooke, Bar-street, Laister Dyke. Improvements in miners' lamps.

1445. W. Wells, Manchester, engineer, and J. W. Myers, pattern maker. Improvements in apparatus for obtaining artificial light from volatile liquids or fluids.

1447. W. Clark, 53, Chancery-lane, engineer. Improvements in locomotive apparatus, which is also applicable to other purposes. (A communication.)

Dated June 11, 1863.

1451. M. Henry, 84, Fleet-street, patent agent. Improvements in treating floss silk and silk waste, and in apparatus for the same and other like purposes. (A communication.)

1453. E. Deane, 1, Arthur-street East, London-bridge, engineer. Improvements in cooking and culinary utensils.

1457. W. Walton, Smethwick, coppersmith. An improved pneumatic hammer, useful also for punching and stamping metals.

1458. J. A. Schlumberger, Basle, Switzerland, manufacturing chemist. Improvements in the preparation of aniline dyes or colouring matters for dyeing, staining, or printing textile substances.

1459. W. Seed, Derby-street, Preston, machine maker. Improvements in machinery for drawing, slubbing, roving, and spinning cotton and other fibrous material.

1461. J. Johnson, Peterborough, engineer. Improvements in lubricating apparatus for the cylinders of steam engines.

1463. T. A. Elliott, Enniskillen, Fermanagh, civil engineer. Improvements in reefing topsails and courses.

Dated June 12, 1863.

1464. W. Sims, Reading, brewer. A new compound extract to be employed as a means for the cure of deafness.

1465. F. A. and F. Calvert, Manchester, engineers. Improvements in machinery for burring, ginning, cleaning, and carding cotton and other fibrous substances.

1466. G. Davies, Serle-street, Lincoln's-inn, civil engineer. Improvements in the currying and finishing of leather. (A communication.)

1467. J. Place, Hoddlesden, spinner and manufacturer. An improved combination of materials to be employed for the purposes of sizing and stiffening.

1468. J. C. Wilson, 14A, Cannon-street, civil and mechanical engineer. Improvements in machinery for reducing cocoa-nut kernels and other substances to a state of pulp.

1469. J. C. Wilson, 14A, Cannon-street, civil and mechanical engineer. An improved machine for unhusking rice and other seeds.

1470. G. Bedson, Manchester, manager. Improvements in cupolas and blast furnaces.

1471. T. C. March, St. James's Palace, Westminster, gentleman. Improvements applicable to the ornamentation or decoration of articles of furniture, part of which improvements may also be applied for architectural ornamentation.

1472. T. H. Milner, Edinburgh, gentleman. Improvements in thrashing machines. (A communication.)

1473. R. Hughes, Worcester, road surveyor. An improved implement or apparatus for scraping and sweeping turnpike and other highways, carriage drives, and footwalks, or other places requiring to be so cleaned.

1474. H. S. Barron, Morant Cottage, Blackheath-road, Greenwich, engineer. Improvements in steam fire-engines, parts of which improvements are applicable to steam boilers, and to pumps generally.

1476. G. Davidson, Magie Moss, Aberdeen, paper manufacturer. Improvements in the manufacture of paper bags, and in the machinery employed therein.

1477. J. Jones, Manchester. Improvements in gas regulators.

Dated June 13, 1863.

1478. G. Davies, 1, Serle-street, Lincoln's-inn, civil engineer. An improved mode of oiling journals or axles. (A communication.)

1479. T. Wrigley, Bury, paper manufacturer. Improvements in machinery or apparatus for filtering or cleansing water or other fluids.

1480. J. Hopkinson, Manchester, mechanical engineer. Improvements in the mode of securing or fastening the ends of metal bands, and in machinery for preparing the same.

1481. W. N. Hutchinson, Plymouth, Major-General in Her Majesty's Army. Improvements in means of, and apparatus for, cleansing ships' bottoms and sides.

1483. T. A. Elliott, Enniskillen, civil engineer. Improvements in the construction of and in the means of ballasting ships and other vessels.

1486. M. B. Westhead, Manchester, manufacturer and merchant. Improvements in adapting tapes, ribbons, and other such narrow fabrics or thread to surfaces from which they may be unwound, or upon which they may be rewound.

1487. I. G. and W. Bass, Broughton Little, Cumberland, nail manufacturer. Improvements in the manufacture of nails and spikes.

1488. H. G. W. Wagstaff, Radnor-terrace, tallow melter. Improved apparatus for feeding steam boilers with water, which apparatus is also applicable for raising water.

1489. S. S. Robson, Hendon House, Sunderland. Improvements in apparatus for working the rudders of vessels, and in auxiliary steering apparatus.

1490. J. Shand, Upper Ground-street, Blackfriars-road. Improvements in the arrangement and construction of steam fire-engines, and in boilers for the same, such boilers being applicable to other purposes.

Dated June 15, 1863.

1493. T. Cope, Liverpool, tobacco manufacturer. Improvements in the construction of rocking-horses, and in giving additional motion thereto. (A communication.)

1494. H. B. Barlow, Manchester. Improvements in machinery for opening and cleaning cotton and other fibrous substances. (A communication.)

1495. I. B. Harris, Castle Mills, Fountain-bridge, Edinburgh. Improvements in the manufacture of flexible and other tubes.

1496. J. Juckes, jun., 1, Armaught-road, Roman-road, Old Ford. Improvements in furnaces.

1499. W. Clark, 53, Chancery-lane, engineer. Certain improvements in engines for obtaining motive power from steam or other liquids, also partly applicable to pumps. (A communication.)

1500. P. P. L. Stafford, St. James's-square, Captain in Her Majesty's Indian Army. Improvements in firearms.

Dated June 16, 1862.

1501. J. J. Shedlock, Vincent-street, Westminster, gas engineer. Improvements in valves for the passage of steam, gas, and fluids.

1503. W. Manwaring, Banbury, engineer. Improvements in harvesting machines.

1505. J. Lightfoot, Accrington, chemist. Improvements in fixing mordants in the processes of dyeing and printing textile fabrics or yarns.

1506. J. G. Jennings, Palace-road, Lambeth, sanitary engineer, and M. L. J. Lavater, Bath-street, Newgate-street, rubber manufacturer. Improvements in moulding and vulcanizing articles of india rubber.

1507. W. Score, 30, St. Paul's-road, Camden-town, chemist. Improvements in the manufacture of candles and soap.

1509. A. J. Fraser, Water-lane, Great Tower-street. Improvements in apparatus applied to house and carriage window sashes for the working and fastening thereof.

1510. W. Neill, jun., Bold, near St. Helen's, engineer. Improvements in steam engines.

1511. J. C. Onion, Birmingham, smiths' bellows and patent portable forge manufacturer. Improvements in smiths' and other bellows.

1512. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in protecting or preserving the silvering or quicking on glass, and in the manufacture of glass vessels for silvering or quicking. (A communication.)

Dated June 17, 1863.

1513. W. H. Dawes, Bromford Iron Works, West Bromwich, Stafford, ironmaster. Improvements in the manufacture of iron.

1514. J. Banwell, Watling, Oxford. A combined machine for collecting and placing in rows, or collecting and elevating into a waggon or elsewhere hay, corn, or other agricultural produce.

1515. J. Mills, Sunderland, cordwainer. Improvements in the square rigging of vessels.

1516. J. Newnam, Crayford, Kent, sugar refiner. Improved means of, and apparatus for, boiling in vacuo at a low temperature.

1517. J. F. Spencer, consulting engineer, Newcastle-on-Tyne. Improvements in steam, gas, and water-tube joints.

1521. T. Purdie, 314, Oxford-street. Improvements in the plastering, colouring, and decoration of walls and ceilings.

1523. W. Naylor, Queen's-road, Dalston, engineer. Improvements in apparatus for compressing, holding, and regulating the pressure of gas.

Dated June 18, 1863.

1524. J. A. Sparling, Upper Hornsey-rise, gentleman. Improvements in twisting and winding silk, and in the machinery or apparatus to be employed therein.

1530. R. Jobson, Dudley, Worcester. Improvements in machinery for making moulds to be employed when casting metal.

Dated June 19, 1863.

1532. H. Reynolds, Fleet-street, gentleman. An improved method of rendering atmospheric air fit for illuminating purposes, and of increasing the illuminating power of inflammable gas.

1538. A. Morel, Roubaix, manufacturer. Improvements in traction engines.

1542. M. Henry, 84, Fleet-street. Improvements in decorticating grain and seeds, and in the application of the products obtained by, and materials used in, decorticating. (A communication.)

Dated June 20, 1863.

1546. G. Haseltine, 12, Southampton-buildings, Chancery-lane, civil engineer. An improved oil, more especially designed for mixing paints and colours, and new mode of manufacturing the same. (A communication.)

1550. C. Peterson, Newport, Isle of Wight. A new material or compound applicable to the manufacture of pipes or tubes, to caulking or covering ship's bottoms, and to other useful purposes.

1552. H. Macaulay, Rotherham. Improvements in covers or appliances for the rims, borders, or top edges of chamber utensils, applicable also to commodes and water-closets.

1554. A. T. N. Goll, Caledonian-road, jeweller. Improvements in the manufacture of mountings or settings for precious or other stones.

1556. W. L. and T. Winans, Baltimore, United States, gentlemen. Improvements in couplings for propelling shafts of ships or vessels.

1558. W. L. and T. Winans, Baltimore, United States, gentlemen. Improvements in adapting propellers for propelling ships or vessels for ocean navigation.

Dated June 22, 1863.

1564. J. McLean, Dander Hall, West Calder, North Britain, chemist. Improvements in treating oil from shale or other bituminous minerals and similar oils to obtain various products therefrom, and in apparatus therefor.

1568. W. Rowan, Belfast, engineer. Improvements in pistons.

1570. W. L. and T. Winans, Baltimore, United States, gentlemen. Improvements in adapting propellers for propelling ships.

1572. W. L. and T. Winans, Baltimore, United States, gentlemen. Improvements in the construction or arrangement of the working parts of engines for actuating the propelling shafts of steam vessels.

1574. C. T. Burgess, Gower-street. Improvements in reaping machines.

Dated June 23, 1863.

1580. T. F. Parsons, chemist, Maindee, Monmouth. Certain improvements in the mode or modes of preparing plates, bars, or other objects of iron for being coated with metal or alloys.

1582. W. L. and T. Winans, Baltimore, United States, gentlemen. Improvements in steam boilers.

1584. W. L. and T. Winans, Baltimore, United States, gentlemen. Improvements in the arrangement of apparatus for superheating steam in steam boilers.

1586. A. Mien, Hope Iron Works, Station-street, Stratford. Improvements in apparatus for generating steam.

1588. W. Toovey, 3, Rue de la Pompe, Brussels, lithographic printer. Improvements in photolithography, photozincography, and photographic engraving on copper or steel plates, or on any other suitable substances.

Dated June 24, 1863.

1594. J. L. Hughes, Leek-road, near Joiner-square, Hanley, Staffordshire. Improvements in ornamenting porcelain.

1596. A. E. Brae, Leeds. Improvements in apparatus for actuating domestic bells and other signals by the electric current.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated June 25, 1863.

1599. D. Hussey, Nashua, New Hampshire. Having reference to bobbins and the winding of roving or yarn thereon.

LIST OF SEALED PATENTS.

Sealed July 3, 1863.

13. F. C. Bakewell.	72. C. Worssam.
48. E. V. Gardner.	79. E. T. Hughes.
49. J. G. Dahlke.	87. R. Lilthy.
65. J. H. Johnson.	101. J. Fenby.
69. C. Allen.	135. L. P. Josse.
70. R. T. Monteith.	216. W. Mellor.

Sealed July 7, 1863.

75. C. E. Gray.	390. C. and D. Faulkner, J. Fairley, and W. C. Stiff.
103. D. and J. Tannahill.	913. H. W. Ripley.
105. J. T. Stroud.	283. W. E. Newton.
123. E. Morewood.	1043. A. V. Newton.
203. T. Lambert.	1060. J. and W. Marris.
252. F. W. Wymer.	1075. J. Rowley.
271. C. H. G. Williams.	1125. W. C. Wilkins.
272. A. Pritchard.	1137. A. V. Newton.
288. F. Tolhausen.	

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, July 7, 1863.

490. J. D. and A. P. Welch. Blocking and pressing hats and bonnets.

492. T. R. Harding. Carding and combing flax, wool' cotton, and other fibrous substances.

503. J. W. Burton. Bearings and bushes of axles and bushes of axles and shafts.

509. G. A. Huddart. Imparting heat to fluids.

519. R. A. Brooman. Lamps for burning petroleum and other similar oils, and in feeders or cans for supplying oils to such lamps. (A communication.)

524. B. Lawrence and W. Niblett. Regulating the flow of gas for purposes of illumination.

533. A. Macivor. Veneering or overlaying woods.

534. G. Tomkins. Manufacture of tin and terne plates, and in apparatus to be employed therein.

537. C. Ritchie. Machine for making spiral lighters or spills from wood or other substance.

541. A. P. Price. Blue colours. (A communication.)

545. M. Puddefoot. Implements for tilling and cultivating land.

547. R. J. Nodder. Hats, caps, helmets, military head-dresses, &c.

549. J. H. Albinson and H. H. Cocker. Spinning, doubling, throwing, and reeling silk, and the machinery employed therein.

550. W. Staufen. Fibrous substitute for human and other hair.

553. J. Carver. Arrangement or fixing of combs in machines employed in the manufacture of bobbin net or twist lace.

554. J. A. Coffey. Controlling and facilitating locomotion, whether on land or on water.

557. A. Dudgeon, G. F. L. Meakin, and E. E. Allen. Underground railways or subways, and carriages to be used or worked therein.

560. V. D. Delahaye. Cleaving and excavating pit coal and rock or earth.

561. J. H. Johnson. Machinery or apparatus employed in the preparation or treatment of hemp and other textile materials. (A communication.)

562. B. West. Metallic pens.

568. S. Williamson. Construction of furnaces.

570. E. Paine. Apparatus for facilitating the cleaning of vessels' bottoms while afloat.

571. T. E. Symonds. Screw-propelled ships, and the arrangement and mode of disconnecting, withdrawing, and lifting screw propellers.

574. E. Hayes. Supply water to surface condensers of marine engines.

575. S. Bateman. Manufacture of wire rope and cordage, and the machinery employed therein.

580. A. F. Pagny. Agricultural implement for cultivating tubercles, roots, and all oil plants.

581. G. Hawksley and T. Bissell. Powder chargers.

584. C. Garton. Improved method of applying heat in the manufacture and refining of sugar, and in malting, hop drying, brewing, distilling, and vinegar-making.

599. B. S. Cohen. Apparatus for protecting the points of pencils.

630. C. Clay. Chain harrows.

639. D. W. Ransom. Fixing artificial teeth.

647. J. Cowley. Manufacturing bricks, tiles, pipes, and mouldings.

651. C. H. Lea. Apparatus for opening and closing the gates of railway crossings, which apparatus also acts simultaneously upon the signals.

653. P. Hugon. Obtaining and applying motive power.

668. A. Barclay. Locomotive boring and winding engines.

669. A. Barclay. Traction engines, and apparatus for indicating the pressure of steam.

679. J. Polkinghorne. Treating tin ores, and apparatus for treating ores and matters containing arsenic.

697. W. Young. Type-composing and distributing machines.

703. W. E. Newton. Manufacture of iron and steel. (A communication.)

730. F. Norrington. Girths or bands and knee-caps for horses.

761. W. Clark. Separation or obtaining of ammonia pomazoted matters, and the preparation of manure. (A communication.)

808. B. W. Goode. Journal axle or bearing, particularly applicable to rolls.

821. W. E. Newton. Producing yellow colouring matters and other colours which may be derived therefrom. (A communication.)

842. G. T. Bousfield. Steam boilers. (A communication.)

1163. W. E. Gedge. Manufacture of paper stuff or pulp from certain vegetable substances. (A communication.)

1311. E. Hunt. Posts or pillars for fences and gates. (A communication.)

1361. S. Bates and J. Jardine. Carriages used in manufacture of lace or other fabrics.

1367. L. S. Chichester. Drying grain.

1413. W. C. Brocklehurst, J. Creighton, C. Mankinson, and J. Creighton. Apparatus for winding yarns or threads.

1439. H. Bessemer. Construction of and mode of working hydrostatic presses and hydraulic apparatus.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

1593. H. H. Bishop.	1631. W. F. Thomas.
1594. J. A. Salmon.	1633. B. Lambert.
1609. J. Morris.	1636. B. Mitchell.
1613. W. Skinner.	1640. J. Leslie.
1628. W. Hood.	1660. F. C. Warlich.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

1531. E. Rogers and H. Mackworth.	1586. R. Shaw.
1578. J. Lewtas and J. Humphreys, jun.	1597. E. C. Healey and E. L. Allen.
	1683. L. Blackstone.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SPECIFICATIONS PUBLISHED

For the Week ending July 4, 1863.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JULY 17, 1863.

RAILWAY ACCIDENTS.

MR. BENTINCK, by a mental saltation of the strangest kind, has arrived at the conclusion that railway accidents are altogether due to high speed; and having done so, he at once proceeds to enforce his views in the House of Commons. The honourable member's speech, delivered on Friday night, is a remarkable instance of that style of argument which, commencing on false premises, regards individual opinions as proved facts, and gradually leads to the most erroneous conclusions. Not content with the simple statement, conveyed in other words, that speed and danger were nearly synonymous terms, he put all doubt at rest as to what the proper definition of high speed is, by stating that thirty miles an hour was the maximum, to which Government should confine the speed of our trains. "Experience is the foundation of all knowledge," says Bacon. Whether Mr. Bentinck ever read or heard this proposition we do not pretend to say. It is certain that if he has, he has quite forgotten it in these latter days; for all experience goes to show, in such a way too that those who run may read, that the largest proportion of accidents occur to trains which both receive and deserve the epithet "slow" in the fullest sense of the term.

There is but one special casualty to which fast trains are exposed as a consequence o. their speed; that is simply derailment. It may occur from a broken rail, a defective chair, a fractured tyre, or, perhaps more rarely, from an axle giving way. As to collisions of every description, it follows, from the nature of the case, that slow trains are just as much exposed to the chances of such a calamity, as those which are called "express." It is easy enough to see that because a fast train runs into one slower, the circumstance is just as much a result of the tardiness of the one, as of the acceleration of the other. We need not proceed further with this line of argument; every one who has given the matter anything like a little careful study, must be aware that all other accidents, save the one speciality we have mentioned, occur alike to all sorts of trains, fast or slow, goods or express.

Mr. Bentinck's supporters urge, however, that trains leave the rails without anything giving way either in the engines, carriages, or permanent way; that they run off the track, in fact, simply because of the speed, and consequent oscillation of the locomotive, &c., due to the imperfections of the permanent way or the faulty construction of the machine. This is mere assertion, and has little foundation in fact. Not only is it not true that express trains leave the rails more frequently than those which proceed at thirty miles an hour; but it is even more than doubtful that a train ever leaves the rails while things remain in their normal condition. An accident, in the full sense of the expression, is generally attended by such dire destruction, that it is a matter of the most extreme difficulty to determine what was broken or displaced before, and what after, the derailment; and while the warmest defenders of such a proposition must admit that the matter, with a few rare exceptions, is clouded by the mists of uncertainty, we state that all mechanical science and experience, employed synthetically or analytically for the purpose of argument, go to show that a high speed, or, at least, what is called a high speed, is not in itself a sufficient cause to lead directly to derailment. Nevertheless, we admit that the higher the speed, the more likely is it that a locomotive, oscillating violently, may force out a defective chair, or break an over-worked tyre. An accident would follow of course; but even then such a result is due not so much to the speed of the train, as to the defect in the road or the tyre, and that negligence or parsimony which permits such a state of things to exist.

But quitting theoretical argument, let us simply consider that railway statistics prove that express trains, so far from being the most dangerous, are the safest, simply because the greatest possible care is exerted that they shall not be exposed to a class of accidents with which speed has nothing whatever to do. The promoters of a proposal for Government intervention, in questions of speed, signally fail in making their arguments good in the face of such facts.

It seems pretty clearly proved—and that too, alas! by practical demonstrations so lamentable as to rank almost as national calamities—that the speed proposed by Mr. Bentinck, or even one a dozen miles an hour less, is to the full as dangerous as one twice as great. At all events quite as many deaths, and as great a destruction of property have resulted from the one as the other. The question of danger in railway travelling lies too deep for superficial observation, or hasty legislation to reach it.

At one period or another in the history of this strange old England of ours, sumptuary laws ruled paramount, and bore sway over the lieges of the different Sacred Majesties who have sat on the throne, and very difficult to carry out and enforce were these laws—so troublesome, indeed, that very frequently both people and sovereign, voted them a nuisance. And such would we quickly find any sumptuary bill—for such it properly would be—which made thirty miles an hour a maximum pace. So far from railway directors being anxious to increase speed, they hail with delight any means by which it can be reduced without a proportionate loss of public favour. They well know that a permanent way which will easily carry the light locomotive which suffices for slow speed, soon gives way under the tread of the giant racers, which whirl an express to its destination; and a law which removed responsibility, by reducing speed, could not fail to be mischievous to a degree which its promoters little imagine. It would lead to a negligence in the management of traffic, in the condition of the road, in the state of repair of the rolling stock, which would very quickly render a second bill limiting speed to ten miles an hour, necessary to the safety of tha general public. If any bill is ever passed by Government which will have the regulation of railway speed for its object (and we trust our rulers are too sensible to do anything half so foolish), let it be to enforce an increase in speed; such a course would compel such a remodelling of our system, as would secure as much safety at eighty or ninety miles an hour, as we now enjoy at forty or fifty.

Mr. Gibson might well remark that "speed was a relative term." We believe that miles and miles of track may at this moment be found in England, over which a train might be run with safety at 70 or 80 miles an hour, were it possible for an ordinary locomotive of not more than 40 tons weight to attain such a velocity. We also believe (and tremble), that a large proportion of our permanent way, and a great deal of our rolling stock, is quite unfitted for a speed greater than 25 or 30 miles in the same time; and no legislation could be more absurd than that which would pretend to regulate all speed alike, without regard to such facts. There exists no earthly reason whatever, for keeping a track in first-rate order now, but the one—namely, that trains may proceed over it at high speeds with safety. To express speeds, and to these alone, are we to look for the cause of that vigilance, energy, liberality, and attention to minute matters of detail, on which immunity from accidents really depends. Remove this stimulus, and the entire moral standard—if we may use the phrase, of our railway system—will become depreciated, and instead of matters being improved they will be made very much worse. The statistics of the last few years show that, although the number of passengers carried has increased, the number of the deaths by accident is considerably diminished. Thus Mr. Gibson's statement went to show that: In 1861 there were 56 accidents, resulting in the death of 46 passengers, and injuries to 780; in 1862 there were only 52 accidents, with 24 deaths and 537 injuries of passengers. In 1861 the number of passengers carried by railways was 173,000,000. For 1862 he had not the exact returns, but he thought the number carried might be taken at 183,000,000. For the first half of the present year there had been 16 accidents, with 4 deaths of passengers and 165 injuries. Such results demonstrate in the clearest possible manner that Government interference after the fashion proposed by Mr. Bentinck is unnecessary, because growing intelligence, increased knowledge, and, above all, that efficient supervision which directors begin to discover is the only means of avoiding enormous losses, daily strengthens those elements of safety on which alone our security can depend.

The usual definition of the word "accident" implies that it is "an unforseen event," something occurring fortuitously. All the casualties to which railway trains are liable, may be classed under two heads—those to which the term "accident" in the above sense is applicable, and those to which it is not. Thus, a tyre breaking, an engine exploding, a train catching fire, are, as a general rule, accidents in the fullest sense of the term; but collisions of every kind are so obviously the result of some breach of the traffic regulations, that they might often be foretold and calculated on with great ease, long before their occurrence. If a time table is properly drawn up and rigidly observed, it is impossible that two trains can run the one into the other. The observance of these rules in the most perfect manner is, however, an impossibility, and signals are provided to confer those conditions of safety which arbitrary regulations cannot supply. The greater the departure from the times laid down by a traffic superintendent for the arrival and despatch of trains, the greater the work and responsibility thrown on signals and signal-men; and it is not difficult to see that want of punctuality may become so great, that no system of signals invented or worked by fallible man can possibly provide for every contingency. We know what follows.

Railway companies are wisely permitted to draw up their own laws; and, generally speaking, these laws are good and sufficient, and their accurate observance would secure the greatest amount of safety. But railway men know very well that good signalling will permit a certain latitude in the observance of their laws, and directors are, in consequence, prone to gamble with the lives of passengers, and their own property; well knowing that if a

thousand excursion or other trains, despatched without any regard to the conditions of safety, arrive in good preservation at their destination, they will pay for an accident to the thousand-and-first. Here, then, we find the true field for Government interference. Let Parliament so legislate, that while railway companies may regulate their speeds and lay down their own times for departure and arrival, they shall also be compelled, by a proper supervision, to observe these times as far as the capabilities of the locomotives will admit. Trains should leave the termini punctually, and might very easily be compelled to arrive at principal stations with sufficient conformity to time tables to prevent accident. Locomotives would not be overworked; more regular speeds would be maintained; and the comfort, as well as the safety and convenience of the public, would be secured to an extent which, we feel certain, would be so obvious, that such legislation, instead of being considered a vexatious burden, would be pronounced a positive boon.

THE METRICAL SYSTEM.

On the 1st of this month, Mr. Ewart's Bill for decimalizing the existing system of weights and measures and establishing an accordance between them and those of other countries, was read a second time in the House, by a majority of 110 to 75. Now, although we look upon this Bill as in many respects a somewhat crude production, we nevertheless hail its second reading with some satisfaction; as an evidence that the *vis inertiæ* exerted by the British mind when urged towards any new course, is being overcome with regard to this measure. We may therefore hope that the collective wisdom of the nation has stamped its approval on the general principle of the Bill, although we should be sorry to see the House of Commons affirm its details in their entirety, and thrust the measure on the country without further consideration. Anything, however, that will relieve us from the present extravagantly absurd system would be acceptable. We fancy ourselves the practical and common-sense nation *par excellence;* but in what other country on earth are there different weights and measures for almost every different trade; and where else do weights and measures—nominally the same—vary in separate districts of the same kingdom? An enumeration of the different weights, measures, and coins used in Great Britain and Ireland, and our dependencies, would fill a volume, while the useless and chaotic nomenclature would perplex the clearest understanding. Newton, in order to avoid the confusion resulting from English measures, was accustomed to use the old French *toise* or *hexapeda*.

The decimalization of weights, measures, and coins has simply in view the bringing of our common means of estimating the value of material substances under the dominion of our ordinary system of notation; it is merely the complementary result of this system. Had we space we could show—what must be evident on reflection to every arithmetician—that the much-vaunted decimal system of notation is much inferior to the duodecimal system. The importance, however, of universally using the habitual system of arithmetical computation—whatever that system may be—is such, that the decimal system of weights has been adopted for some time in the Mint, the Bank of England, and the Post-office. The grain computed decimally is employed by men of science; the decimal foot has been used for some years by Mr. Whitworth; and English makers of the exact scales used for scientific purposes, generally furnish the kilogramme and its subdivisions in addition to the ordinary weights.

There are, however, several objections to Mr. Ewart's Bill. Leaving out the fact that it is a compulsory measure, and regarding it from a scientific point of view only, we find, first of all, that it leaves the decimal coinage question untouched, and, secondly, that it is based upon the French metrical standard.

A partial decimalization of our usual means of estimating the values of material substances would be a most incomplete proceeding, and in many cases its action would be worse than useless. This was very plainly demonstrated in Lord Overstone's report on the decimal coinage, and it would exceed our limits to follow his reasoning.

The objections we have against the French metre system are by no means founded on an anachronistic sentiment of nationality. There is, in fact, no ground for such a feeling. Although England did not respond to the letter written by Louis XVI., at the request of the National Assembly (1790), inviting the formation of a joint commission of members of the Royal Society and of the Academy of Sciences, to determine the unit of the metre, other countries besides France were represented in the proceedings of the Academy of Sciences. Most of the nations who now use the metre helped to determine its fundamental unit; and the representatives of Spain, Italy, the Netherlands, Denmark, and Switzerland took part in the labours of the Academy of Sciences to accomplish the purpose of the National Assembly. Unfortunately, however, the French and the other commissioners seem to have devoted more attention to the Opera and to politics than to the work they had in hand. It was intended that the ten-millionth part of a quarter of the meridian should be the unit of linear measure; but the commission adopted a standard of length which is only *about* the ten-millionth part of a quarter of the meridian. Now, the quarter of the meridian, as found by Mr. Encke—upon whose calculations are based the labours of the English Ordnance Survey—equals ten million times the metre, *plus* 856 metres. The French metre would thus require a correction of about eight-hundredths of a millimetre.

As the kilogramme is the weight of distilled water at the point of freezing, measured by a cubic decimetre, any change in the linear measure would require an alteration in the official unit of weights. A change in the decimetre, as it must bear upon the three dimensions in the cubic decimetre, would modify the kilogramme three times as much as the metric measure of the cubic decimetre. Thus, if the meridian of Encke, of 10,000,856 metres, be taken as the standard, the kilogramme would have to be increased by no less than 257 milligrammes.

The occurrence of this unfortunate mistake of the International Commission of 1791 has, of course, been ascertained long ago in this country; but, according to a communication from Monsieur Babinet, the well-known member of the *Institut*, lately addressed to one of our foreign contemporaries, the state of things is much worse than was generally believed. He considers it very doubtful whether the kilogramme of the Archives—the official kilogramme for the whole world—is really the exact weight of a volume of water equal to the cubic decimetre of the standard metre in the Archives. Most of the work in the determination of the standards was executed by the instrument-maker Fortin, whom M. Babinet scarcely considers as equal to the task. As to Lefèvre-Gineau, who was charged with Fortin to determine the kilogramme, he actually pierced with a small hole the hollow cylinder which was to give a determinate number of grammes, "in order that the air in the interior should be in equilibrium with that at the outside!"

It would be evidently impossible to rectify any mistake without causing a most deplorable confusion, particularly in the countries now using the French system; but it must never be forgotten that the kilogramme is only approximatively the weight of a cubic decimetre. All physicists must wish for a new and exact comparison between the metre and the kilogramme; and until that takes place there is no certainty that a given volume of a substance, whose specific weight is known, has a given weight in grammes; and *vice versâ*. It is said that the eminent Laplace was extremely anxious, during the last years of his life, about the probable disagreement between the metre and the kilogramme. M. Babinet also states that he has seen the *procès-verbaux*—sold as waste paper—of the Metric Commission, and there was nothing about them that showed a careful elaboration of the question. According to Mr. T. Q. Adams' Report to Congress on Weights and Measures (Washington, 1821), it would appear that the International Committee adopted as a second natural standard the pendulum vibrating seconds at the 45th degree of latitude. Mons. Babinet seems to be ignorant of this fact; for he insists on the importance of ascertaining the exact deviation of the metre from the meridional standard, in case the standard metre in the Archives should unfortunately happen to be destroyed.

The *soi-disant* practical men, Messrs. Henley and Hubbard, who opposed Mr. Ewart's Bill, did not allude to these objections. It is absurd to say, with the former gentleman, that "though the country was asked to adopt the French system, it was not to take the French measure, but decimal parts of an inch, which were to be compared with the French unit." This assertion only finds its parallel in his statement, that "the world was continually growing," and that the measure of the unit would be thus lost. Mr. Hubbard also was mistaken in his supposition that the introduction of the French metrical system would cause great inconvenience to the working classes. It is within our own knowledge that the metrical system is largely in use in the Lancashire engineering workshops. In the specification of many foreign orders, the dimensions are often marked in metres, and it is thus easier to work with the metre than to translate the dimensions into English measures. Giffard's injectors are made by Sharp, Stewart, and Co. to the metric system of measures, and the workmen adapt themselves with the greatest ease to the metre and its decimal parts. Instead of the vague "one-sixteenth full," or "one-sixteenth bare," too often to be seen written on the full-size drawings of even first-class establishments, a neat decimal figure shows the exact limit required for a true fit. But few good workmen are of the opinion of a certain engineer of our acquaintance, who, on being asked which measure he most referred, replied that he liked best the one used in the States, "because it was the same as the English foot."

Leaving aside the disastrous mistakes made in determining the French standard, the metric system, as compared with our own, is simplicity itself. A French engineer, in working out any measurements, has merely to deal with the metre. Its multiples are designated by simply preferring the specific terms for 10, 100, 1,000, &c., taken from the Greek, whilst the decimal submultiples are shown by similar prefixes taken from the Latin. English en-

gineers have to reckon in inches, feet, yards, fathoms, poles, furlongs, and miles; the respective proportions of which are 12, 3, 2, 2¾, 40, 8! We again find that the mechanical engineer takes the foot, the civil engineer the yard, the mining engineer the fathom. Some mechanical engineers divide the foot decimally, others use barleycorns or twelfths of the inch, while the majority use sixteenths of the inch. Many civil engineers have adopted the acre as a unit, with decimal divisions of that unit. With regard to the fathom, there are three different lengths going under this name, the 6 ft. fathom of a man-of-war, the 5½ ft. fathom of a merchant vessel, and the 5 ft. fathom of a fishing smack. Such partial systems as that of Mr. Whitworth, who takes the foot as a unit; or the proceeding recommended by Mr. J. Simon Holland,* that of having the sixteenth of an inch as a basis, would, in course of time, only make the present confusion worse confused, and leave us in a worse state than we now are. What is wanted is a sound comprehensive measure, of universal application; and the first throes that generally attend the introduction of any novelty, being once overcome, the question will then be settled for ever. While deprecating a servile copying of the French system, or rather of the French standard, we would, nevertheless, urge upon our legislature the speedy adoption of decimal weights, measures, and coinages. Like every innovation it will, doubtless, cause some hardship to individuals—*e.g.*, separate old patterns of machinery could be seldom used in a new arrangement calculated to the metre; many valuable scientific publications would be greatly depreciated by an introduction of a new system of weights and measures; some of the useful formulæ and numbers committed to memory by most engineers would have to be unlearnt. The law would, however, be a national advantage—indeed a universal benefit; for North America and Russia, who now use our foot measure, would then assuredly employ our metre.

STEAM FIRE-ENGINE COMPETITION.

Now that the excitement attending a public competition has settled down into something like calm reflection, we can consider in its proper light the actual bearing of the memorable trial which has taken place—a trial, the importance of which can hardly be over estimated. For more than a century steam machinery has received an attention which nothing else in the department of scientific engineering can parallel. The consideration of every fact, every theory, connected with it, has been so exhaustive, that in England, at least, the assertion that we had nothing more to learn or to teach would seem fraught with truth, yet, after all, such is not the case. The careful observer is well aware that, although steam machinery performs its office passably well on land and ocean, much remains to be accomplished, much to be learned; and the three days' trial of steam fire-engines at Sydenham has added another and most valuable chapter to the records of steam power.

It is, perhaps, scarcely possible to imagine a situation more trying than that to which machinery is exposed at a large fire. Circumstances preclude, to a great extent, anything like system in its management. All its powers are certain to be taxed to the uttermost, without consideration for consequences. Those who ought to be most careful and steady, unavoidably become participators in the overwhelming excitement of the moment; and both the materials and workmanship of a steam fire-engine, are exposed to tests such as few other forms of machinery ever encounter. A competition, such as the last, may not, perhaps, present the same stimulus to exertion as a fire; still it is not too much to say that the engines which passed scatheless through that ordeal, are capable of meeting most of the exigencies to which they may be in future exposed in the fulfilment of their legitimate duties.

Important as the results have been, they yet leave much to be learned. The experiment has been far more a test, to a certain extent, of the "staying" powers of the machines, than of their actual capabilities. It has proved that a particular class of machinery can be worked to the uttermost, for a certain period of time, without breaking down. It has proved the relative merits of a few different machines under certain circumstances; but it has neither been a test of the relative powers of those machines under *all* circumstances; nor of their capabilities for that long sustained exertion, which we have little doubt they will be frequently called on to make. Nevertheless, the competition has been of the utmost value, just as a single torch is in a vast cavern—it enables us to find a path of escape from a thousand difficulties; and the warmest thanks, not only of engineers, but of the whole community, are due to those gentlemen who formed the Committee, and cheerfully contributed both time and money to an undertaking which cannot fail to be productive of the most valuable results.

We trust, however, that the experiments of the week before last, are but the forerunners of a far more extended and valuable competition. As being the first thing, virtually, of its kind, we could pass in silence over those items in which it is found wanting, were it not that they are eminently suggestive. Failures are more instructive than successes; and although we do not for a moment denominate that which is over, by such a phrase, still its defects point out in a most valuable light what ought to be done in future. The actual quantity of water lodged in the proper place may be a measure of the utility of a fire-engine, but only to a very limited extent. Our readers may rest assured that such a test is, as a general rule, far more a measure of the capabilities of the fireman, of the qualities of hose or jet pipes, and the state of the weather, than it is of the powers of an engine. The trial, by delivering into hoods placed at a considerable height, is so valuable, that it should be on no account omitted; but various other tests should at future trials receive a greater prominence than they have hitherto done. We desire to see steam fire-engines tested for many hours together, not for many minutes; the quantities of water passed through them accurately measured, as well as that delivered at 20 or 30 yards from the delivery nozzle; the actual amount of useful effect, compared carefully with the entire developed power of the machine, not because the consumption of fuel is a matter of any importance, but because the wear-and-tear of necessarily light machinery is, and we may rest assured that every pound of coal consumed unnecessarily is a source of destruction, which should be, as far as possible, obviated by better arrangements. The quantity of water evaporated to perform a certain amount of work is a question of considerable importance. The difference in construction and speeds of the different pumps, and the quantity passed through them, is deserving of attention and comment. Competitions of the kind are not merely intended to bear a passing interest, and afford a momentary stimulus to exertion; their principal value must reside in the instruction to be derived from them as to the relative working, not only of different machines, but of every separate part of each machine. It is of little importance that steam performs its duty well, if the pumps are found wanting, and *vice versa*. The necessary data no trial which has yet taken place can supply, and therefore we trust that no great space of time will elapse until another and far more valuable competition takes place.

Any future improvements must find their development in design. We do not imagine that workmanship can do more. As a general rule, that displayed by the exhibited engines was first-rate, and could not be excelled in the first factories of the kingdom. It has been lately the custom, amongst a certain class, to deprecate the advantages of finish; but we unhesitatingly assert that to it may we trace all that marvellous perfection which causes our machinery to rank so highly in the estimation of the world. We believe that to it, can alone be attributed the endurance displayed by the competing engines during a trial which tested machinery as we never saw it tested before. We would hint to our own engineers that they have something yet to learn from their American brethren, whose brass and copper work is marvellous in its beauty and finish.

At the past trial, a certain amount of confusion was manifest. Perhaps, under all the circumstances, it was unavoidable. We suggest that, in future, not more than one or two engines be tested at a time. The amount of continuous work done in various ways during twelve hours, would afford experience of the most valuable kind; and although it may occupy more time, we doubt if it would, after all, give more trouble to a committee than the present system of trying all the engines of a class at once. A trial has been carefully conducted at Manchester within the last few days, a notice of which will be found elsewhere in our columns. It will be evident from its perusal that the quantity of water delivered into a hood is no accurate measure whatever of the powers of either engine or pump; and until a trial is conducted on somewhat similar principles, we must be content to remain in ignorance as to a thousand little matters of the greatest importance. One important and undecided question we will point out:—We possess no data whatever to show what engine filled its pumps and what engine did not, since the quantity of water passed through them was not measured; yet the pumps were of every variety and worked at every speed. We have no fault to find with what has been done; the results obtained are extremely valuable; all we require is their extension in future.

Our advertising columns prove that American engineers are determined not to permit matters to remain as they are, and we trust that English engineers will not permit the challenge to pass wholly unnoticed.

ROYAL AGRICULTURAL SOCIETY.

(From our Special Correspondent.)

THE MEETING AT WORCESTER.

THE fair and ancient city of Worcester—the scene in days of yore of many stirring episodes in our history—is at present enlivened by the great meeting between agriculturists and engineers perennially held under the auspices of the Royal Agricultural Society. Worcester appears to be one of the pleasantest places in England; handsomely built and well paved and lighted, with very regular and fine streets, the city itself is surrounded by a singularly beautiful neighbourhood, delightfully diversified with richly-wooded

* Vide MECHANICS' MAGAZINE, Vol. LXV., pp. 392, 415, 461, 564; and Vol. LXVII., pp. 176, 444, 495.

hills and dales. "The faithful city," as it is popularly called; from its motto, "*civitas in bello et in pace fidelis*," granted by that merry but somewhat improper monarch—Charles II.—is still constant to its old reputation for pleasantness; even when, as now, the theatre of a peaceful but bustling warfare between rival agricultural engineers. The scene of Cromwell's "crowning mercy"—as he called the battle of Worcester—no longer resounds to the din of a destructive intestine warfare; and *his* stern "Ironsides" are now superseded by iron embodiments of a very different description.

From its central situation, this handsome city is very well chosen for the purposes of the meeting; a slight drawback is perhaps its proximity to the town of Warwick, where the Royal Agricultural show took place such a short time ago as the year 1859.

The show-ground is about forty-one acres in extent—thirty-one acres of which belong to Battenhall Farm, while the remainder is in the occupation of Mr. Peter Foxwell. Besides the show-ground there are different other pieces of land for the trials. These consist of ten acres of grass, thirteen acres of land, besides two other pieces of fifty acres each. All these lands are of various qualities to meet the different kinds of trials of implements. All the works on the show-ground, have been entrusted to the gentleman who acted as contractor in a similar capacity at Battersea, last year. The directors of the West Midland Railway have carried out a branch line to Battenhall, for the convenience of the show, which is, however, not much farther than a mile from the centre of the city. The ground is very uneven and hilly, but what it loses in this respect it regains in the picturesque. The number of the implements exhibited (5,375) and of the exhibitors' stands (330) is rather high, although two of the larger makers are absent—the two Suffolk firms of Messrs. Ransomes and Sims of Ipswich, and Garret and Son of Leiston. The attractions of the Agricultural Show just now being held in Hamburg are probably too strong for those firms.

The weather on Wednesday was splendid, and a light breeze relieved the heat of the sun. The Agricultural Derby seems likely to be more fortunate this year, as regards weather, than its prototype of the turf, the London Derby, that great day for Cockneys. On entering, we perceived one of the steam horses, then being strenuously plied with coal and oil in its race for the prize "for the lowest consumption of fuel"—the "blue riband" of agricultural engineering. It was a fixed engine belonging to Messrs. Clayton and Shuttleworth, of Lincoln; the priority of its trial was due to that firm's name having been first drawn forth in a trial by lot. The somewhat delusive and uncertain nature of the trial of a *stationary* engine on the open field, was evidenced in the rocking motion the whole structure was undergoing from the absence of a foundation, with proper attachments. Great experimental investigations have shown long ago that a considerable amount of power is lost when an engine or machine is subjected to vibration.

The trials are conducted upon exactly the same system as at Chester in 1858, the last time that portable and fixed steam-engines were tried by the Royal Agricultural Society. Five years' reflection might have improved plans that are open to many and varied objections.

The usual quadrennial course of trials was broken into last year at Battersea, as neither engines nor implements were put to competition. Steam ploughs have been latterly tried every year; being treated as a new implement apart from the usual classification; and a special prize has been annually awarded to this kind of implement since its first appearance at the shows—the Battersea year excepted. These are the most interesting trials, from their comparatively novel character, and we hope to give a full account of them next week. No less than eleven different firms exhibit in this line—viz., Messrs. Smith (Woolston), Turner, Beards, Howard, Savory, Hayes, Fisken, Coleman, Fowler, Steevens, and lastly Mr. Williams.

In the course of our necessarily cursory and hasty examination, we could not perceive any implement of a very novel character. Perhaps, the most original stand is that of A. B. Childs, and in particular the exhibit No. 5,782, a chaff-cutting machine, invented by Messrs. Gittus and Leggett, of Mildenhall, Suffolk. The knives are moveable, and they are driven by an eccentric fixed to the fly-wheel, being arranged in such wise as to give a drawing cut just like the old hand-knife. One new thing—if we may so term it, for it is rather the application of a novelty, than a novelty itself—is the greatly-spread adaptation of Bruckshaw and Underhill's elevator to thrashers; an improvement effecting a great simplification of these still much-to-be-simplified machines. We gave a description of this grain-elevator in our number for the 12th of June (p. 424). Its general principle may be said to simply consist in the grain being brought into immediate contact with the blades of a common fan; the grain is thus cleaned and elevated by the conjoint action of the percussion, centrifugal force, and the blast, generated by the revolution of the blades. The bringing forward of this valuable arrangement, has directly and indirectly effected quite a revolution in thrashing machines; and we have probably not yet seen the last and most forward shape in which this improvement may be carried out. It is, perhaps, not generally known that this adaptation of the common fan has been proposed nearly a century and a half ago, and has been in extensive use for many years by our ingenious neighbours across the channel. The principle of Bruckshaw's elevator, will be found described in a work in the British Museum of so old a date as 1716. In the third volume of that well-known and famous work, the "Machines Approuvées par l'Academie des Sciences," p. 101 to 103, will be found the following remarks, at the end of a description of an ordinary fanning machine:—"Le Baron de Knopperf indique, tout d'abord l'usage qu'on pourrait faire de ce même ventilateur comme d'un veritable tarure, propre à battre le blé tombant d'une tremie sur ses planchettes, d'on il serait *lance et chape* à des distances diverses correspondant à autant de cases separées," &c. This idea was fully carried out more than twenty years ago by Zerôme Brothers, of Amiens (Somme), in France, who, we believe, actually exhibited "a machine for winnowing buckwheat," embodying this principle, in the Great Exhibition of 1851, as appears by the Official Catalogue, vol. III, p. 1,204. These French machine-makers have taken several patents for winnowers embodying the principle of elevating grains by the direct use of a fan. *Vide* "Description des Machines et Procédés pour lesquels des Brevets d'Invention ont été pris, &c. Publiée par les orders de M. le Ministre de l'Agriculture du Commerce, et des Œuvrages Publics." These machines are fully illustrated and described in vol. viii., p. 135, plate 17; vol. xxiii., p. 25, plate 7; vol xxix. p. 106 to 109, plate 21, &c. A description and illustration of Zerôme's winnower will also be found in the first volume of "Génie Industriel" of Armangand, a work which was by-the-bye, exhibited in the Great Exhibition of 1851. There is little doubt that Mr. Bruckshaw invented his elevator independently of his French forerunner; but what becomes of his patent right under such circumstances? These works have been before the English public, in the Patent-office library and in the British Museum long anterior to the date—1858 we believe—of his patent.

MAGNETO-ELECTRIC MACHINES.

One of the principal obstacles encountered in the practical application of electricity as a motive power, is found in the small amplitude of the elementary movements of electro-magnets, since their powers of attraction do not commence till they are almost in contact—the limit of distance varying from 1 to 2 millimetres at most.

Thus, all inventors who have proposed their use as a means of producing motive power, have sought to overcome the difficulty by causing the attraction to exert its powers at an angle, or by following the surface of a cone so as to augment the amplitude of the movements, with, however, a proportionate decrease of power. We now propose the adoption of a new combination to be called *contracteur electrique*, which shall imitate the play of the muscles in the organized body, and which will permit the transformation of the trifling direct motion of a series of electro-magnets, into a movement, ten, twenty, or a hundred times as great.

If we take discs of soft iron, and convert them into very deeply-grooved pulleys, in order that they may receive some thousands of turns of insulated copper wire, we can thus transform them into magnets by the passage of an electric current through the wire. If we superimpose a number of these discs, separated by small rings of india rubber, one millimetre thick, on the passage of a current, all the discs will approach each other, compressing the india rubber; and thus the pile of discs, if composed of 200 elements, for example, will shorten or contract on itself one decimetre, although each disc moves through but one half millimetre.

This is the first idea of contractors or electric muscles.

It is easy to understand that by fitting one end of such a pile to the connecting rod and crank of a fly-wheel, and the other extremity to a fixed support; we can obtain as great a number of revolutions as we desire, with a force depending on the power of the pile. By combining this idea with that of tubular electrical piles producing electricity in quantity, shall we not find the solution of the problem of applying electricity to the economical production of motive power?—*Portefeuille Economique de Machines.*

BOILER RIVETING IN THE UNITED STATES.

(From "Practical Notes on Steam," by W. H. King, U.S.N.)

In the United States there are three mechanical modes of uniting plates together; namely, *machine-riveting*, and *hot* and *cold hand-riveting*. On the seaboard, all kinds of boilers are riveted by the two first-named methods, in both of which the rivets are put in hot. West of the Alleghanies, all riveting is done by hand, and at Pittsburgh, Louisville, and other places, the rivets are driven cold in all places accessible for the purpose.

For the cold process, a superiority is clamed consequent upon the holes being well filled with the body of the rivets; that is, there can be no contraction—hence reduction in the strength and in the rivets' diameters after the workmen cease hammering on the heads. The reverse must be the case when driven hot; for, in cooling, the diameters are reduced by contraction. Moreover, none but the best quality of iron can be used in rivets driven cold; because, if the iron be inferior, it is sure to crack or split through the head, each one being tested by the heading.

For hot riveting, it is claimed that, in cooling, the rivets contract in length, drawing the sheets more closely together, thereby creating adhesion sufficient to add to the strength of the joint.

Mr. Clarke, resident engineer of the Britannia-bridge, made some experiments to determine the value of this. Three plates were riveted together by a machine, maintaining a temperature of 900 deg. in the rivets; each outside plate had a circular hole in which the rivets fitted exactly; but in the centre one the hole was oval, or 2¼ in. long for a ⅞ rivet, and the rivet was not allowed to touch either end of this hole. A strain was then put on the centre plate till it began to slide, which it did abruptly. Several trials were made, and the least result was an adhesion equal to 4½ tons with ⅞ rivets. Mr. Clarke infers from this experiment that, by judicious riveting, the adhesion may in many cases be nearly sufficient to counterbalance the weakening of the plates from punching the holes. In this particular we regard his opinion as an error; for if he had continued the strain on the plate until it parted, or the rivets broke, he would doubtless have found that the total pressure, or breaking strain, would have been 56 per cent. if single-riveted, and 75 per cent. if double-riveted, of the sheet, as fully tested by other experiments. Theoretically, there is a gain from adhesion in hot-riveted joints, but practically this seems to be lost by the contraction of the rivets' diameter, thus making the total or breaking pressure the same.

In western river boilers, where the pressure of steam used is higher than in any part of the world, no difficulty has ever been experienced from the cold-riveted joints not being closely united and perfected tight; and as regards strength compared with the hot-riveted, superiority is claimed by those having cold-riveted boilers in charge.

In either mode of hand-riveting the rivets can be seriously injured by too much hammering, and in any case by overheating. Due regard should be had to the temperature, and the blows of the hammer should be hard and quick, and not continued longer than necessary to form the head. Machine riveting has the advantage of forming the head at a single blow, and the rapidity with which the work can be performed must always give it preference over all other methods where it can be employed.

It is to be regretted that no extended set of experiments have ever been made in this country to determine the relative strengths of the different modes of riveting and uniting the sheets of steam boilers and other iron structures; also to test the relative value of the materials used in this country at the present day; for it must be evident that although the results of European experimenters on iron and steel are of value to us, yet they cannot be regarded as entirely applicable to American constructions, because our iron ores, the temperature of blast of smelting furnaces, and manner of working the metal through the different processes, and the fuel used, all differ in a large degree from those abroad.

SHOEMAKING BY MACHINERY.

THE employment of machinery in the manufacture of boots and shoes is of but recent date, but it has effected a wonderful revolution in this important industrial art. On this subject the Lynn (Mass.) *Reporter* says:—

Comparatively few people are aware of the quiet but steady revolution that is going on in the buisness of shoemaking, and particular as that buisness is conducted in Lynn. Previous to the introduction of the original sewing machines, which are now universally used for the binding and stitching of the uppers, but little or no improvement or even change had been made in the manufacture of shoes. The awl, the bristle, and thread, the lapstone and hammer, with plenty of "elbow-grease," were, as they had been for years, the main appliance of the shoemakers, and little was known or thought of labour-saving machinery. After a time women's nimble fingers were found inadequate to the demand, and sewing machines soon transformed the old-fashioned "shoe-binders" into a new and more expansive class of "machine girls" whose capacity for labour was only limited by the capabilities of the machines over which they presided. Iron and steel came to the aid of wearied fingers and weakened eyes. This was the beginning of the new era, which is destined to produce results big with lasting benefit to our flourishing city.

It is scarcely ten years since the first introduction of machinery of any kind into the manufacture of shoes in this city. Everything was done by hand, even to the cutting out of the soles, which was a slow process and required the expenditure of a large amount of physical force. The introduction of sole-cutting and stripping machines, although sparingly, was the first indication that a change was to take place in the buisness of shoemaking; but no one, even ten years ago, would dare to have prophesied that the change was to be so immediate and so great. The rapid progress that has been made during that time, and especially within the last year or two, in the introduction of machinery in shoemaking has been beyond all previous calculation. It may almost be said that hand-work has already become the exception, and machinery the rule. The little shoemaker's shop and the shoemaker's bench are passing rapidly away, soon to be known among us no more; and the immense factory, with its labouring steam-engine and its busy hum of whirling wheels, is rising up in their place, to change the whole face of things in this ancient and honoured metropolis of the "workers in the gentle craft of leather."

The problem as to how best to bring in and concentrate the vast army of men and women employed in the shoe manufacture of Lynn is one that has attracted the attention of many thinking minds among our business men, but it has never been satisfactorily solved until now. Machinery, and particularly the sewing machine, has done in a few short months what years of theorizing and speculation could not do. It has demonstrated that the factory system can be successfully and profitably introduced into the shoe business; in fact, that, with the rapid strides which the business has made within a few years, it is the only system that can be made available for its successful application in future. Of course, the new system is yet in its infancy—the business is yet in a transition state; but the wheels of revolution are moving rapidly, and they never move backward. Operatives are pouring in as fast as room can be made for them; buildings for "shoe factories" are going up in every direction; the hum of machinery is heard on every hand; old things are passing away, and all things are becoming new. Could the disembodied spirits of some of our old-time inhabitants visit the scenes of earth once more, how great would be their astonishment at the change which has taken and is taking place in this once quiet town which claimed them as citizens!

THE ASTRONOMER ROYAL'S REPORT.

THE Astronomer Royal has sent us a copy of his report to the Board of Visitors, dated June 6th, 1863. Among the results of the past year's labour at the Observatory we read:—

"The meridional observations of Mars, in the autumn of 1862, have been compared with those made at the Observatory of Williamstown near Melbourne, Australia, and they give for mean solar parallax, the value 8·932 sec., exceeding the received value by about 1-24th part."

"The mean magnetic declination for 1862 is about 22 deg. 52 min.; the diminution in the year appears to be 13 min. The mean dip for 1862 is about 68 deg. 11 min.; at the present time it appears to be 68 deg. 4 min."

Considerable labour has been given to a numerical discussion of the Magnetic Storms, from 1841 to 1857. The reductions are not quite finished; but they have suggested to Professor Airy the idea, apparently confirmed by a separate deduction from the magnetic phenomena attending the splendid aurora seen December 14th, 1862, that, "the action of the earth-currents upon the magnet is in the same direction in which the earth-current flows, and not transverse to the current direction as is usual with galvanic currents." This result is certainly very remarkable. The Astronomer Royal adds:—"If this should be confirmed, then, viewing the rarity of disturbances in the vertical direction as produced by magnetic storms, and their great violence when they do occur in the vertical direction, I shall have no hesitation in suggesting, as a general theory of magnetic storms, that the idea of attraction is to be abandoned, and that they are to be referred to currents of a magnetic ether whose movements are closely analagous to that of air, the vertical movement of which occurs but in few places, but in these places is excessively violent. Much, however, must be done before such a theory can be established."

As regards chronometers and the communication of time, this is what the report states:—

"The number of chronometers on hand at this time is 132; of these, 82 are compared with a standard clock every day, and the others are compared on one day in every week. The standard clock is one of a series of galvanic clocks whose movements are necessarily synchronous with that of the motor clock; which is accurately adjusted to mean solar time by means of a galvanic action upon its pendulum, that can be used for any arbitrary length of time to accelerate or retard the clock by slow degrees during that time. Every chronometer, whatever be the reason of its lodgment at the Royal Observatory, is tried during some part of its stay in the heated chronometer oven.

"When it is necessary to decide on the merits of chronometers, either as affecting their price for purchase, or as deciding their place in the published order of merit, the decision is made by me. The repairs of chronometers the property of the Government are entirely managed by me.

"The drop of the time-signal-ball at Deal, by a galvanic current from this Observatory, which is automatically given by the corrected motor clock, is perfectly efficient, no failures occurring except from the defects of adjustment of the clock at the London-bridge station which changes the connections of wires. Time-signals are sent daily along the principal lines of railways, the most distant points (I believe) being Glasgow and Cardiff. I have also heard that the companies, through whose offices the wires pass, have begun to distribute branch signals to private factories.

"The clocks of the General Post Office are connected as formerly with the Observatory, each of four clocks being adjusted by current from our motor clock once every day, and reporting itself to us twice every day. The clock of Westminster Palace has also been brought into connection, the attendant receiving a signal from us once every hour, and the clock reporting its state to us twice every day. As far as I have yet observed, the rate of this clock may be considered certain to much less than one second per week."

Legal Intelligence.

SOUTHWOOD V. FAIRBAIRN.

THE question involved in this trial, which took place at Oxford, before Mr. Baron Martin, is one of some interest to engineers. Mr. Serjeant Pigott and Mr. Gray were for the plaintiff; Mr. Davis for the defendant.

The plaintiff is an engineer now living at Birmingham, but has spent many years in the Australian diggings. On his return home he took out a patent for crushing quartz and all descriptions of ore and stones, not only for extracting gold, but for the purpose of metalling roads. In November he entered into a contract with the defendant, an engineer in Southwark, to make and erect on the defendant's premises, and work with 10 or 12-horse power, and make ready for experiments, one of those machines within two months for £95, £40 to be paid during or on the completion of the machine. A dispute subsequently arose, and the defendant refused to complete the contract, although the plaintiff had paid him £20 on account. This refusal the defendant did not now attempt to justify, and paid £40 into court; therefore, the only question was the amount of damages to which the plaintiff was entitled. The plaintiff claimed as damages his inability to exhibit the machine or to execute various contingent orders which would each have realized a profit, or to carry out arrangements he had made for going out to Australia to push the patent under the auspices of a company. The defendant contended that such damages were rather conjectural than substantial.

The learned Baron said the difficulty was to lay any fixed rule as to what were direct and proximate damages, and that it was one of those matters which lawyers, when puzzled, put upon the jury, but that annoyance or vexation arising from unpunctuality was not a subject for damage.

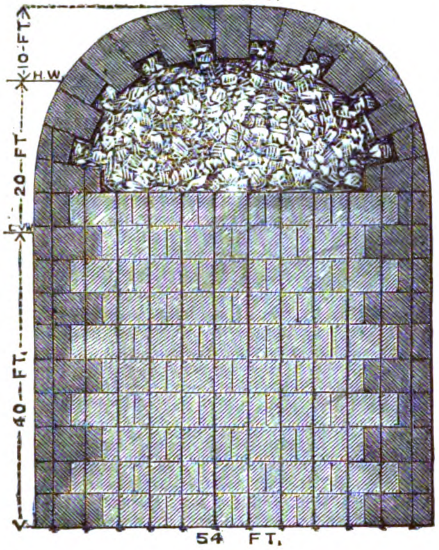
The jury found a verdict for £30 more than the sum paid into court.

IMPROVEMENTS IN THE CONSTRUCTION OF HARBOURS, BREAKWATERS, PIERS, JETTIES, SEA AND RIVER WALLS, &c.

By Alexander Doull, C.E.

Fig. 1 is the section of a breakwater with vertical walls constructed in 10 fathoms water, 40 ft. below low water, and 20 ft. between high and low water, and 10 ft. above high water, making 70 ft. as the whole height of the structure.

FIG. I.



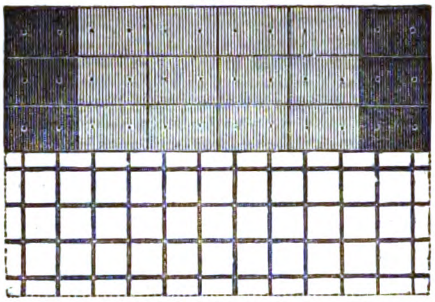
The section is 54 ft. wide at the base, and is carried up perpendicularly to about 10 ft. above low water line, and is then finished by a flat curve. It is considered that the curved form given to the top of the work will secure the stones more firmly in their positions, and will allow the top of the wave to pass over the wall and fall into the harbour without propagating a wave or causing an inconvenient disturbance of the water in the harbour, and also with the least possible injury to the wall. In this section the work is composed of stone blocks, averaging 9 ft. long, 4½ ft. broad, and 4½ ft. thick, weighing about 11 tons each. These stone blocks are placed headers and stretchers in the outside of the work, the inside being filled up by concrete blocks of the same dimensions. The dimensions of the blocks, both of stone and concrete, would, however, be occasionally varied in length and thickness, in order the more effectually to break bond horizontally and vertically. The concrete blocks in the interior of the work would be continued up to the low water line, after which the centre of the work would be composed of concrete in mass, and the outside and top of stone block, which may be cramped together in any convenient manner.

The blocks of stone and concrete are placed in position up to the low water line by guide rods of malleable iron, about 3 in. in diameter, two rods passing through each block. The holes in the blocks of stone would probably be more economically and accurately bored by machinery; the holes in the concrete blocks would be moulded in them at the time of their formation, and would consequently cause no additional expense.

During the process of construction, the rods would be carried up to the staging, and the upper ends of them secured in such a manner that any two of them could be disengaged and inserted into the hole of the block previously to its being lowered into its position from the staging.

In order to place the rods at the proper distance from each other, and to retain them in that position, agreeing accurately with the holes in the several blocks, the grating, fig. 2, is made use of. It is composed of flat bars of malleable iron, about 6 in. broad and half an inch thick, riveted or welded together, and holes bored at the intersections of the bars accurately corresponding to the holes in the block. This grating would be formed in convenient lengths.

FIG. 2.



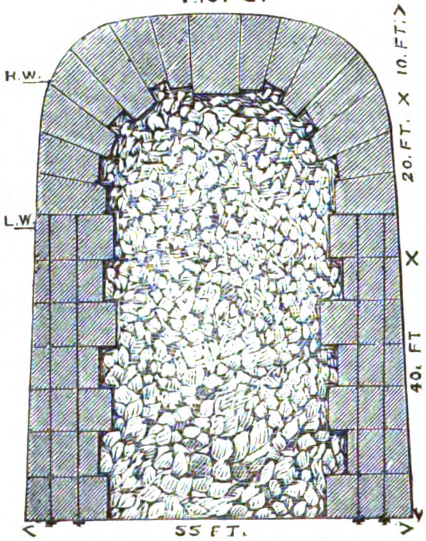
The rods having been screwed together and the upper ends attached to the platform as near their proper positions as possible, and their lower ends resting on the ground, the grating is passed over the ends of the rods and allowed to drop down along the rods to the ground, and to rest upon the heads of the rods, and thus form an efficient gauge to preserve the rods in their proper relative positions ready for the deposit of the stone and concrete blocks. In connecting one length of the grating with a previous one in the onward progress of the work, the advanced row of rods must be left clear of blocks, in order that the set of holes in the next portion of grating shall pass over the rods in the advanced holes of the previous grating. It will thus be observed that two sets of holes will pass over one set of rods at the junction of every successive portion of the grating.

This mode of construction would be well suited for such works as those which are at present being carried on in connection with the proposed Harbour of Refuge at Dover, and which is said to cost about £1,100 or £1,200 per yard forward. The slow progress of the works, consequent upon diving-bell operations, is so great, and the expense of construction so excessive, that no reasonable hope can be entertained of ever obtaining a Harbour of Refuge at Dover by the means at present in operation.

The only alteration necessary to be made from the above in the construction of *circular pierheads*, would be to form the iron grating used for the proper adjustment of the guide rods in a circular or any other required form, and to prepare the holes in the stone or concrete blocks to correspond to the position of the rods. This, it is presumed, would be an expeditious and cheap mode of constructing pier-heads in connection with breakwaters where the whole of the materials had been thrown into the sea from tramways, but where the pier-heads are, as at present, constructed by the aid of the diving-bell.

The following (fig. 3) is a still cheaper mode of constructing a harbour of refuge than that already described:—

FIG. 3.



The outside courses are constructed of blocks of concrete, faced on the ends and sides, which are exposed to the wash of the water with hard blue bricks, manufactured expressly in such a manner as to unite more effectually with the concrete. These brick facings would be carefully built in cement in the end or side of the mould in which the concrete block is formed. The brick-work would be competed, and the concrete poured in afterwards; or the two materials could be applied simultaneously. Holes for the guide rods would be preserved in the blocks when they are being moulded.

Blocks of a large size may also be used, probably from 40 to 50 tons weight; and by substituting cast for malleable iron in guide rods, it being more durable than malleable iron in sea water, considerable stability would be derived from the guide rods, as they could be screwed into proper guage by the grating already described.

The centre of a construction of this description may be composed of rubble stone, brought up in layers corresponding with the outside block courses. On the top of each layer of stone, liquid concrete would be put down in boxes or leather tubes, sufficient to fill up the interstices of the stone rubble.

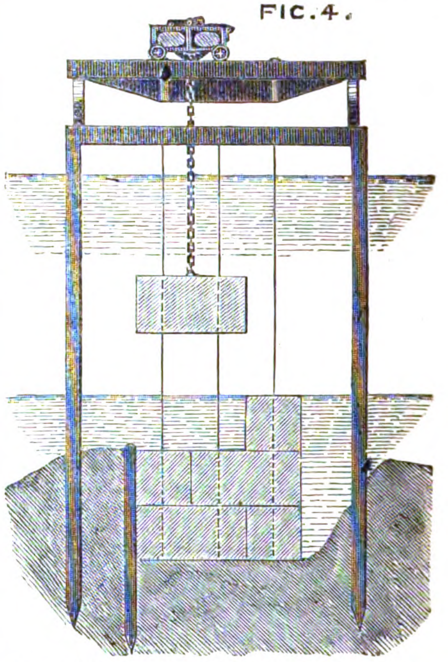
In some situations the chalk could be employed for the purpose of filling. The only essential condition in this case would be, that no water should be allowed to pass in through the exterior block casing to wash away the chalk. The economy would also be very great where hard block chalk in abundance can be found upon the spot.

The expense of a structure of this description would probably be about £150 per yard forward, or about two miles of wall for little more than half a million of money.

In constructing a breakwater (such, for example, as in the bay of Wick), where the stone to be used is of the nature of slate, or large slabs comparatively thin: in this case it is essential that the stone should be placed vertically in the outside of the work; for, if large flat stones are thrown into the sea from a staging, they would spread out to a very inconvenient extent.

For the purpose of placing the stones composing the outsides of the work in a vertical position, or nearly so, a frame (somewhat similar to those used in hoisting materials to buildings) would be used, extending from the staging to the

FIG. 4.



bottom of the sea, and capable of being raised or lowered according to the irregularities of the bottom. To this frame a slide would be attached, upon which the stone would be placed, and, when lowered into its position, the slide would be also

arranged that a portion of it would be acted upon from the platform so as to cast the stone forward into its place. The weight of the stone about to be placed would press out the lower end of the vertical frame sufficiently far from the finished work to admit the deposit of stones successively sent down in the progress of the work. A diver could be occasionally sent down to examine the progress of the work.

Fig. 4 is a cross section of a river wall, about 12 ft. or 15 ft. below low water, and in about 10 ft. of excavated mud or gravel. Staging is erected over the length of the portion of wall in progress, and the excavation is effected to the necessary depth by a vertical dredger, attached to a traveller in such a manner as to be readily placed over every portion of space to be operated upon. This dredger or excavator would be lowered as the work progressed, and by this means the bottom of the excavated portion would be formed perfectly level, ready to receive the concrete blocks. The concrete blocks would be formed of any convenient size, and each block would have two holes in it, for the purpose of being placed in position, as above described with reference to breakwaters.

Cast-iron sheet piling would be driven on the river side to protect the concrete blocks from the action of the current, and also to guard against injury to the foundation by the scouring out of the bed of the river when its breadth has been contracted.

This sheet piling on the river side, and temporary sheet piling on the land side, would be necessary to preserve the proper form of the excavation until the concrete blocks have been deposited.

This mode of putting in the foundation of river walls, it is presumed, is peculiarly applicable to the embankment of the north and south sides of the Thames, about to be undertaken by the Board of Works—more efficient and more economical than by sinking cylinders by divers.

TRIAL TRIP OF THE TWIN-SCREW STEAMER "DIANA."

THE trial trip of this vessel took place on the 30th of June last, and the results have been pronounced very successful. The following are the most important particulars:—

	h. m. s.		m. s.
No. 1. Full speed ahead	2 36 20		
Stopped	0 37 34	...diff.	1 14
114 revolutions way astern	0 39 10	... „	1 36
„ „ full speed	0 39 40	... „	0 30
Evolutions completed in ...	0 3 20		

No. 2. Full speed ahead,

	h. m. s.	m. s.	
helm hard a starboard	2 44 30		
120 revolutions ...	0 48 40	4 20	... 1st circle.
	0 58 18	4 18	... 2d „
	0 57 2	3 44	... 3d „

mean of three = 4 7·33

Diameter of circle described 3½ times length of vessel.

No. 3. One engine full speed ahead, helm hard a starboard—

	m. s.	h. m. s.	
half circle...	1 24 }	3 9 20	= 3 50...1st circle.
completed...	1 26 }	0 13 10	
half circle...	2 0		= 4 16...2d „
completed...	2 16	0 17 26	

The way being deadened and wind on the bow caused slight retardation.

No. 4. Engines working in opposition, starboard ahead, port astern—

h. m. s.	m. s.		m. s.
3 20 12			
0 23 48	3 36		
0 29 7	5 19	...... mean	4 27 5

To test the power of turning to avoid danger or pick up a man. Full speed ahead; helm suddenly put a starboard, port engine reversed—

	m. s.
half turn..................	1 25

The manœuvre of steering by the screws in going stern foremost, was then put under severe trial and performed admirably, but the greater depth of the keel and after body demanded very accurate seamanship. We trust soon to learn that Government will adopt more decisive measures for the introduction of this important aid to manœuvring ships-of-war.

NEW RAILWAY SYSTEM.

AN inquiry is open at the present moment in the departments of the Seine and Seine-et-Oise relative to a proposed railway which is to be laid down in a direct line, traversing all the inequalities of the surface of the country, from Paris to Marly-le-Roi. The concession for the proposed line has been made to M. le Baron Séquier, represented by M. Duméril, C.E., and is the result of demonstrations made at the Palace of the Tuileries of the advantages of a system laid before the Academy of Sciences on the 18th of December, 1843, by M. le Baron Séquier. The principle of this system is, shortly, the same as that which we have described, illustrated, and discussed in a memoir on railway in general, and on Jouffroy's system in particular. M. Séquier thus explains an invention which has remained for twenty years as a little model:—"We supply the cause of movement to locomotives by the pressure by springs of their wheels against rails and not in the simple adherence of the wheels to the rails by the weight alone of the machine.

"An ordinary railway, with simply a third rail of wood or iron laid down between the other two; locomotives nearly the same as those we have at present, only their driving wheels changing their places, and our problem is solved. Let us explain:—We propose that the two driving wheels, placed horizontally and acted on by very powerful springs, shall grasp the central rail—firmly fixed to the sleepers—between them, as a train of rolls does a bar of iron. The adhesion of the wheels then due to the pressure of the springs secures the fulcrum necessary for the propulsion of the engine and train.

"The power of the springs, then, which force the wheels horizontally against the rails, becomes the measure of the capabilities of the machine, instead of its weight. All attempts at producing a light locomotive have hitherto failed, because weight is necessary to adhesion. Here we see this difficulty at once overcome.

"A simple enlargement of the central rail, acted on, on inclines by smaller wheels on the same axle, suffice to augment the power of the locomotive. Thus, in a moment speed can be converted into tractive power or the reverse."

We earnestly hope that the labours of MM. Séquier and Duméril may be crowned with success.—*Les Mondes.*

ROYAL SCOTTISH SOCIETY OF ARTS.

ON Monday night, a meeting of this Society was held in their hall, 117, George-street, Edinburgh—Dr. Stevenson Macadam, President of the Society, in the chair.

The secretary (Mr. Beatson Bell) read the following reports by committees appointed to consider various communications made to the Society during the past session, which were approved of:—

The committee on Mr. T. Whimster's improvement in the working of hydraulic mains, reported that they were of opinion that the thanks of the Society were due to Mr. Whimster for bringing the subject of his paper before the Society, as, although the plan had been previously adopted, it is not generally known, and may be advantageously adopted in other gasworks.

The committee on Mr. Whimster's description of a self-regulating valve or compensator for gaswork exhausters, reported that the invention of Mr. Whimster showed a considerable amount of ingenuity, and would answer the purpose for which it was intended, but that it wanted the simplicity of several plans now in use for the same purpose, which were found to work without creating any inconvenience.

The committee on Mr. J. Laird's horizontal windmill, reported that the invention was not new, but that the same object was attained several years ago by Mr. George Buchanan.

The committee on Mr. Henry Kerr's new gravity escapements, reported that in all his inventions Mr. Kerr had displayed very great ingenuity; but that in them all there was a complication in the working parts which would render their construction very difficult, and might give rise to many sources of error when brought into action. The committee were therefore of opinion that though Mr. Kerr may have obviated some of the defects acknowledged in all gravity escapements hitherto invented, it was doubtful if his inventions, if carried out into practice, would be found to be real improvements.

The committee on Mr. Sang's communication on the sefinet equation for determining the form of a ship's hull, reported that Mr. Sang's communications on ship-building were worthy of the highest commendation.

The committee on Mr. William Paterson's improved signal, and method of working single lines of railway without risk of accident, reported that they were of opinion that the way of working "by a train staff" was equally safe with that proposed by Mr. Paterson, the handle required for opening the main signal being practically a train staff.

The committee on Mr. Robert Gray's apparatus for impregnating gases with the vapour of volatile hydro-carbon fluids, reported that they were of opinion that Mr. Gray's apparatus was by no means new, as similar arrangements for promoting the absorption of a liquid by a gas, and the converse, had been in use prior even to the date of Mr. John Reid's specification of patent for apparatus for saturating gas with water vapour. The committee were of opinion that Mr. Gray's apparatus was not more effectual for the purpose of bringing the gas into contact with the liquid, than Mr. Reid's arrangement.

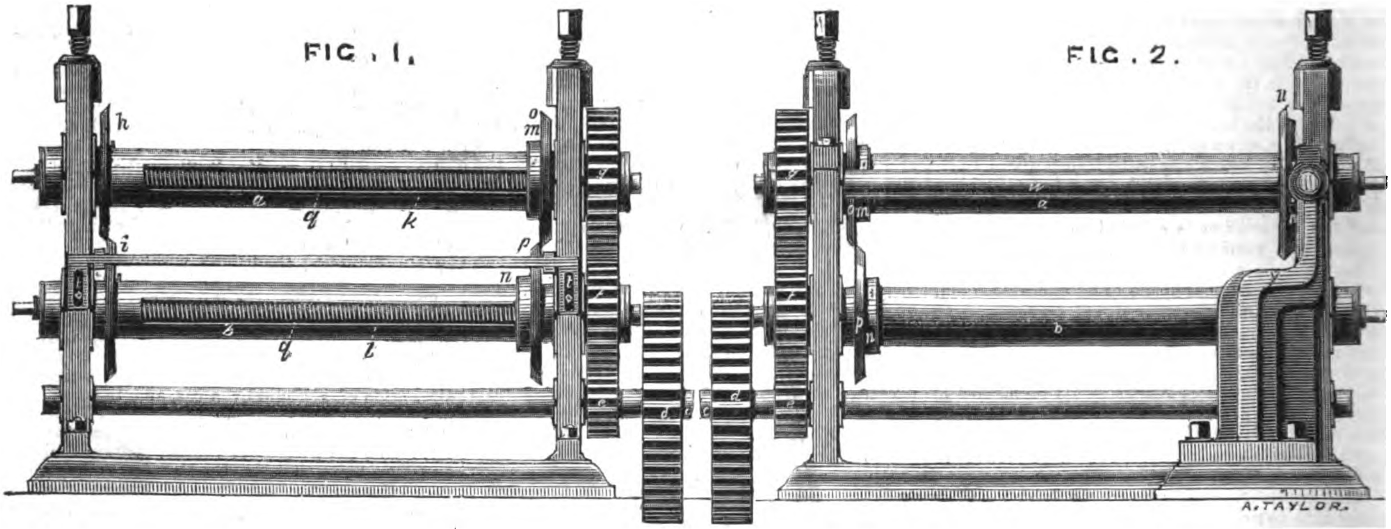
The committee on Mr. Joseph Polson's machine for blacking boots and shoes, reported that the machine was an improvement over the common method with hand brushes, and might be found useful where there was constantly a large number of shoes to be cleaned. At the same time, the committee did not think that the reciprocating brushes, which appeared to form the principal novelty in the arrangement, were so good as the rotary ones, as used by Mr. Polson for the first part of the operation, but which were used and found by other makers to be all that could be desired for the whole process.

The committee on the Rev. James W. Miller's communication "on the Effective Power transmitted from the piston-rod to the crank of the steam-engine, &c.," reported that they regretted they could not recommend Mr. Miller's communication to the favourable notice of the society.

TRIAL OF ENGINES FOR THE MANCHESTER FIRE BRIGADE.

THE re-organization of the Manchester Fire Brigade has led the Watch Committee to decide upon replacing several of their old engines with new ones. With a view to ascertain the merits of two engines that had been specially recommendad to them—one constructed by Messrs. Shand and Mason, of London, and the other by Mr. W. Rose, of Manchester—they were tried a few days ago in the police-yard. The points to which the Committee directed their attention were the weight of the engine, the quantity of water projected at certain heights and distances, general workmanship, and price. The testing apparatus consisted of a hood or target made of canvas, and placed so that it should slide from the top to the bottom of a scaffold 40 ft. high. In consequence of the spray from a jet being of little service when enlarged or radiated beyond 6 ft.—owing to evaporation—the target was only 6 ft. in diameter. The water thrown into it was conducted by a "shoot" into a measure tub, so that the quantity projected might be accurately ascertained. The experiments were conducted by Mr. Superintendent Tozer, in the presence of Captain Palin, the chief constable, and several members of the Watch Committee. Each engine was tested in ten different ways, and the result showed that in 14 minutes and 26 seconds Messrs. Shand and Mason's engine threw 2,482 gallons with 760 strokes, to project 1,500 gallons into the target, the loss being at the rate of about 35 gallons in every 100. In 12 minutes and 53 seconds Mr. Rose's engine threw 2,374 gallons with 632 strokes, to project 1,500 gallons into the hood, the loss being at the rate of about 34 gallons in every 100. The volume of water that was lost was probably greater than would have been the case had the weather been more favourable. With regard to other conditions than those of quantity and force of water projected—such as price, &c.—Mr. Tozer reports more favourably of Mr. Rose's engine than that of his competitors. The result of the trial and Mr. Tozer's report are at present under the consideration of the Watch Committee.—*Manchester Guardian.*

BECK'S METAL-CUTTING MACHINE.



BECKS' METAL-CUTTING MACHINE.

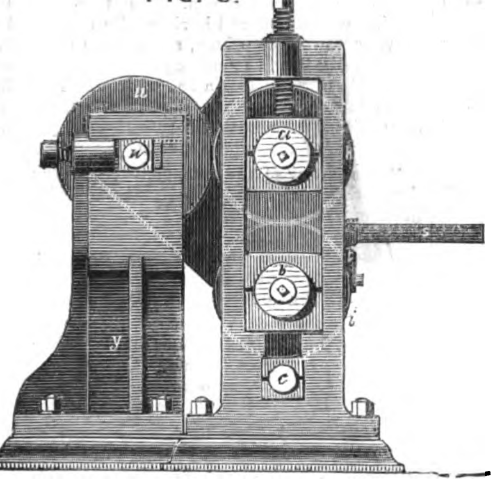
A PATENT has just been obtained by Mr. A. T. Becks, of Birmingham, for an invention for improvements in machinery for cutting or shearing the sides and ends of sheets or plates of metal.

The invention consists in arranging and working a series of rotating cutters in the manner hereinafter explained. Two parallel horizontal shafts situated the one over the other are driven by steam or other power by means of a pinion on a driving shaft. The pinion engages with a toothed wheel on the lower shaft, the toothed wheel engaging with a similar toothed wheel on the upper shaft. Each of the shafts carries, near the end opposite to that on which the toothed wheel is fixed, a circular or rotating cutter. These cutters are fixed on the shafts, and their cutting edges meet and cut one side of the plate or sheet of metal operated upon. The shafts are hollow, and in the axis of each a screw is situated. A screw-nut or box works on the screw in the interior of each hollow shaft. By turning the screws by a winch or otherwise the screw-nuts may be made to travel in one or other direction on the screws. A second circular or rotating cutter capable of a sliding motion is situated on each shaft, and is connected with the screw-nut or box in the shaft through a slot running nearly from end to end of the shaft. By turning the screws the moveable cutters may be made to approach to, or recede from, the cutters fixed on the shafts, so as to accommodate the distance between the cutters to the width of the plate or sheet to be cut or sheared. By passing the plate or sheet or sheets of metal through the machine in a horizontal direction, both their edges or sides are simultaneously cut or sheared parallel. The ends of the plates are cut by means of a fifth cutter, forming a pair with the fixed cutter on the upper shaft. This fifth cutter is fixed on a horizontal shaft situated parallel to, and in the same horizontal plane as, the upper hollow shaft, and is geared to the upper hollow shaft by a toothed wheel taking into a toothed wheel on the hollow shaft. The ends of the plate or sheet are cut or sheared one end at a time by passing them in a vertical direction between the last-described pair of cutters. The cutting or shearing may be affected without the fifth cutter, by passing the plate in a horizontal direction between the fixed pair of rotating cutters described, the plate being supporting on a moveable table.

Fig. 1 represents a front elevation; Fig. 2, a back elevation; and Fig., 3 an end elevation of the machine.

a, *b*, are parallel horizontal shafts situated one over the other, and driven from the main shaft *c*. Motion is communicated to the shaft *c* by means of the toothed wheel *d*, and the motion of the shaft *c* is transmitted through the pinion wheel *e* and toothed wheel *f* to the shaft *b*. A toothed

FIG. 3.



wheel *g* on the shaft *a* gears with the toothed wheel *f* on the shaft *b*, and communicates motion to the upper shaft *a*. Each of the shafts *a*, *b*, carries a fixed circular cutter marked *h* and *i* respectively, the cutting edges of the said cutters working in contact or nearly in contact. On the opposite ends of the shafts *a*, *b*, are two other rotating cutters *o*, *p*, capable of being made to slide along the said shafts *a*, *b*, and thereby to approach to or recede from the fixed rotating cutters *h*, *i*. The shafts *a*, *b*, are hollow, and are furnished respectively with screws *k*, *l*, situated in their axes. Each of the screws *k*, *l*, passes through a screw-nut or screw-box carried by the collars *m*, *n*, of the moveable cutters *o*, *p*, the said screw boxes passing through slots *q* in the hollow shafts *a*, *b*. By turning the screws *k*, *l*, by winches applied to the square ends, the moveable cutters *o*, *p*, may be brought to the required distance from the fixed cutters *h*, *i*, that is, to to the distance equal to the width to be given to the cut or sheared plate, sheet, or sheets. By passing the plates or sheets of metal to be cut or sheared through the machine in a horizontal direction, both their edges or sides are simultaneously cut or sheared parallel. The plates are supported in their passage through the machine on the table *s*, the table being capable of being raised or lowered by means of screws and slots at *t*.

When the machine is to be used for cutting or shearing the ends of the plates or sheets of metal, a fifth cutter *u* is added. This cutter is carried by the shaft *w*, supported on a standard *y*, and rotary motion is given to the shaft *w* by a toothed wheel *x* thereon gearing with the toothed wheel *g* on the upper hollow shaft *a*. The cutter *u* forms with the fixed cutter *h* a pair of cutters, by means of which the cutting or shearing of the ends of the plate is effected. The plates are held in a vertical plane, and are made to descend vertically between the cutters *h*, *u*. After one end of the plates have been cut or sheared, they are turned, so as to bring the other end under the operation of the cutters *h*, *u*.

INSTITUTION OF CIVIL ENGINEERS.

THE Council of the Institution of Civil Engineers have awarded the following premiums for Papers read at the meetings during the session 1862-63:—

1. A Telford medal, and a Telford premium, in books, to John Brunton, M. Inst. C.E., for his "Description of the Line and Works of the Scinde Railway."

2. A Telford medal, and a Telford premium, in books, to James Robert Mosse, M. Inst. C.E., for his Paper on "American Timber Bridges."

3. A Telford medal, and a Telford premium, in books, to Zerah Colburn, for his Paper on "American Iron Bridges."

4. A Telford medal, and a Telford premium, in books, to Harrison Hayter, M. Inst. C.E., for his Paper on "The Charing Cross Bridge."

5. A Telford premium, in books, to William Michael Peniston, M. Inst. C.E., for his Paper on "Public Works in Pernambuco, in the Empire of Brazil."

6. A Telford premium, in books, to William Henry Preece, Assoc. Inst. C.E., for his Paper "On Railway Telegraphs, and the Application of Electricity to the Signalling and Working of Trains."

7. A Telford premium, in books, to Alexander Woodlands Makinson, M. Inst. C.E., for his Paper "On some of the Internal Disturbing Forces of Locomotive Engines."

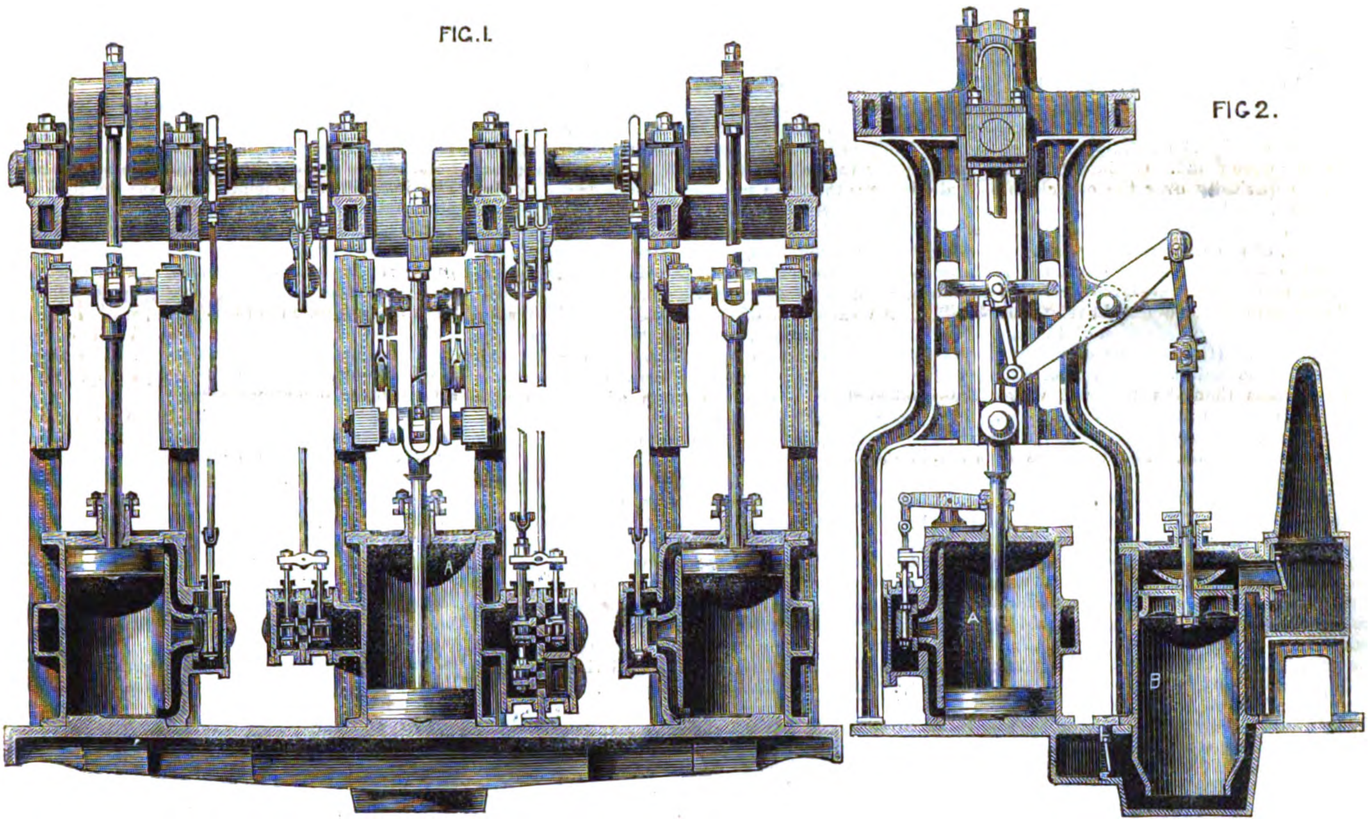
8. A Telford premium, in books, to Daniel Miller, for his Paper on "Structures in the Sea, without Cofferdams,—with a Description of the Works of the New Albert Harbour at Greenock."

9. A Telford premium, in books, to Robert Crawford, Assoc. Inst. C.E., for his Paper on "The Railway System of Germany."

10. A Telford premium, in books, to William Cudworth, M. Inst. C.E., for his Paper on "The Hownes Gill Viaduct, on the Stockton and Darlington Railway."

11. A Telford premium, in books, to James Grant Fraser, M. Inst. C.E., for his Paper "Description of the Lydgate and of the Buckhorn Weston Railway Tunnels."

HENDERSON'S IMPROVEMENTS IN STEAM-ENGINES.



12. A Watt medal, and the Manby premium, in books, to John Fernie, Assoc. Inst. C.E., for his Paper "On the Manufacture of Duplicate Machines and Engines."

HENDERSON'S IMPROVEMENTS IN STEAM-ENGINES.

THE above engravings illustrate an invention recently patented by Mr. G. Henderson of Mincing-lane.

The invention consists in a peculiar combination of parts, by which it is proposed that some of the steam generated may be used in two or more cylinders in succession without that back pressure on the piston in the first cylinder which has heretofore resulted when using steam expansively in two or more steam cylinders. The combination is such that each of the steam cylinders is capable of being put in communication with a condenser or with the outer atmosphere on one side of the piston when steam is being admitted into the cylinder on the other side of the piston. To accomplish this, the steam is expanded from the first steam cylinder A, into a vessel or accumulator B, from which the steam is supplied to another steam cylinder C, the communication between the first steam cylinder and the accumulator being closed by a suitable valve when steam from the accumulator is being supplied to the second steam cylinder. The working of the machinery is such that on opening the exhaust from the first steam cylinder, the steam expands into the accumulator of the second steam cylinder and then to the condenser, if only one additional cylinder be employed; but if more than one additional steam cylinder be used then, the exhaust having been opened to the first accumulator, it is cut off therefrom, and the exhaust steam is then allowed to expand into a second accumulator of the second additional steam cylinder before the exhaust of the first cylinder is allowed to pass to the condenser.

AMERICAN COLLIERY ENGINEERING.

A CORRESPONDENT of the *Scientific American* writes as follows:—On the Ashland estate, in the vicinity of the town of Ashland, are located two large collieries—one, worked by Bancroft, Lewis, and Co., employing between four and five hundred hands; and the other, worked by Mr. Moody, almost as many. These collieries are situated on opposite sides of the Mahanoy creek, and the slopes in each have been sunk to the depth of 600 ft. perpendicular. The mining engineer of the estate, seeing the great advantage to be derived from having the draining of both mines effected by one pump, proposed that an engine should be constructed of sufficient power to perform the required work. A direct-acting engine of 500-horse power was built by the firm of Pott and Vastine, of Pottsville, and erected at Bancroft's colliery, and having been found to work satisfactorily, the work of connecting the two collieries was commenced. This, as all engineers will understand, was a most difficult undertaking. The intervening distance between the two slopes consisted partly of precipitous mountain side; and the slopes, following the pitch of the vein to the depth of 600 ft., were very steep and unfavourable for the use of instruments. A small gangway, merely large enough to allow the workmen room, was started at 500 ft. below the water-level in the eastern colliery, and driven forward with the intention of meeting a similar gangway from the western colliery; but as the miners advanced, the influx of water became greater, and finally, owing to some accident to the pump, drove the men out and arose 300 ft. in the slope, completely drowning out the lower part of the mine. The western gangway was then driven to within 60 ft. of the flooded gangway, and preparations made for boring through the intervening mass of coal and slate. A strong battery of heavy timber was first erected to prevent the washing away of the coal by the immense pressure of the 300 ft. of water about to be tapped. The drill was then put into operation, and with such nicety and skill had the gangways been driven, and so exactly was the direction of the drill determined, that the water was struck at the first attempt. Only from an actual inspection of the collieries can an idea be formed of the delicacy of levelling and measurement required to execute succesfully such a work, where the smallest error in the direction of slope of the gangways would involve everything in inextricable confusion. Mr. H. H. Fisher, the engineer under whose direction the work was performed, has had for several years the entire control of the engineering department of the Ashland estate, upon which are stuated some of the largest collieries in Schuylkill county.

RESEARCHES ON RADIANT HEAT.*

IN his former researches on the radiation and absorption of heat by gaseous matter, the speaker com pared different gases and vapours at a common thickness with each other; one part of his present object was to compare different thicknesses of the same gaseous body with each other as to their action upon radiant heat. A few years ago he would be deemed a bold man who would attempt to measure the action of an inch, or indeed of many feet of a gas, on radiant heat; but the present experiments commence with plates of gas only 0·01 of inch in thickness, and extend to thicknesses of 49·4 inches. Thus, the greatest thickness is to the least nearly in the ratio of 1 to 5,000. The apparatus employed for the smaller thicknesses was a hollow cylinder, one end of which was closed by a plate of rock-salt. Into this fitted a second cylinder, with its end also closed by a plate of the salt. One cylinder is moved within the other like a piston, and by this means the two plates of salt could be brought into flat contact with each other, or

* Abstract of Paper read before the Royal Institution June 12, by JOHN TYNDAL, Esq., F.R.S.

could be separated to any required distance. the distance between the plates was measured by a *vernier*. The cylinder was placed horizontal, being suitably connected with a source of heat. This latter consisted of a plate of copper, against which a steady sheet of flame was caused to play.

The absorption of radiant heat by carbonic oxide, carbonic acid, nitrous oxide, and olefiant gas was determined with this apparatus, and such differences as might be anticipated from former researches were found. Olefiant gas maintained its great superiority over the other gases at all thicknesses. A layer of this gas, not more than 0·01 of an inch in thickness, intercepted about 1 per cent. of the total radiation; and the delicacy of the apparatus may be inferred from the fact that this absorption—great, relative to the thickness of the layer of gas, but small absolutely—corresponded to a deflection of 11 degs. of the galvanometer. (It would be certainly possible to measure the action of a layer of this gas of less thickness than the paper on which these words are printed.) A layer of olefiant gas, 2 in. in thickness, intercepts nearly 30 per cent. of the entire radiation. The influence of a diathermic envelope surrounding a planet may be strikingly illustrated by reference to this gas. A shell of olefiant gas 2 in. thick, surrounding the earth, would offer no appreciable hindrance to the solar rays in their earthward course; but it would intercept, and in great part return, 30 per cent. of the terrestial radiation: under such a canopy the surface of the earth would probably be raised to a stifling temperature. A layer of the gas, 3-10ths of an inch thick, intercepts 11·5 per cent. of the whole radiation. Such a layer if diffused through a stratum of air 10 ft. thick, would be far more attenuated than the aqueous vapour actually diffused through the air; still it would produce an absorption greater than that which the speaker had assigned to the atmospheric vapour within 10 ft. of the earth's surface. In the presence of such facts, the arguments which we might be disposed to base on the smallness of the quantity of atmospheric vapour are entirely devoid of weight.

In measuring the action of larger thicknesses of gas, the following method was pursued:—A brass cylinder, 49·4 in. in length, had its two ends stopped with plates of rock salt, and a suitable source of heat placed at one end; the rays from this source passed through the tube, and were received by a thermo-electric pile placed at its opposite end; this radiation was exactly neutralized by the heat emitted from a cube of boiling water and incident on the opposite face of the pile. The interception of any portion of the heat emanating from the source by a gas or vapour introduced into the tube destroyed the equilibrium previously existing, and the amount intercepted was declared by the galvanometer. The thickness traversed by the calorific rays was varied in the following way:—The tube was divided into two distinct compartments by the introduction of a third plate of rock salt. Let us agree to call the compartment most distant from the pile the first chamber, and that adjacent to the pile the second chamber. The experiments began with the first chamber short and the second chamber long, and ended with the first chamber long and the second chamber short. The alteration consisted solely in the shifting of the intermediate plate of salt, which lengthened the first chamber and diminished the second one by the same quantity; the sum of the length of both chambers being the constant quantity, 49·4 inches.

The absorption effected in the first chamber acting alone was first determined; then the absorption effected in the second chamber acting alone; and, finally, the absorption effected when both the chambers were occupied by the gas or vapour. This arrangement enabled the speaker to check his experiments, and also to examine the effect of the shifting which occurred in the first chamber on the absorption of the second one. The thermal coloration of the various gases was rendered strikingly manifest by these experiments; for the vast majority of the rays—for example, carbonic oxide and carbonic acid—are transparent. Placing a stratum of carbonic oxide, 8 inches in length, in front of a column of the same gas, 41·4 inches long, these 8 inches intercepted 6 per cent. of the whole radiation; placed behind a column, 41·4 inches long, the absorption of the same 8 inches was sensibly *nil*. So also with carbonic acid; 8 inches in front absorbed 6½ per cent., while placed behind the effect was almost zero. Similar remarks apply to the other gases, the reason manifestly being that when the 8-inch stratum is in front, it stops the main portion of the rays which give it its thermal colour, while, when it is placed behind, these same rays have been almost wholly withdrawn, and to the remaining 94 per cent., or thereabouts, of the radiation the gases are sensibly transparent.

An extension of this reasoning enables us at once to conclude, that the sum of the absorptions of the two chambers taken separately must always be greater than the absorption effected by a single column of the gas of a length equal to the sum of the two chambers. This conclusion is illustrated in a striking manner by the experiments; and it is further found that when the mean of the sums of the absorptions is divided by the absorption of the sum, the quotient is sensibly the same for all gases. It may also be inferred from considerations similar to the foregoing, that the sum of the absorptions must diminish, and approximate to the absorption of the sum, as the two chambers become more unequal in length, and that the sum of the absorptions of the two chambers is a maximum when the medial rock-salt plate divides the long tube into two equal compartments.

In these days a special interest attaches itself to the radiation of any gas through itself or through any other gas having the same period of vibration. The speaker referred to the results of an elaborate series of experiments on this interesting question. The experimental tube, 49·4 inches long, was divided into two compartments by a partition of rock salt. All external sources of heat were abolished, and the pile, furnished with its conical reflector, stood at the end of the tube. The compartment nearest the pile contained the gas which was to act as absorber, while that most distant from the pile held the gas which was to act as radiator. It is known that the destruction of the motion of a sensible mass of matter is always accompanied by the evolution of heat. A weight falling to the earth, and a ball striking a target, are heated on collision. The same is true for atoms, and in the present experiments the gas in the radiating chamber was heated by the collision of its own particles against the inner surface of the tube when they rushed in to fill the vacuum. The radiation was, in fact, what the speaker had named "dynamic radiation." The lengths of the two chambers were varied, the radiating column being lengthened and the absorbing one shortened at one and the same time; the sum of both was always the constant length 49·4 inches.

The experiments with the vapours were thus executed. Both the chambers into which the tube was divided were, in the first place, occupied by the vapour to be examined; the usual pressure being 1-60th of an atmosphere. The entrance of the vapour was so slow, and its quantity so small, that the radiation due to the warming of the vapour by its own collision was insensible. The needle being at zero, dry air was allowed to enter the chamber most distant from the pile. This air became heated dynamically, communicated its heat to the vapour, and the latter immediately discharged the heat thus communicated to it against the pile. It is quite evident, that not only does this case resemble, but that it is actually of the same mechanical character as that in which a vibrating tuning-fork is brought into contact with a surface of some extent. The fork, which before was inaudible, becomes at once a copious source of sound. What the sounding-board is to the fork, the compound molecule is to the elementary atom. The tuning-fork vibrating alone is in the condition of the atom radiating alone, the sound of the one and the heat of the other being alike insensible. But in association with sulphuric or acetic ether-vapour the elementary atom is in the condition of the tuning-fork applied to its sound-board, communicating through the molecule motion to the luminiferous ether, as the fork through the board communicates its motion to the air.

The experiments demonstrate the great opacity of a gas to radiations from the same gas. They also show in a very striking manner the influence of attenuation in the case of vapour. The individual molecules of a vapour may be powerful absorbers and radiators, but in thin strata they constitute an open sieve through which a large quantity of radiant heat may pass. In such thin strata, therefore, the vapours as used in our experiments, were generally found far less energetic than the gases, while in thick strata the same vapours showed an energy greatly superior to the same gases. The gases, it will be remembered, were always employed at a pressure of one atmosphere.

A few striking experiments were referred to in illustration of the influence of a paper lining, or a coat of varnish or lampblack, within the experimental tube. In dynamic radiation it is not possible to do entirely away with the action of the interior surface of the tube itself. When the tube is of brass and well polished within, the entrance of the air produces a deflection of 7·5 degrees, this being due to the emission from the warmed surface of the tube. A lining of paper, 2 feet long, raises the radiation sufficiently to drive the needle through an arc of 80 degrees, while a ring of paper, 1½ inches long, placed within the tube radiates sufficient to urge the needle through an arc of 56 degrees.

The speaker finally examined the diathermancy of the liquids from which his vapours were derived, and the result leaves no shadow of a doubt upon the mind, that both absorption and radiation are molecular phenomena, irrespective of the state of aggregation. If any vapour is a strong absorber and radiator, the liquid whence it comes is also a strong absorber and radiator. The molecule carries its power, or want of power, through all its stages of aggregation. The order of absorption in liquids and vapour is precisely the same; and the speaker looked forward with hope to the application of these results to other portions of the domain of thermotics.

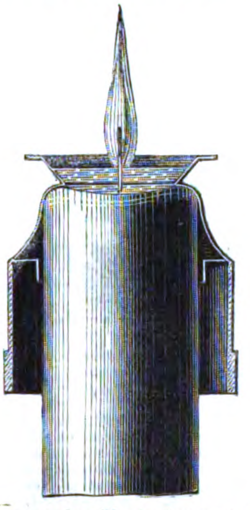
SINGULAR ELECTROLYTIC ACTION.

MR. ABEL, the Chemist of the War Department, lately communicated to the Chemical Society the results of his observations on the blistering of the lead coatings of a few of the iron projectiles commonly used in Sir William Armstrong's rifled ordnance. The shot consists mainly of cast-iron, and for the purpose of fitting tightly the bore of the gun, is coated with an alloy known as "soft metal," which consists of lead mixed with a small proportion either of tin or antimony; the steps of the manufacture being thus described:—According to one plan, the iron is turned down a little smaller than the required gauge, and then grooved out or "undercut" so as to present a number of projecting ridges by which the attachment of the lead is afterwards secured; it was then found that the unequal rates of expansion ultimately severed the connection of the two metals, and gave rise to inequalities upon the finished surface. These were, however, very different in appearance from the blisters which were discovered under some circumstances to be produced upon shot coated by the second or "galvanizing" process; to illustrate which Mr. Abel exhibited a photograph of the 110-lb. shot which was sealed as a pattern in November, 1861, and had been kept in a glass case since that time. Besides several small blisters, one of these measured 1·1 inch in width, and was raised about a quarter of an inch from the true surface. On puncturing this under water, a somewhat considerable volume of gas escaped, which on careful examination proved to be pure hydrogen, and on comparing then the bulk of gas collected, with the internal capacity of the blister, it was found to have existed under a pressure of ten atmospheres. Reverting now to the process of manufacture, the origin of this gas would become apparent. The iron shot were turned flush, and coated with zinc as preliminary to the attachment

of lead; this was accomplished by heating the projectiles directly they left the lathe, in an oven which was graduated so as eventually to impart a temperature nearly that of the fusing point of zinc; they were dipped for a moment into a solution of sal-ammoniac, and then immediately into a bath of melted zinc; from this they were passed directly into a bath of "soft metal," which adhered perfectly to the galvanized surface, and this coating could then be increased to any extent by supporting the shot in a mould and pouring the lead alloy around it. Among a vast number of Armstrong projectiles which had been made in this manner, a very small proportion only exhibited the peculiarities described, and no practical inconvenience had been felt sufficient to warrant a change in the process, since these blisters when observed might easily be punctured and flattened down, the small orifice being afterwards closed with solder. It was evident that water, or some hydrogen compound must be enclosed at an early stage of the process, and afford by its electrolytic decomposition, the gas which, gradually accumulating, exerted the disruptive action already noticed. In tracing its probable origin, Mr. Abel discovered that chloride of zinc, when once combined with water, could not be again rendered perfectly anhydrous by exposure to a degree of heat somewhat above the melting point of zinc; for on throwing fragments of zinc into the fused chloride they were quickly melted, giving rise to the production of hydrogen gas, and the formation of an oxychloride of the metal. It was not difficult to suppose a similar change occurring in the lapse of time at the ordinary temperature; chloride of zinc would undoubtedly be formed by the action of the sal-ammoniac flux upon zinc or its oxide, and this might readily attach itself to slight asperities upon the surface of the shot, become hydrated, and ultimately enclosed within the lead coating. The torn, fibrous aspect of the metal on the inner surfaces of the blister, and the detection of chlorine in the cavities, confirmed these opinions, and pointed directly to the origin of these remarkable appearances upon the Armstrong shot.

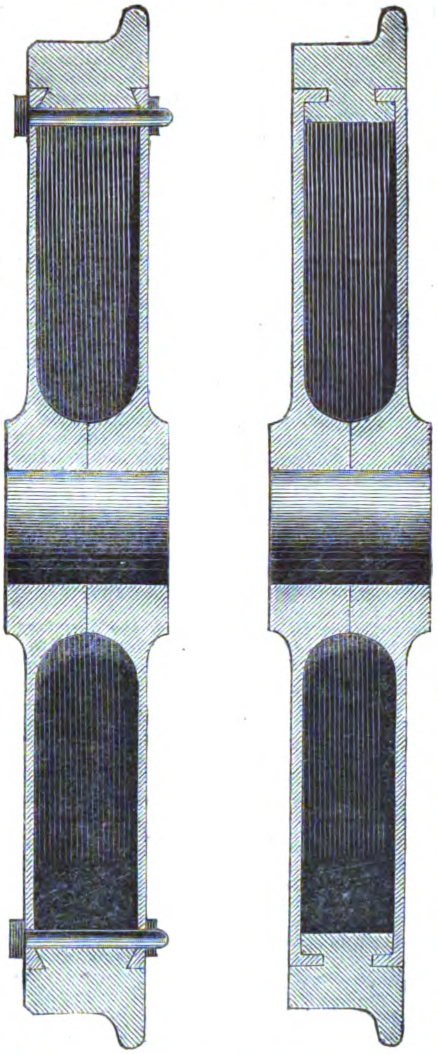
The President expressed his surprise on hearing that so thin a coating of lead had effectually prevented the diffusion of the hydrogen.—Dr. Franklin inquired whether these blisters appeared at once, or only after the lapse of time.—Mr. Abel replied that the whole of these projectiles had passed an inspection before being received into store, and that it was only on subsequent examination that the faults were noticed. Some few instances were reported from distant stations, and all were doubtless the work of time.

CHARLES' CANDLE NOZZLE.



THE above engraving illustrates a candle nozzle of an improved form, just patented by Mr. A. P. Charles, of Wapping. The invention consists of a cap or nozzle to fit over a candle; it is furnished with a cup or reservoir to contain the melted tallow. As the candle burns downwards, the nozzle descends by its own weight. The wick being very thin, when blown out can be readily relighted, which is not the case with candles known as "night lights." The candles may be of any length. The nozzle is particularly adapted for candles burning in candelabras, halls, &c.

WILSON'S RAILWAY WHEELS.



THE invention, shown in the above engravings, relates to a peculiar construction and arrangement of railway wheels, whereby greater economy and simplicity of construction are combined with increased safety in cases of fracture of the tyre. The invention has been patented by Mr. E. B. Wilson, of Parliament-street.

Two discs of the desired size are first prepared by forging or casting, and are then placed in dies and subjected to compression or hammering therein for the purpose of giving them the desired form, whether flat, dished, or corrugated. These dies are also so shaped as to produce a raised annular rim all round the circumference of the discs on one side thereof, such rim being either parallel, V-shaped, or of any other sectional form. The tyre has corresponding annular grooves formed inside it, so as to fit accurately over or on to the rims of the two discs which are placed inside the tyre from opposite sides thereof, and may or may not be held therein by bolts passing through the discs. The space between the discs may be filled in with india rubber, cork wood, or other good sound deadening material. The discs may be cast in steel or malleable metal, or made of "uses" under the steam hammer, and then rolled by means of conical rollers. The compressing, hammering, or rolling of the discs and tyre may be done at the time of casting or forging or subsequently by re-heating.

A gentleman resident in Cuba informs us that the utmost activity prevails there with regard to laying out of new properties and the erection of steam machinery, and that at least 25,000 slaves have within the last year been imported from Africa.

TO CORRESPONDENTS.

RECEIVED.—A. B.—G. R. F.—B. Brothers.—F. A. P.—J. N.—W. B.—L. S. M.—J. N.

B. BROS. (Newport, Mon.)—Please address Mr. Holdway, carriage builder, Mount-street, Grosvenor-square, W. There are other parties engaged in this business, but we do not know their exact addresses. Since writing the article on *titaniferous iron ores*, we have ascertained, from a source upon which we can rely, that iron ores in a similar state of aggregation—that of minute subdivision—have been successfully reduced in France, by working them up into balls with clay, to be afterwards smelted in the blast furnace.

NAUTICUS.—We have received a letter from this correspondent, in which he expresses surprise that the merits of Mr. Vaile's propeller have not been discussed by other correspondents in our pages. He goes on to say, "I must confess that I should like your correspondents to be as candid in relation to Mr. Vaile's propeller as you yourself have been. Possibly your insertion of this brief note of interrogation may lead to a response."

W. B.—Your invention is not new. It has been patented as a mine-pump valve (for which it has failed) two or three years ago.

W. ROBERTS (Millwall).—We have received a letter from this gentleman stating that he had steam first at Sydenham, and that the quantity of water which he lodged in the large tank during the first hour was exactly 20 in., precisely the same performance as Shand's large engine.

T. O. F.—We have not received the sketch which explains your letter, and cannot express any positive opinion till we do. As far as we can judge, the first invention seems good.

A. MUNTZ.—We scarcely understand the drift of your letter. Please explain what you want us to do.

Correspondence.

[*We do not hold ourselves responsible for the opinions of our correspondents.*]

VAILES' PROPELLER.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—From a careful perusal of your excellent article on "Marine Engine Improvement," which appeared in the MECHANICS' MAGAZINE of the 12th ult., and also your remarks on the pamphlet lately published by Mr. Vaile, describing his system of propulsion, as well as an attentive examination of the pamphlet itself, I am convinced, somewhat against my prejudices, that his propeller is adapted to forward those improvements in marine engines which you advocate.

Any one who has read that pamphlet, cannot fail to have noticed that all the useful effect of a 40 ft. paddle-wheel can, on the principles there advocated, be produced by chain-wheels only 5 ft. in diameter, thus reducing the leverage against the engines from 20 ft. to 2 ft. 6 in.

Now, assuming any number—say 5 tons—as the actual pressure of the water on the float of a 40 ft. paddle-wheel when the ship is making 14 knots, then it follows, supposing the same ship to be fitted with Vaile's propellers, having floats of similar areas, that the pressure on their floats would also be 5 tons when the vessel was moving at the same rate of speed. But here is the important difference between the two propellers: in the paddle-wheel this pressure of 5 tons would be at the end of a 20 ft. leverage against the engine, while in the Vaile propeller it would be at the end of a leverage of only 2 ft. 6 in.

A pair of these propellers, so constructed that each of their floats should contain half the area of the largest screw propeller made, and consequently the two together equal its entire area, would form a compact propelling apparatus, not requiring chain-wheels of more than 3 ft. in diameter, and a space of 5 ft. from centre to centre of their shafts; such a space between the shafts would give to each float, while in the act of propelling, a continuous horizontal stroke of 5 ft.

From these comparisons of the new propellers with the paddle-wheel and screw, it will be readily seen, that exceedingly small engines may be used to drive it, and thereby both steam-power and stowage room in the vessel saved, and great economy in the first cost and working of the engines effected. A pair of such propellers, driven by separate engines of the locomotive class, would, I think, produce good results, not the least of which would be the

steering power gained by the independent action of the engines and propellers, and also a better distribution of steam power round the shaft when steaming ahead, which would be obtained by arranging the cranks on the shafts of each engine at such angles that, when connected by the intermediate shaft, it would form a four-throw shaft, no two cranks of which would be at their dead points at the same moment of time.

I can see no reason why such chains as are shown in the pamphlet should not be driven at high rates of speed. The pins connecting the rods, of which the chain is formed, can be made of large diameter, and the bearing surface for these pins, in the rods, can be made of any required breadth, so that ample provision is obtainable for all possible wear-and-tear.

I am, Sir, your obedient servant,

Observer.

Miscellanea.

We learn that the Hamburgh show is likely to prove a great success. The number of animals entered is 8,800, and of implements 1,500.

The hinges of the new oaken door lately put up at Hereford Cathedral cost £140, and were executed by Porter, of London.

We learn from the *Times* that orders have been received at the head-quarters of the Royal Engineer establishment, Chatham, from the Horse Guards, directing a number of the most experienced telegraphists, who have completed their course of instruction at the School of Telegraphy, Brompton Barracks, to be selected from the companies at head-quarters, to be despatched to Turkey to assist in laying down a telegraph line through that country and Persia, to India. It is expected that the expedition to be despatched from Chatham will be occupied for about five years in the undertaking.

An important survey of guano deposits on the coast of Peru has been concluded, and the stocks are estimated at 1,500,000 tons on the Macabi islands, 2,500,000 tons on the Guanape group (opposite the point of St. Helena), and 4,000,000 tons on the Lobos island, representing a total value of 230,000,000 dollars, or £46,000,000 sterling. There is every probability of a magnificent dock being speedily erected at Callao, which will be the clearing port for guano vessels from all these islands.

At the close of the year 1862 there belonged to the ports of the United Kingdom 28,440 vessels of 4,934,400 tons, usually navigated by 228,139 men and boys—an increase in the course of the year of 402 vessels, 127,574 tons, and 3,315 men and boys. The vessels belonging to the British plantations were 10,967, of 1,107,696 tons, and manned by 75,934 persons.

The Royal yacht "Osborne" made an official trial of her machinery on Wednesday at Portsmouth. She has been fitted with new feathering wheels by Messrs. Maudslay and Field. The speed attained by the yacht is nearly three-quarters of a knot in excess of what she realized when a new vessel 20 years since, and the trial may therefore be considered in the highest degree satisfactory.

A Joint-Stock Association, under the title of the Lancashire Steel Company (Limited), have arranged with Messrs. Bessemer and Longsden to work their patents on payment of certain royalties upon the steel produced. They propose to erect suitable buildings, furnaces, blast engines, converting vessels, hydraulic cranes, steam hammers and rolling mills, capable of making a single block of steel of 10 tons weight, and of producing 200 tons of steel per week, adapted for rails, locomotive engine tyres, axles, crank shafts, marine engine shafts, piston rods, shafting, boiler and ship plates, cannons, mortars, girder bridge plates, &c., and for all purposes where it is desirable to substitute Bessemer steel for iron. It has hitherto been rather disgraceful to English enterprise that we were unavoidably compelled to send to the Continent for the larger proportion of our heavy steel forgings or castings. We wish the company every success therefore, and trust that it will efficiently supply a want long felt.

A prospectus has been issued of the Newport (Monmouthshire) Dry Dock Wood and Iron Shipbuilding and Ship Repairing Company, with a capital of £100,000, in shares of £20. Mr. Crawshay Bailey is the chairman, and the object is to purchase some existing works and greatly to extend the shipbuilding trade of the port of Newport.

Dr. Haines, of Grant College, Bombay, describes the occurrence in vast quantities of naturally formed carbonate of soda in the neighbourhood of Aden. The substance as found contains 50 per cent. of natural carbonate, and occurs along the coast, for ten miles at least to the east of Aden, in hollows behind high-water mark, to which the sea has access by percolation. Its formation is attributed to the percolation of the sea-water through the fragments, and pebbles of limestone constituting the shingle of the shore, probably by the partial interchange of elements between the salt or chloride of sodium and the carbonate of lime giving rise to the production of chloride of calcium and carbonate of soda. It is surmised that the formation of carbonate of soda may go on along the whole thousand miles of the south-east Arabian coast.

On Friday last a barque named the "Virginia" was launched at Liverpool from the building yard of Mr. John Robinson, south side of Duke's Dock. The launch, though attended with some apparent difficulty, consequent on the marked difference between the level of the building yard and the river, a height of ten feet, was accomplished in perfect safety. The "Virginia" is a ship of somewhat peculiar construction, the principle having been patented. Her bottom is flat, and she has three keels, in addition to which only straight timber is employed in the building. Her length is 115 ft., beam 23 ft., and depth of hold 12 ft. Her registered tonnage is 200 tons, but has carrying capacity equal to 500 tons, and is classed for seven years at Lloyd's. The time occupied in building the "Virginia" was only 40 days and 40 nights, and she was launched with her masts and a portion of her rigging fitted.

On Tuesday night Mr. Ferrand gave notice that he would, on Thursday next, ask the Secretary for the Home Department, whether his attention had been drawn to the great destruction of life by the constant bursting of steam boilers, especially by the bursting of one near Leeds a few days ago, when ten people were killed; and, if so, whether steam boilers ought not to be placed under Government inspection. In a recent leader we advocated such a supervision, and we are pleased to see that the attention of Government is about to be called to the matter.

The directors of the works of the Modane and Bardonèche tunnel have published their report at Turin. It appears that at the close of 1862 the total length of the tunnel pierced was 2,199 metres, viz., 1,274 on the Bardonèche, and 925 on the Modane side. The measures taken for increasing the supply of compressed air were successful. As regards the time necessary for completing the work, the directors express a belief that it will be considerably shorter than 12½ years, the limit lately calculated by the Minister of Public Works. The convention with France allows 25 years. The total length of the tunnel being 12,220 metres, the expense, calculated at 4,000f. per metre, will amount to about 50 millions of francs. The railroad from Bardonèche to Sussa will be 40 kilometres in length, with a gradient of 19·325 per 1,000, and 6,500 metres through tunnels, the longest of which, near Exilles, will measure 1,170 metres.

During his speech on Tuesday week, in the House of Commons, upon the Board of Works, Mr. B. Cochrane mentioned the fact that it had been proprosed to place a floating light on the Little Basses Rocks, Ceylon, and that an hon. member had recently stated:—"These rocks were in the direct line of the steamers between Point de Galle and Madras, and as early as 1826 it was represented to the Government that they ought to be lighted. In 1848 the Government made up their minds to do something, and wrote to Ceylon for advice how lighthouses could be erected. Six years afterwards, in 1854, they got reports showing that floating lights were impracticable, and strongly recommending the building of light houses on both the Basses Rocks for the estimated sum of £4,500. In 1855, Parliament voted £3,000; in 1856, £17,000, and £6,000 for a steamer to carry the materials; in 1857, £8,000; in 1858, £10,000; and in 1859, £10,000, making a total of £54,000, for which there was never any other estimate than the one of £4,500. The lighthouse was not put up, and he saw it on the wharf at Point de Galle. In 1860 they were told that they could not put up a lighthouse, and that they must have a floating light, which was in the first instance condemned. Accordingly, in 1861 the House voted £8,000, and in 1862 £2,000 more for a floating light. The money was not expended, and now they were asked to vote £8,000." The whole of these sums, said Mr. Cochrane, made a total of £80,000; and the proceeding appeared to be most reckless and extraordinary.

A contemporary describes a most ingenious machine, for registering music instantaneously as played, invented and patented by Mr. Beverley Fenby, of Bute Villa, St. John's, Worcester. It will afford to the composer, whether professional or amateur, the means of instantaneously recording his ideas in an enduring form and as plainly intelligible as the usual printed musical books. The machine is small, and the motive power is electro-magnetic, produced by a voltaic battery, and working in a manner analogous to the printing telegraph. The machine having been placed *en rapport* with the instrument to be played upon, say painoforte, harmonium, or organ, the player manipulates the keys in the usual manner, and the machine prints his performance as he goes along, at a speed proportionate to his playing, the usual rate being 15 in. of paper per minute. The printed notation is identical with that already in use, the only difference being that the heads of the notes are square instead of round. The sharps, flats, ledger lines, and every musical sign, are the same as those used for the piano and organ. The printing is clear and well defined, and the performer feels not the least impediment or hindrance to his playing, from the machine, however rapid and complicated his style may be. The machine and battery are very compact, and the whole is enclosed in a case; the only communication between it and the keys of the piano are the wires of the battery, which are touched by a small key and spring fixed beneath the keys. The case can be placed either by the side of the piano or in another room at whatever distance, so long as there is the communication by the wires. The performer composes, plays, and prints at one and the same time.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgment:—

Steam Engines, &c., 3294, 3337, 3340.
Boilers and Furnaces, 3307.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 3316, 3339, 3343.
Ships and Boats, including their fittings, 3332, 3333, 3344.
Cultivation of the Soil, including agricultural implements and machines, 3325, 3338.
Food and Beverages, including apparatus for preparing food for men and animals, 3296, 3299, 3308, 3323, 3324, 3342, 3345, 3348.
Fibrous Fabrics, including machinery for treating fibre, pulp, paper, &c., 3301, 3306, 3313, 3319, 3321, 3329, 3330, 3336, 3341, 3346, 3347.
Buildings and Building Materials, 3303, 3320, 3327.
Lighting, Heating, and Ventilating, 3291, 3302, 3317, 3334.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 3309, 3311, 3315, 3328.
Metals, including apparatus for their manufacture, 3293, 3305.
Chemistry and Photography, 3298.
Electrical Apparatus, 3292, 3331.
Warfare, 3297, 3300, 3304, 3326, 3335.
Letter-Press Printing—*none*.
Miscellaneous, 3295, 3312, 3314, 3318, 3322.

3291. J. Hilliar. *Improvements in ventilating, and in the exclusion of dust or draught, insects, or other animals, from apartments, carriages, or other confined spaces.* Dated December 8, 1862.

These improvements in apparatus for obtaining ventilation in buildings, apartments, carriages, beds, and other like confined spaces, whilst excluding therefrom all dust, draught, insects, or other animals, comprise the employment of rolling bands or screens of wire gauze, in one thickness or more, in manner described. *Patent completed.*

3292. E. T. Hughes. *Improvements in galvanic apparatus.* (A communication.) Dated December 8, 1862.

This invention consists of various improved arrangements of galvanic apparatus adapted to every part of the human body. When applied to the head, the patentee employs a wig-spring, and solders to one end a silvered copper plate, of any required size and shape, having a shallow cavity formed in it for containing a conductor, consisting of several folds of flannel sewed together. On the rim outside the cavity he places a ribbon of silk, and fastens it to the conductor, over which and the silk he places a zinc plate, and clasps its edge by the rim of the silvered copper plate, the said zinc plate fitting the part of the head against which it is to be placed. The two plates are insulated by the silk between them, and the double folded rim is pressed air and water tight. The same construction is applied to the other end of the spring, but the

plates are changed—that is, the plate having the cavity is formed of zinc and the plate which fits the head and covers the conductor and insulator of silvered copper plate. At the top of each cavity there are two openings, one larger than the other—the larger for the passage of the fluid for moistening the conductor, and the smaller for allowing the air to escape—which openings are to be perfectly closed when the cavity is filled. The fluid employed is vinegar or dilute sulphuric acid, either of which may contain a small quantity of weak alcohol to enable the fluid to be quickly imbibed by the conductor. When both conductors are moistened, the development of electricity is immediately perceived by the cracking noise, and when the inner plates are fitted in opposite positions against the head, the galvanic current passes through it. *Patent completed.*

3293. J. A. and C. L. Kirsling. *Improved means of renewing worn-out and partially worn-out files and rasps.* Dated December 8, 1862.

This invention consists in the judicious employment of different acids to act on the said files and rasps after they have been washed or made perfectly clean. *Patent abandoned.*

3294. J. H. Johnson. *Improvements in the construction of steam generators.* (A communication.) Dated December 8, 1862.

This invention relates more particularly to multitubular boilers or steam generators, and comprises also an improved construction and mode or method of fitting or adjusting the tubes in the tube plates, whereby greater facility is afforded for introducing, removing, and cleaning the same. The tubes, when secured in their places, according to this invention, are not contracted or obstructed by the pressure of any internal rings or ferrules, so that the cleaning of the same is more easy of execution, and the draught is impeded. The details of this invention are voluminous. *Patent completed.*

3295. T. Wingate, jun. *Improvements in dredging machinery.* Dated December 9, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3296. V. Mirland. *Improvements in manufacturing paste with the dried pulp of rhubarb to be used as preserve.* Dated December 9, 1862.

This invention consists in applying the principle of preservation by dessication to the manufacture of a paste from the petioles and fibres of fresh leaves of the plant called rheum or rhubarb, which paste the patentee terms rhubarb preserve; the said preserve, mixed with sugar or combined with aromatic essences, can be substituted for the fresh fruit in all its uses. *Patent completed.*

3297. M. F. Benton. *Improvements in the manufacture of gunpowder.* (A communication.) Dated December 9, 1862.

This invention is carried out as follows:—The first kind of powder is made from the following ingredients, in or about the following proportions; that is to say, 38 parts in weight of water, and 2 parts in weight of finely-pulverized charcoal are taken and boiled together, so that the charcoal may become dissolved. Then there are to be added 20 parts in weight of chlorate of potash, 6 parts in weight of a mixture composed of 4 parts in weight of half-calcined sea grass, and 2 parts of finely pulverized stone coal. By this addition the boiling will become interrupted, which must be restored, and then there must be added 7 parts in weight of sawdust, and the whole must be well boiled together so as to form a solution. The second kind of powder is made by taking 20 parts in weight of water and 1 part in weight of pulverized charcoal, and boiling them together until the latter is dissolved. Then there are added 10 parts in weight of chlorate of potash, and the boiling is repeated, after which there are added 5 parts in weight of half-calcined sea grass, and ¾ of a part of pulverized stone coal. The boiling which was interrupted by the latter addition is restored, and then there are added 4 parts in weight of sawdust, and the whole of the ingredients are well boiled together so as to form a solution. *Patent abandoned.*

3298. W. Clark. *Improvements in photographic apparatus.* (A communication.) Dated December 9, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3299. R. A. Brooman. *Improvements in treating liquorice root to obtain liquid and solid extracts therefrom.* (A communication.) Dated December 9, 1862.

The extracts hitherto obtained from liquorice root have been black, and when eaten have produced in the mouth a yellowish-brown saliva with a sweet, but somewhat tart, flavour. Now the object of this invention is to make the extracts, whether liquid or solid, without any apparent colour, and without the tart flavour. The invention consists in treating the root of the liquorice plant as hereafter stated. The roots are first pulverized by pestles, stones, or rollers, or they are cut up into pieces, and are washed and soaked in cold water until they are thoroughly exhausted. The resulting waters are thick and troubled; and, in order to clarify them, they are boiled, say for about ten minutes, and then strained through a woollen strainer, which retains the matters coagulated by the boiling. The liquid is then limpid, and of a dark yellow colour, and to remove this colour the liquor is placed in a filter containing animal black. The liquid, after having been acted on by the black, may be evaporated to any desired consistence, allowed to cool gradually, when it becomes a pretty firm mass, and may be made into sticks and other forms. *Patent abandoned.*

3300. G. Jeffries. *Improvements in breech-loading firearms.* Dated December 9, 1862.

This invention refers to a previous patent, dated the 2nd of January, 1862, and comprises an arrangement of parts whereby the patentee is enabled, in firearms which turn sideways, to employ a flat breech-plate at right angles to the centre line, without the inconvenience arising from an axis placed out of the centre line of the piece. *Patent completed.*

3301. J. Howard, J. Bullough, and T. Clegg. *Improvements in machinery or apparatus for preparing cotton or other fibrous materials to be spun.* Dated December 9, 1862.

This invention relates to the machine or apparatus generally called the opener, scutcher, or blower, and its object is to clean the cotton or fibrous material as it passes between the beater or cylinder and the dust cages more effectually than it has hitherto been accomplished. Instead of the ordinary grid bars having curved surfaces at the top, and narrow spaces between them, the inventors employ two with acute edges at the top by forming them of a triangular shape, and they place them at such distances apart as to allow the passage of the heaviest dirt or refuse. Against the under edges or surfaces of the bars they place one or more dampers or false bottoms, connected by brackets to arms or levers in contact with cams or tappets which are moved periodically so as to open the dampers for the removal of the dirt, and close them to prevent the passage of the cotton or material. *Patent abandoned.*

3302. J. M. and E. D. Sykes. *Improvements in deodorizing petroleum, shale, and other like oils.* Dated December 9, 1862.

To a quantity of petroleum, shale, or other like oils the inventors add sulphuric acid, and agitate the mixture for some time. They then add oxide of manganese, and again continue the agitation. After the mixture has been allowed to "work" for some time, and when it has settled, they draw off the pure oil, and wash it with lime water in the ordinary way, or wash it by any of the processes at present in use. The residuum in the bottom of the vessel may be added as found most convenient. *Patent abandoned.*

3303. P. Effertz. *Improvements in machinery or apparatus for making bricks, tiles, drain pipes, and other similar articles.* Dated December 9, 1862.

The nature of this invention—which is a farther improvement on a patent granted to the present patentee bearing date the 5th day of September, 1861 (No. 2211)—consists in using three or more rollers for mixing the clay or plastic material. When three only are used, he places two of them in a vertical line under one of the others. He drives the surfaces of the said rollers at different speeds, the first horizontal roller having the lowest speed, and the bottom one the greatest. The variations of speed may be obtained by making the rollers of different diameters, or by giving each of them a different number of revolutions per minute, or by both means combined. He also leaves a greater space between the two horizontal rollers than between the second horizontal roller and the bottom roller, and causes the rollers to revolve in opposite directions. The said rollers run in bearings fixed on framework, and between two side plates, forming a channel provided with scrapers or doctors to clear the adhering clay from the rollers. The clay or material is forced into the channel by the rollers, and the side plates are provided with a die or shaper through which the clay or material is forced in the desired shape. *Patent completed.*

3304. W. E. Newton. *Improvements in firearms.* (A communication.) Dated December 9, 1862.

This invention has for its object to simplify the construction of firearms, by reducing the number of separate pieces of which the arm is to be composed. This object is effected by constructing the separate parts in such a manner as to cause each single piece to perform the offices of two, three, or more of such pieces as are used in ordinary firearms to effect the desired object. For instance, in an ordinary musket, the lock (including the two screws for securing it to the stock) is composed of fourteen pieces, whereas the lock which forms the subject of the present invention is composed of only three principal parts—viz., the hammer, the lock-plate, and the spring. The screw of the lock-plate is made to serve also to secure the lock to the stock, and for holding the hammer. The spring is provided with a stud which fits in a hole in the lock plate, and is thereby held in place, and at tension. The outer end of the spring has two notches made in it, for the purpose of receiving a cam piece, which is fixed on the inside of the hammer. The other end of the spring also acts on the hammer, which is relieved by means of the trigger from the notches at the first-mentioned end of the spring. *Patent completed.*

3305. E. B. Wilson. *Improvements in machinery or apparatus for rolling metals.* Dated December 9, 1862.

This invention relates to a peculiar construction and arrangement of conical rolling mill, and consists in driving one roll direct from the main shaft by a pair of bevel wheels, another pair of bevel wheels being also employed for driving the other roll direct from the first roll; one of the rolls is adjusted either by the aid of a cam or hydraulic power. The framing of the rolling mill is of course peculiarly adapted to suit this arrangement, either vertically or horizontally. *Patent abandoned.*

3306. J. Lamb. *Improvements in the manufacture of tissue paper for transferring patterns and designs.* Dated December 10, 1862.

This invention consists in combining the size with the pulp in the ordinary rag engines or other machinery now employed in preparing the pulp for the paper-making machines, or in combining the size with the water with which the pulp is diluted previous to, or when it is supplied to, the paper-making machines, or in sizing the paper in its progress through the paper-making machine. *Patent abandoned.*

3307. W. Inglis. *Improvements in steam boilers.* Dated December 10, 1862.

This invention relates to improvements in steam boilers designed more particularly for generating steam of moderate pressure, and consists, generally, in constructing the boiler with a high furnace, combined with a down draught, and an arrangement of parts whereby the water in the boiler is made to circulate rapidly, and in a direction opposite to the course of the furnace gases. This invention cannot be described without reference to the drawings. *Patent completed.*

3308. L. A. Lesage. *Making and moulding fruit, jellies, and preserves.* Dated December 10, 1862.

This invention consists in solidifying fruit, jellies, and jams, by means of apple juice, in moulds. The inventor prefers using the juice of the apple called in French the pigeonnet, although other kinds will answer the purpose. The jellies and jams thus made cannot be differently coloured and perfumed with the required aroma, and are made in moulds of any suitable material, which may have separations, in order that the same jelly may receive different flavours and colours. *Patent abandoned.*

3309. J. R. C. Taunton. *Improvements in the manufacture and ornamentation of metallic bedsteads and other articles of like manufacture.* Dated December 10, 1862.

This invention consists—1, in manufacturing the pillars of metallic bedsteads and other articles of like manufacture by casting the said pillars of malleable cast iron, or of brass, in the following manner:—The inventor casts the pillar and corner block (without the dovetail socket) and the leg all in one piece, the casting being hollow or tubular. He effects the casting in sand wholly cored with a sand or loam core, as ordinarily employed in making hollow castings. The ends of the pillar and leg may either be cast opened or closed. When they are cast open at the ends, the said ends are provided with top and bottom mounts, which may either be cast on the said ends by means of chills or iron moulds, or cast separately in sand or chills, and afterwards fastened on the ends. The dovetail socket of the corner block is cast in the following manner:—He makes hollows in or projections on the corner block, the said projections having heads, and the said hollows being of such a figure, that metal cast in them will be fixed therein. Over these hollows or projections, he places chills or iron moulds, having internally the figure of the dovetail socket of the joint. Into the said mould he runs molten iron, and thereby casts upon the corner block the dovetail socket required to affix the side of the bedstead to the pillar, the said dovetail socket being secured to the corner block by being cast upon the projection on, or engaging in, the hollow or recess in the corner block. This invention consists—2, in ornamenting metallic bedsteads and other articles of like manufacture in the following way:—He casts ornaments of iron, brass, or other metal on the outside of the angle iron or other frame of the bedstead or other article, or on any other part of the bedstead or article which it may be wished to ornament. At the parts where the ornaments are to be cast, he rivets or screws rivets or screws having heads; or he makes a hole or holes at those parts. When the ornaments are cast upon those parts, they are fixed by being cast upon the heads of the rivets or screws, or by a part of the molten iron running through the holes, and forming heads on the side of the frame opposite to that which is ornamented. When the ornament is attached by means of the holes described, chills or moulds are placed on either side of the place where the casting is effected, so as to form the ornament on one side and the head on the other. *Patent abandoned.*

3310. S. B. Whitfield. *Improvements in the dovetail joints used in metallic bedsteads and other articles of like manufacture.* Dated December 10, 1862.

This invention consists in making the taper-piece, or "he-dovetail" of the said dovetail joint, either of ordinary wrought iron or of the annealed cast iron called malleable iron. In making the said "he-dovetails" of wrought iron, the patentee shapes them by the stamping or forging process, and in making them of annealed cast iron, he casts and anneals them in the ordinary way. In either case he makes a connecting-piece on the said "he-dovetail," by which to connect it to the block of the joint. The said connecting-piece may either be of a conical figure, its axis being parallel to that of the "he-dovetail," by tapering in an opposite direction; or it may be of an angular or other figure. The "he-dovetail" of wrought or malleable iron may be connected to the cast-iron block on the end of the rail by the said block being cast on the end of the rail, and on the connecting-piece of the "he-dovetail" at the same time. Or the said block may have a recess cast in it into which the connecting-piece of the "he-dovetail" may be placed and fixed. *Patent completed.*

3311. M. Osborne. *Improvements in the manufacture of cast-iron fenders.* Dated December 10, 1862.

This invention consists in certain improvements whereby the fronts of cast-iron fenders are cast upon the ends of the fenders, so as to secure the ends to the fronts, by which improvements the fastenings ordinarily employed to connect the ends and fronts of the fenders together are superseded. *Patent completed.*

3312. A. P. Price. *Improvements in the manufacture or production of colours.* (A communication.) Dated December 10, 1862.

This invention has for its object the preparation of blue colours which are obtained as follows:—The inventor takes a compound or combination of aniline, consisting of aniline combined in equivalent proportions with any of the following acids, namely—acetic, valerianic, lactic, benzonic, cinnamic, tartaric, and oxalic acid, such compounds being either obtained by, or resulting from, direct combination of equivalent proportions of acid and aniline, or obtained by means of, or resulting from, double chemical decomposition, as is well understood by chemists. He mixes any one of these compounds or combinations so resulting or obtained, or mixtures of them, with the substance known in Germany and France as fuchsine, and corresponding with those products obtained from aniline known in this country as magenta and roseaniline, and he heats the same together by preference at a temperature of from 160 deg. to 190 deg. centigrade, until the desired blue colour free from violet is produced. *Patent completed.*

3313. D. Chalmers. *Improvements in the preparation or manufacture of textile materials, and in the machinery or apparatus used therein.* Dated December 10, 1862.

This invention relates to the arrangement and construction of winding, copping, or balling machines, such as are used in the manufacture of flax and other textile materials, as well as to the shuttles employed in weaving. In the im-

proved winding machine, the winding or balling spindles are disposed in an angular, diagonal, or horizontal position, or they are inverted for the purpose of taking advantage of the weight of the spindle for hardening the cop or pin. The object of the diagonal or horizonral spindle arrangement is to enable the attendant to doff or take off the cop with greater ease. The spindles each work through a tube and stuffiing box, so as to throw the desired friction or weight upon the spindle, and thus dispense with the use of levers or weights. *Patent completed.*

3314. W. A. Turner. *Improvements in machinery for cutting and paring starch.* Dated December 10, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3315. W. Clark. *Improvements in umbrellas.* (A communication.) Dated December 10, 1862.

This invention relates to an improved umbrella and cane combined, according to which an umbrella may be applied to or separated from an ordinary walking stick, which can be used alone, as usual. The principal features of this invention are—1, the handle or stick of the umbrella has no openings or slits made in it for applying spring catches, which are dispensed with, and the stick is for this reason much stronger and of simpler and readier construction than the ordinary stick; 2, the umbrella can never be turned inside out by the wind; 3, it opens without difficulty by means of a peculiar arrangement of the ribs. An improved mechanical arrangement is also applied for securing the umbrella in a closed position, as also for reducing its length one half without rendering it inconvenient. The invention cannot be described without reference to the drawings. *Patent completed.*

3316. J. King. *Improvements in apparatus used for signalling on railways.* Dated December 10, 1862.

For the purpose of this invention, at intervals along a line of railway, telegraphing stations are erected containing ordinary clock-work, capable of rotating a pointing instrument, suitable when brought into position to be acted upon by the clock-work, and thus to indicate to the driver of the next train within what period (within a given time) the preceding train has passed the station. *Patent completed.*

3317. E. Toynbee. *Improvements in extracting oils and fatty matters from shoddy or refuse wool, skins, or skin pieces, glue pieces, cotton waste, and other animal or vegetable matter, and in producing an artificial manure.* Dated December 10, 1862.

Here the fibres or substances are boiled in sulphuric acid until the whole dissolution of the fibre is effected. Steam is then admitted into the vessel to cause the oils to rise to the surface, from whence they are collected for distillation. During the distillation properly prepared phosphates are added; the liquid compound is now run off into a drying material, either organic or inorganic, and a highly nitrogenized and phosphatic compound is obtained, and which forms a valuable manure. *Patent completed.*

3318. J. Speight. *Improvements in horse-hoes.* Dated December 11, 1862.

This invention relates to improvements upon a patent granted to the present patentee on the 29th day of March, 1859, No. 786, for "improvements in horse-hoes," and refers particularly to a method of regulating the depth at which the hoes work when used on uneven ground, such as hill sides, or on ridge land. In the former specification the hoes were described as being attached to levers connected with a revolving shaft working in a slide frame having bearings at each end, and which shaft could be raised or lowered as required for different kinds of corn or roots. The present improvement consists in suspending the shaft or bar to which the hoes are attached upon a bearing at its centre, instead of at each end, so that when one end is raised by turning a handle or otherwise, as described in the former specification, the other end is lowered in a corresponding degree, and thus when working over ridged or curved surfaces, or along what are called "lands," the depth or bite of the hoes may be regulated by the attendant with the greatest nicety. *Patent completed.*

3319. W. Tristram and H. Brereton. *Improvements in machinery or apparatus for sizing yarns and threads.* Dated December 11, 1862.

These improvements are applicable to the machines known in the trade as "slashers" and tape machines, which machines are employed for sizing and drying yarns and threads, and winding them on to beams. The invention consists in the application of a revolving brush which acts on the yarn or thread immediately after the yarn or thread has passed the rollers by which the size is applied, and by which the surplus size is squeezed out; the brush rotates rapidly, and the yarn or thread is pressed into the bristles by means of a rod connected to a swing frame, the position of which can be varied so as to increase or reduce the depth to which the yarn is pressed into the bristles. Below the revolving brush is another brush which revolves slowly in a trough containg soap and water, or other liquid for clearing the brush acting on the yarn or thread, and keeping it moist. *Patent completed.*

3320. J. R. Breckon and T. Douglas. *Improvements in the manufacture of fire-bricks and other articles usually made from fire-clay.* Dated December 11, 1862.

This invention consists in making fire-bricks, and other articles usually made from fire-clay, of the fire-stone called Ganister, as it is found in the coal fields in the counties of Durham and Northumberland, combined with the ordinary fire-clay, as they are obtained from the coal measures of the two aforesaid counties. *Patent completed.*

3321. R. A. Ronald. *Improvements in printing textile and felted fabrics, and in the machinery or apparatus to be used therein.* Dated December 11, 1862.

The patentee claims—1, The system or mode described of arranging and constructing the printing machinery with internal beaming roller, or any mere equivalent therefor, to admit of the felted or woven fabric being printed in pieces or continuous lengths, or in squares, by being wound on to and off these rollers as each printing operation of the exposed surface is completed. 2, The system or mode described of relieving the frictional contact of the cloth with the printing drum by means of rollers inserted beneath the cloth, or between it and the drum, so as to admit of heavy fabrics being printed in pieces, or lengths or in squares; also the mode described of keeping the edges of the cloth clear of the tenter hooks by means of cords carried round the printing drum. 3, The printing of felted or woven fabrics suitable for carpeting, druggets, crumb cloths, rugs, flannels, baizes, or other generally similar fabrics, in the manner and by the means described. *Patent completed.*

3322. R. Clark. *Improvements in machinery or apparatus for boring, winding, and lifting for mining purposes.* Dated December 11, 1862.

This invention relates to certain mechanical arrangements for effecting the several operations of boring, winding, and lifting, as connected with mining operations, in a more expeditious, effective, and economical manner than has heretofore been accomplished. Under one preferable modification, the machinery or apparatus consists of an open rectangular framing, built low to ensure stability. This framing carries one or more horizontal steam cylinders, which actuate a first motion horizontal crank shaft set in bearings on the framing. This first motion shaft has fixed upon it a spur pinion, which gears with a large spur wheel on a second motion horizontal shaft, also carried in bearings upon the main stationary framing. The first motion shaft, in addition to the spur pinion, carries a lever arm or cam piece arranged to work upon a vertical connecting rod, which is connected to one end of the main boring lever. This main lever is set upon a fixed overhead centre, carried by the framing; and to the other end of it is jointed or suspended the boring bar, which thus receives an up-and-down boring motion. The pedestal or journal carrying this lever is adjustable laterally, so that the parts can be set clear away from the line of bore, whenever access is required for cleaning or other purposes. The vertical connecting rod is fitted with a collar or shoulder piece for the support of counter weights, to be added as may be necessary for counterpoising the weight of the boring bars and appurtenances. To the lower end of this connecting rod, there is also jointed a horizontal connecting rod, the opposite end of which is jointed or linked to a crank or lever arm, set on a horizontal shaft carried by the framing, and which shaft also carries another short lever with a nut for being worked by a screw spindle. By turning this screw spindle, the catch of the vertical connecting rod can be set in or out from the path of the operating cam or lever upon the first motion shaft; and thus the stroke of the boring apparatus can be regulated or adjusted with the greatest nicety, or can be entirely disengaged from the operating cam. The second motion shaft, also, has upon it two winding barrels for the ordinary winding purposes of the mine, and for raising and lowering the pumps and boring rods. Both these barrels are fitted with conical or other-shaped frictional clutches, for engagement and disengagement at pleasure. *Patent completed.*

3323. A. W. Burgess. *Improvements in the preparation of anchovies.* Dated December 11, 1862.

This invention relates to improvements on the subject matter of letters patent granted to Elizabeth Burgess Burgess, for "improvements in the preparation of anchovies," dated November 12, 1859, No. 2573, and consists in preparing anchovies with butter in such a manner as to eradicate all extraneous matter, to preserve and improve the flavour of the fish, and to impart to the butter the delicate flavour of the anchovy, without detriment to the fish itself. *Patent completed.*

3324. J. Imray. *Improvements in apparatus used for mixing and kneading.* Dated December 11, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3325. W. Goulding. *Improvements in ploughs.* Dated December 11, 1862.

For the purposes of this invention, the land side of the body of a plough, in place of being upright, or as nearly so as may be, in respect to the sole of a plough, is formed in such manner as to incline from the sole over towards the furrow side of the plough; and the beam, when it is fastened to the body, in place of being directly over the land edge of the sole, comes more over towards the furrow side edge of the sole of a plough, by which the plough will be in a better state of balance and equilibrium than heretofore. *Patent completed.*

3326. T. E. Vickers. *Improvements in the construction of ordnance.* Dated December 11, 1862.

The object of this invention is to cool the block of metal in such a manner as to cause that portion of its section which is nearest to the inside of the bore to contract first, the other portions of the sections being allowed to cool upon it in the order of their respective distances from the axis of the piece. *Patent completed.*

3327. G. Winiwartar. *Improvements in the construction of portable houses, walls, or partitions of buildings, strong-rooms, safes, refrigeratories, reservoirs, piers, and other structures; also applicable to the construction of casks and similar articles, boats, and ships.* Dated December 12, 1862.

This invention consists in constructing walls or surfaces of any description, or to be employed for any purpose, by placing metal tubes bound round with straw, or other similar material, and steeped in clay, mortar, or cement, one on top or by the side of the other, between grooved posts, girders, or other supports, in the grooves of which the ends of the tubes are confined, forming thus a strong air-tight surface, which is a bad conductor of heat, and which has the advantage over ordinary wood, stone, or brick walls of being considerably stronger than these, whilst it has a much less bulk or thickness. *Patent abandoned.*

3328. H. Sanderson. *Improvements in the manufacture of table and other knives and forks.* Dated December 12, 1862.

This invention applies to the method of securing or fixing the bolster to the tang and blade. Hitherto the bolster has been usually made of one piece with the tang and blade by raising it by the hammer when hot, but, according to the present invention, it is a separate piece, and is joined to the blade by contraction after heating. The tang and bolster are made of the same metal, and the blade is fixed thereto in the following manner:—A hole being formed in the bolster of a suitable form and size for the insertion of the end of the blade, the bolster is to be expanded by being heated, and the end of the blade being placed in the hole of the bolster, the latter is allowed to cool, and consequently contract or shrink on to the blade, thereby making a firm joint, which cannot be loosened by any ordinary means. *Patent abandoned.*

3329. J. E. Roussel. *Improvements in hand and power looms for weaving.* (A communication.) Dated December 12, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3330. J. Gaskell and H. Walmsley. *Improvements in regulating the tension of yarn in the processes of warping, winding, sizing, weaving, and other similar purposes.* Dated December 12, 1862.

This invention consists in regulating the tension of the yarn by giving motion to the bobbins or other apparatus on which the yarn is wound. For this purpose the patentees put a loose or fast spindle into the bobbin or bobbins, and give motion to the said spindle or shaft by a wharve, wheels, or pulley, in connection with the moving power by a band or other suitable means, and thus obtain the required motion; or, if found desirable, the wharve or pulley may be turned on the bobbin head instead of being separate. Or they use a friction roller on which the bobbin or bobbins rest for the same purpose, this latter plan being more especially applicable to winding, sizing, and weaving processes. They place the shaft or bobbin in a vertical, horizontal, or diagonal position, as may be found most desirable. *Patent completed.*

3331. O. Hancock and S. W. Silver. *Certain compounds and substances applicable for electric insulation and other purposes.* Dated December 12, 1862.

In carrying out this invention, the patentees propose to combine caoutchouc with a milk or gum, the produce of a tree called Sapota Mulieri or bullet tree, which is found in British Guiana, and to which the term Ballata has been occasionally applied. This milk or gum possesses similar insulating properties to caoutchouc. They combine caoutchouc and ballata by mastication, rolling, or solution, according to one of the several processes well known among india-rubber and gutta-percha manufacturers. *Patent completed.*

3332. A. Mills. *Reefing and unreefing, furling and unfurling sails of ships and other vessels, and an improvement in the rotary yards and the journals in which the sockets or ends of the rotary yards work.* Dated December 12, 1862.

With reference to the reefing and unreefing, furling and unfurling of sails, this invention consists in making holes in the sails, which are worked on rotary yards or rollers; there is a hoop fitted on the rotary yard or roller, in which hoop is fixed a hook, which, as the yard revolves, catches a pall or shackle fitted on a hoop on the other or fixed yard. As the yard revolves, the hook before mentioned leaves the shackle and goes through the holes in the sail, which are disposed at such distances as that the hook will go through one hole at each revolution of the yard, until the sail is completely reefed, furled, or stowed. In unreefing or unfurling, a line attached to the end of the pall raises the pall from the hook until the sail is set, then, by slacking the line, the pall attaches to the hook again. As to the journals in which the sockets or ends of the rotary yards work, this invention consists in an application to the journals of an iron stay or stays by which the strength and bearing power of both yards is materially increased; the panel or sliding piece is improved by the addition on the aft side of it of a down-haul; the rotary yard or roller is strengthened by a cross iron let into it all through, the yard being divided into two or four pieces for the purpose of receiving the iron. *Patent abandoned.*

3333. G. Clark. *Improvements in fortification for the defence of ships, batteries, and forts.* Dated December 12, 1862.

The first part of this invention comprises a system of defensive armour composed of a combination of plates or sheets of iron or other metal with plates or sheets of tough material of less specific gravity than iron, alternating with each other, and closely compressed and fastened together side by side, forming a compact body calculated to resist the penetrating force of projectiles by exposing to it either the edges or the flat surface of a mass of combined plates. The second part of this invention refers to through-bolts, and is for the purpose of counteracting the tendency of a conical bolt-head when struck by a projectile to act as a wedge and spilt the armour plate. The inventor effects this object by means of a tubular sheath with a conical bore placed under the hole in the armour plate, through which sheath the bolt passes and rests upon the shoulder formed by the conical bore of the sheath, diminishing from the outside, the bolt being tapered to fit in the conical bore of the sheath. *Patent abandoned.*

3334. S. Fox. *Improvements in retorts and apparatus employed for the manufacture of gas, and also in purifying gas.* Dated December 12, 1862.

We cannot here give space to the details of this invention. *Patent completed.*

3335. J. Brown. *Improvements in the manufacture of armour plates.* Dated December 13, 1862.

The object of this invention is to give a curved edge to armour plates with the same facility as a straight edge is now given. Upon the bed of an ordinary planing machine a series of brackets are bolted at intervals; these brackets are to hold a stout bar of iron or steel, and are furnished

in their jaws with set screws, by means of which the bar can be forced to assume any curve required. When the bar has been bent by the pressure of the screws into the desired curve, the upper edge of the bar is made to serve as a guide to force the tool-box of the planing machine either to the right or to the left, gradually, as the table moves, and the plate on the machine has its edge pared or cut down exactly in conformity with the curve given to the guide-bar. The amount of curvature in the guide-bar determines and governs the lateral travel of the tool-box. *Patent abandoned.*

3336. J. W. BAKER. *Improvements in machinery or apparatus for spinning cotton and other fibrous materials.* Dated December 13, 1862.

This invention relates to hand and self-acting mules, and consists in giving a positive motion to the tin roller which drives the spindle by means of toothed gearing. The rim shaft of the mule is connected by toothed gearing or otherwise to an elongated toothed spur wheel of rather greater length than the draw of the carriage, so that as the carriage moves backwards and forwards a spur wheel in the carriage remains constantly in gear with the said elongated toothed spur wheel. The spur wheel in the carriage is connected by suitable gear to the tin roller shaft, and thereby drives the spindle by positive gearing, instead of the present mode of driving by hand. *Patent completed.*

3337. J. BROWN. *Improvements in hydraulic machinery.* Dated December 13, 1862.

This invention consists of a box containing a piston for the prevention of accidents in hydraulic machinery in the event of the main pressure-pipe breaking or engine stopping. This box the patentee places above the relief valve now in use, connecting the said box by means of a pipe to the lifting cylinder or cylinders. In the event of the main pressure-pipe breaking, or engine stopping, as aforesaid, the pressure contained in the lifting cylinder or cylinders will at once act on the piston and cause the rod thereof to press upon the relief valve, thereby preventing the water escaping from the lifting cylinder or cylinders, and thus stop the running down of any weight the machinery may be lifting. The box and piston may be fixed at any convenient place instead of above the relief valve now in use, but in such cases he fixes to the piston rod a mitre stop valve or clack, which will act on the seat of the piston box and have the effect as above described; or he connects the said piston rod with the existing relief valve. *Patent completed.*

3338. E. THOROLD. *Improvements in drill braces, which improvements are also applicable to spanners.* Dated December 13, 1862.

This invention consists in substituting for the usual ratchet-wheel and pawl used in ordinary hand drilling machines (commonly termed ratchet-braces) a cylindrical wheel or barrel forming or being the body or part of the body of the drill brace, the circumference of which may be of any desired form—viz., either plain, convex, or concave, or may present a succession of flat, convex, concave, or other suitably formed surfaces, the form of the end of handle varying accordingly. The handle or lever of the drill brace is held in such a position by any suitable and convenient means by a guide or guides, so that when moved to and fro in the usual manner the short end of the handle or lever comes in contact with the wheel barrel or body of the drill brace, and may be pressed so hard thereon as to enable the user to communicate the usual rotary motion to the drill brace, but thus doing away with the usual ratchet of ordinary ratchet braces. *Patent completed.*

3339. C. CORBET. *Improvements in rails for railways, and in the mode of forming the joints of the same.* Dated December 13, 1862.

This invention relates to a new form of rail and combined chair and fish to be used therewith for forming the junction of the rails, and consists in the use of a bridge-rail made wider at its upper part or head than at the lower part above the base, the sides being curved inwards at such parts, and then curving outwards to form the base. Into the hollow of this peculiar rail there is fitted accurately a correspondingly shaped chair, or chair and fish combined, which enters some little distance into such end of the rail, the peculiar shape of which prevents all chance of lateral or vertical motion at the joint. It is further proposed to form the chair, or chair and fish, with a base plate having raised ribs at each side, for the purpose of preventing any expansion of the base of the rail, the edges of the flanges of which abut against the raised ribs above mentioned. When used between the sleepers the rail is bolted down upon the base plate of the fish, or chair and fish, by special bolts with washers; but when used upon a sleeper, the two bolts and washers, which fasten down the chair, or chair and fish, to the sleeper only need be employed. In all cases bolts are used, the nuts or heads of which project partly over the flange of the rail, and so effectually prevent all tendency to rise from the chair, or chair and fish. That portion of the chair which acts as the internal fish may, if desired, be bolted into one rail, and merely slipped into the end of the other. Iron plates will be used under the rail on every sleeper, or on every second or third sleeper, as desired, in order to give bearing surface to the rail, and to prevent it from sinking into the timber. These plates will be made wider than the flange of the rail, and have holes in the centre to take a spike or bolt with a washer of peculiar shape made to take the flange of the rail and the head of the bolt. *Patent completed.*

3340. R. AITKEN. *Improvements in locomotive engines.* Dated December 13, 1862.

This invention relates to a peculiar system or mode of actuating the driving wheels of locomotive engines, with a view to the prevention of the great oscillation which occurs when using outside cylinders. According to this invention, it is proposed to transmit the power of both pistons to the centre of the driving axle, in place of to each driving wheel separately. For this purpose a hollow driving axle is used through which passes a straight driving shaft, having a single crank fitted thereon at each extremity outside the wheels. This driving shaft is coupled in any convenient manner with the hollow axle at a point central or nearly central with the length of the axle, and is supported near its extremities by a bush in the axle, or by collars forged or otherwise formed or fitted upon the driving shaft or on the interior of the hollow axle. *Patent abandoned.*

3341. J. PETRIE. *Improvements in machinery or apparatus for washing wool and other fibrous materials.* Dated December 13, 1862.

This invention relates to that construction of machine for washing for which letters patent were granted to John Petrie, jun., and Samuel Taylor, dated 11th January, 1853, No. 75, and consists in a method of driving the endless apron. For this purpose the inventor provides the said apron with a series of teeth or projections, in gear with which is a toothed roller, situate between the two end rollers, and these end rollers, therefore, he can use of a smaller diameter than would be necessary if they were the drivers. The above mentioned toothed roller may be in gear with the apron on the upper and lower sides thereof, or on one side only. *Patent abandoned.*

3342. J. J. THOMPSON. *Improvements in machinery or apparatus for making pies and for cutting meat for the same.* Dated December 13, 1862.

According to this invention, the inventor employs moulds of the desired shape of the pie, which moulds are placed in a press or similar apparatus. Into these moulds the paste is placed, and rams are then pressed into it to form the hollow crust. The rams are then removed, and the meat filled in, after which the top crust of the pie is applied, and another mould descending effects the required pressure to cause it to adhere, and to impart any pattern required. He proposes making the moulds and also the rams in two or more pieces, so as to part and thus admit of shapes being produced which would not otherwise leave them. The moulded pies are removed by the aforesaid parting of the moulds, or are thrust upward or downward. In cutting meat for pies he employs a series of revolving blades, the edges of which are situate within a grooved spindle; or he employs two series of revolving blades, the one extending within the spaces of the other. *Patent abandoned.*

3343. W. E. NEWTON. *An improved mode of and apparatus for repairing the rails, points, switches, and other parts of the permanent way of railways.* (A communication.) Dated December 12, 1862.

The object of this invention is to mend or repair the damaged portion of the rail, and render it serviceable without being obliged to resort to re-rolling, or re-manufacturing the whole rail. To this end the inventor cuts off or removes the surface of the damaged part of the rail, and he welds on to this part a flat piece of iron or steel of suitable width and thickness, the operation being performed in such a manner as to form a perfectly level surface from end to end of the rail. As the welding operation requires a high degree of heat, and as the web of the rail is thinner than the tread, the web is liable to be knocked out of shape during the welding process above-mentioned. To obviate this, he supports the rail during the welding process in a pair of moveable jaws, which will be made to clasp the web firmly and support the under side of the tread. These jaws may be worked either by a lever or by a screw like a vice. *Patent abandoned.*

3344. M. HENRY. *Improvements in fitting or applying propellers to ships and other vessels.* (A communication.) Dated December 13, 1862.

The object of this invention is to fit or apply propellers to ships and other vessels in such manner that the position of the propeller or direction of its axis with respect to the ship or vessel may be varied, so that the propeller may be turned or worked like a rudder, or its axis placed at various angles to the direction of the fore-and-aft line of the vessel. Another object of the invention is to fit propellers in such manner that they may be raised and lowered bodily, and thereby more or less submerged. By the arrangements herein described, a vessel may be brought round in a small circle, and perform other evolutions with ease and safety. *Patent completed.*

3345. M. J. ROBERTS. *Improvements in means and apparatus for preparing and spinning wool, cotton, and other fibrous substances.* Dated December 15, 1862.

This invention was described and illustrated at page 475 of the present volume of this journal. *Patent completed.*

3346. W. BESTWICK. *Improvements in braiding machines.* Dated December 15, 1862.

Instead of the revolving cams at the top of the machine, for giving tension to the yarns or threads, the inventor employs two or more horizontal combs connected to the rings of eccentrics, or to cranks, so that the combs may have an eccentric to-and-fro motion upon the yarns or threads, and maintain their tension effectually, without any danger of entanglement or breakage. These improved combs are to be applied to all sizes and descriptions of braiding machines. *Patent abandoned.*

3347. R. STANSFIELD and J. DODGEON. *Improvements in looms for weaving.* Dated December 15, 1862.

This invention consists—1, in an improved stopping motion for stopping the loom when the shuttle is not in the box. The inventors employ in each shuttle-box that description of swell which is acted upon by the top of the shuttle, but bring the end of the swell to the back of the box, so that, when the swell is held up by the shuttle, its end shall come in contact with a lever on the stop rod, and hold up the stop rod finger; but when the shuttle is not in the box, the end of the swell shall not be in contact with the lever, and thereby allow the stop rod finger to be depressed, and come in contact with the frog and stop the loom. They also employ the check strap for stopping the loom when the shuttle is not in the box. They connect the strap at two places in opposite positions to a boss or pulley working on a stud at the front of the slay, so that when the shuttle acts against the strap end in either shuttle-box, the boss shall be turned in the same direction. The boss is attached by part of the check strap or other connection to a lever on the stop rod, or to the stop rod finger itself, in such a manner that, when the shuttle is properly boxed and strikes the end of the check strap, it raises the stop rod finger out of contact with the frog; but, when the shuttle does not arrive in the box, the check strap is not pulled, and the finger not being raised comes in contact with the frog, and stops the loom. 2, in an improved arrangement of buffer or check strap. They coil one end of the strap round a concentric or eccentric boss fixed to the slay or lathe, instead of fixing to it the end of the strap itself, by which means there is greater elasticity and prevention of wear and tear than in any other method; and 3, in an improved mode of stopping the loom when the weft thread breaks, and when there is no weft. *Patent abandoned.*

3348. G. BUCHANAN. *Improvements in machinery used in crushing sugar canes.* Dated December 15, 1862.

In carrying out this invention, the patentee combines an oscillating steam engine with the crank or driving shaft on which the fly wheel is fixed, and with the crushing rollers, in such manner that the oscillating engine is placed between the fly wheel and the crushing rollers, and the fly wheel is caused to be beyond the end of the bed or base-plate, and it descends partly below the end of such plate. By thus combining the machinery, the position of the crank or driving shaft of the engine, and the framing which supports the same, are considerably reduced in height from the base or bed-plate, and the arrangement of the machinery is generally improved. For these purposes, the oscillating steam engine is placed between the fly wheel and the large cogged wheel, which is, by preference, furnished with internal teeth, but this is not essential. The crank or driving shaft turns in bearings on a suitable framing between the engine and the fly wheel, and the crank or driving shaft by a pinion thereon communicates motion to a cog wheel on a shaft which has fixed on it a pinion which takes into and drives the large cog wheel which gives motion to the crushing rollers as heretofore. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated March 21, 1863.

758. J. M. Hetherington, Manchester, machine maker. Improvements in machinery or apparatus for combing cotton and other fibrous materials.

Dated May 28, 1863.

1335. F. R. Piltz, Frederick-street, Hampstead-road. Improvements in the mode of producing ornamental surfaces, applicable to the general purposes of decoration.

Dated May 30, 1863.

1357. E. T. Hughes, 123, Chancery-lane. Improvements in apparatus for the transmission of motive power. (A communication.)

Dated June 4, 1863.

1395. M. V. L. De Wailly, Paris. An improved method of preserving carpets from the effect of dust.

Dated June 8, 1863.

1411. J. Hogg, jun., 49, Fleet-street. Improvements in the manufacture of show cards.

Dated June 11, 1863.

1454. C. L. V. Tenac, Tredegar, Monmouthshire, South Wales, civil engineer. An improvement in railway wooden sleepers. (A communication.)

Dated June 13, 1863.

1484. A. Méhu, Petit Talard, near the town of Saint Malo, France, mechanical smith. An improved helm for working the rudders of ships or vessels.

Dated June 15, 1863.

1492. J. Forrester, Burslem, Stafford. Improvements in the manufacture of bricks, quarries, slabs, tiles, earthenware pipes, and other earthenware or ceramic articles.

Dated June 16, 1863.

1502. F. S. Williams, Boston, United States. An improved apparatus for shaping plastic materials and hot but not melted metals by means of pressure, percussion, or rolling. (A communication.)

1508. J. Steele and W. Mason, Leeds, corn factor. Improvements in apparatus for removing the bran or outer skin from wheat and other grain.

Dated June 17, 1863.

1518. W. Crofts, New Lenton, near Nottingham, manufacturer. Improvements in the production of fabrics by lace machinery, and in means or apparatus employed therein.

Dated June 18, 1863.

1526. W. S. Lowe, Disley, Chester, and J. Cheetham, Oldham. Improvements in self-acting mules for spinning cotton and other fibrous materials.

Dated June 19, 1863.

1534. S. Middleton, Newtown-cottage, Hants, near Newbury, mechanic. Improvements in the manufacture of iron or other metal shoes, and in the method of securing the same to the hoofs of horses and other animals without nails.

Dated June 20, 1863.

1548. P. Fassio, residing at No. 1, Rue des Orangers, Nismes, France. A new method of connecting several fire-places with one chimney.

1560. J. Booth, Halifax. Improvements in winding machines.

Dated June 24, 1863.

1590. T. Redwood, Summerfield Works, Lower Homerton. Improved apparatus for straining or for mixing and straining liquid and solid substances.

Dated June 25, 1863.

1600. T. Page, Adelphi-terrace. Improvements in horse shoes and in their fastenings.

1602. R. Mushet, Coleford, metallurgist. Improvements in the manufacture of iron and steel.

1604. H. G. Craig, Passage West, Cork, shipbuilder. Improvements in machinery for manufacturing or paring iron and other metal plates for shipbuilding or other purposes.

1606. A. Watson, King-street, city, engineer. An improved fastening.

Dated June 26, 1863.

1608. A. Tulpin, Manchester, engineer. Improvements in machinery for stretching and drying fabrics. (A communication.)

1610. G. Boccius, Henrietta-street, naturalist. An improved composition suitable for the manufacture of candles and other like articles, and of pomatum, and an improved wick for burning with such composition.

1612. J. Griffiths, Derby, manager of iron works. Improvements in machinery for puddling iron and steel.

Dated June 27, 1863.

1616. W. and J. Bradshaw, Blackburn. Improvements in looms for weaving.

1618. J. Chatterton, Highbury, engineer. Improvements in lining iron and other tubes and hollow vessels, and in manufacturing corrugated tubes of plastic materials.

Dated May 29, 1863.

1620. W. Andrews, 237, Gresham-house, Old Broad-street. Improvements in apparatus for insulating electric telegraph wires.

1622. L. E. Hicks, New York. An improvement in inkstands.

Dated June 30, 1863.

1624. L. F. A. B. Marulaz, Guéret Creuse, France, commissary-general, Officer of the Legion of Honour, and Knight of the Order of Leopold of Belgium. Improvements in the manufacture of combs.

1626. J. Simpson, Darlaston, bolt and iron hurdle and fencing manufacturer. Certain improvements in iron hurdles and fencing.

1628. A. K. Richards, Berners-street, Oxford-street. Improvements in ordnance and firearms, and in projectiles to be used therewith.

1630. A. Silvester, Clapham-road, photographer. Improvements in apparatus to be used in the exhibition of dramatic and other like performances.

Dated July 1, 1862.

1634. T. Alliston, 237, Euston-road, iron bedstead maker, and R. Swift, 2, Hardy-terrace, Hounslow, civil engineer. An improved mode of and apparatus for manufacturing metallic joints for bedsteads, and the application of such joints to certain parts of bedsteads.

1638. R. C. Clapham, Walker, Northumberland, analytical chemist. Improvements in the manufacture of hyposulphite of soda, sulphite of soda, and sulphite of lime.

1640. J. and J. S. Harvey, Hanover-square, Newcastle-on-Tyne, tobacco manufacturers. Improvements in machinery for cutting tobacco into cakes suitable for the press.

1642. H. Hutchinson, merchant, 26, Rue Notre Dame des Victoires, Paris. Improvements in boots and shoes.

1644. J. and J. Cole, jun., Coventry, pattern designers. Improvements in looms for weaving.

Dated July 2, 1863.

1650. F. Ransome, Ipswich. Improvements in coating or preserving iron ships or vessels, or iron used for other purposes.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated July 1, 1863.

1643. G. T. Bousfield, Loughborough-park, Brixton. A new and useful machine for preparing cotton wool, or other fibrous material. (A communication.)

Dated July 4, 1863.

1667. H. A. Bonneville, 24, Rue du Mont Thabor, Paris. An improved machine constructed on self-moving principles for obtaining motive power. (A communication.)

Dated July 4, 1863.

1668. H. A. Bonneville, 24, Rue du Mont Thabor, Paris. Improvements in the manufacture of telegraphic wires, and in the apparatus connected therewith. (A communication.)

Dated July 7, 1863.

1690. G. P. Reed, United States. Certain new and useful improvements in watches or timekeepers.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, July 14, 1863.

577. O. Murrell. Generating steam.
585. J. S. Wells. Manufacture of stockings.
587. T. E. Symonds. Steering ships.
589. R. Saunders. Metal sheathing.
590. G. F. Lyster. Mooring buoys.
601. J. Pollard. Warp-dressing. (A communication.)
602. C. M. Palmer and J. McIntyre. Applying and fastening metal sheathing.
603. J. F. Gits. Revivification of charcoal.
607. E. A. Wünsch. Treating seaweed.
615. W. Whittle. Manufacture of nails.
616. T., E., and R. Thornton. Preparing fibrous substances for spinning.
617. J. Clinton. Construction of flutes.
623. S. H. Foster and T. Bunney. Looped fabrics.
624. J. Miller. Horticultural buildings.
626. T. W. Osborne. Improvements in lamps.
632. W. H. Buckland. Producing gas for illuminating purposes.
635. A. W. Makinson. Locomotive and stationary engines.
642. T. G. Webb Manufacture of articles of pressed glass.
648. H. A. Bonneville. Removing stains. (A communication.)
649. J. Isherwood. Working presses.
652. W. Inglis. Steam boilers and engines.
662. R. A. Brooman. Voltaic belts and bandages.
672. J. Renshaw. Dressing, raising, and brushing silk and cotton velvets.
673. W. Rossetter. Beam warping machines.
676. L. Desens. Bath or bathing machine.
677. W. Clark. Breech-loading firearms. (A communication.)
681. J. Harris. Rolling armour plates.
687. J. H. Johnson. Fastenings. (A communication.)
694. J. Tangye. Hydraulic punching machines.
703. T. W. Willett. Reefing and furling square sails.
715. J. Cox. Swimming baths.
750. C. Pryse and D. Kirkwood. Breech-loading firearms.
797. J. Norton. Projectiles or ignition missiles.
801. J. Grantham. Manufacturing compressed fuel.
805. W. Clark. Winding or copping frames. (A communication.)
839. W. Clark. Preventing fermentation in alcoholic and other liquids. (A communication.)
845. W. H. Phillips. Cleaning the bottoms of ships or other floating vessels.
1291. A. W. Hofmann. Preparing colouring matters.
1324. M. Henry. Raising, forcing, and moving fluids. (A communication.)
1335. F. R. Piltz. Producing ornamental surfaces.
1339. C. E. Laederich. Watches.
1409. A. J. Hollingsworth. Improved spirit compass with screw lever.
1546. G. Haseltine. An improved oil. (A communication.)
1594. J. L. Hughes. Ornamenting porcelain.
1616. W. and J. Bradshaw. Looms.
1622. H. Hutchinson. Boots and shoes.
1643. G. T. Bousfield. Preparing materials. (A communication.)

LIST OF SEALED PATENTS.

Sealed July 10, 1863.

106. C. H. Townsend and J. Young.
107. R. A. Brooman.
118. J. Butler.
129. E. Howes.
130. T. C. Barraclough.
132. J. Harrop.
134. R. Ferrier.
140. A. Prince.
141. W. E. Newton.
152. I. Ashe.
202. N. Wood.
259. E. G. Muntz.
292. F. G. Grice.
391. J. Grantham.
682. C. T. & A. Lutwyche.
741. G. H. Smith.
1090. E. Mitchell.

Sealed July 14, 1863.

131. T. C. Barraclough.
133. G. Graham and J. McLeod.
137. J. P. Bath.
139. J. W. Child.
143. R. A. Brooman.
150. J. Edwards.
157. E. Sabel.
164. J. J. Lundy.
185. W. Clark.
187. E. Bazin.
189. Sir C. Lindsay.
230. A. L. Liétout.
314. G. T. Bousfield.
321. J. A. Manning.
408. W. Clark.
437. D. Tassin.
457. W. Trustrum.
467. W. Clark.
468. W. Clark.
485. W. H. Gauntlett.
514. W. Clark.
598. D. B. Parsons.
644. W. E. Newton.
906. S. A. Couperie.
1007. J. W. Proffitt and W. L. Duncan.
1047. H. E. Carchon and E. F. Raybaud.
1099. J. Badart.
1159. G. T. Bousfield.
1218. G. T. Bousfield.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

1644. R. Pollit.
1673. G. Davies.
1683. F. Ayckbourn.
1685. F. Mordan.
1695. C. G. Hill.
1696. W. and W. Allen.
1709. A. V. Newton.
1751. W. Barrett.
1795. W. E. Taylor.
1834. G. C. Ange.
1871. W. E. Newton.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

1590. A. L. S. and E. C. A. Chenot.
1616. W. B. Adams.
1635. J. Fowler and W. Worby.
1720. R. Richardson and J. E. Billups.
1766. E., T., A., and W. Lord.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SPECIFICATIONS PUBLISHED

For the Week ending July 11, 1863.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JULY 24, 1863.

COMMUNICATION BETWEEN PASSENGERS AND GUARDS.

It is quite impossible to find a parallel for the position in which the traveller places himself on an English railway. Not only is he exposed to dangers and risks of a very peculiar kind, but he has in addition to submit unresistingly to them, without the power of making his condition known. The sufferer has not even the poor consolation of saying with truth, that he did all in his power to avoid evils which result in broken bones, ruined constitutions, or melancholy bereavements. The mere fact of entering a carriage, under existing arrangements, deprives the traveller of all that liberty which he prizes so much. Locked up in a compartment, he surrenders himself body and soul, into the hands of those who act for him; think for him; nominally take care of him, and deliver him—if all goes well—at his destination in good preservation, as they would a bale of goods, an ox, or a horse. The railway passenger has no identity, no individuality, and certainly no power, while the train is in motion; at a station, the matter is slightly different, very slightly; and even though each passenger there ruled as an autocrat, once the whistle sounds, and the open country is entered, that power is gone, and strong or weak, old or young, he is left depending wholly on his own resources, without the means of obtaining aid even in a death struggle. As a consequence, we find crimes committed; episodes enacted in the compartments of railway carriages, which, converting them into the semblance of slaughter-houses, make thousands who are daily exposed to the lik tremble with that worst of all terrors, a nameless dread. Such things are rare; had it been otherwise, precautions, effectual enough, would have been taken against their recurrence long since; but they are none the less fearful or deplorable for their rarity, nor does the fact exonerate those in authority from the responibility of permitting a state of affairs to exist, which gives ample scope to the lunatic, or the criminal, for the commission of deeds the very mention of which is heard with a shudder.

On Thursday last, a compartment in a second-class carriage of the Liverpool express to Euston, was the scene of a fearful struggle: strong men fought to take and preserve life, as men only fight with such objects in view. Michael Lyons, a traveller to all appearance, highly respectable, furiously attacked two of his fellow-passengers with a knife, when near Bletchly. The train being express did not stop for fifty or sixty minutes afterwards, until which time, of course, those attacked could receive no aid. Fortunately, they were both strong men; and the lunatic—for such we presume him to be—was overcome after a contest which converted the carriage into a shambles. Had it been otherwise, had those attacked been weak women or helpless invalids, the result would, of course, have been far more disastrous. That the matter fortunately terminated as it did, is not due to any precautions taken by railway officials, but simply to what is called, (properly or improperly,) chance—to a species of hap-hazard, in fact, which should have no existence in railway routine.

Now, were such an occurrence unique, we might have passed it over in silence; were it impossible to prevent its recurrence, to that silence we would have added regret; but as it is neither without a parallel, nor unavoidable in future, we assert that such an assault is to the last degree disgraceful to railway management. On no other railways but those of Great Britain do we find men treated as irrational beings, confined for hours together without the power of communicating their wants or their wishes to those who can aid or assist. Events daily place in a more prominent light the absolute necessity for an efficient means of communication between passengers and railway guards. Such an episode as that we have detailed is no slight matter to be passed over in silence. It is suggestive in the highest degree. It contains a warning which railway directors would do well to regard calmly, dispassionately, like reasonable men. It shows in a sufficiently fearful light one of the dangers resulting from that species of incarceration, to which they day by day needlessly condemn travellers—an isolation which is conducive to the most terrible results, and the longer continuance of which is not only unnecessary but criminal. Let a free communication exist between guards and passengers. No complicated contrivance is necessary for the attainment of such a result. If existing arrangements preclude the adoption of a means by which the guard can pass from end to end of the train he has in charge, there is at least nothing to prevent the adaptation of other and scarcely less useful means to the same end. A signa cord, accessible to all the passengers, is universally employed on every railway in America; and on very many Continental lines as well. The abuse of the privilege thus conferred is quite unknown. Are our railway travellers less steady and sensible than foreigners? The idea that it would be used by foolish boys for a "lark," or by timid women from the fear of imaginary dangers, is absurd.

Railway companies have hitherto treated the matter with a magnificent apathy; they have neither raised their voices for nor against the novelty; they simply have done nothing. On a few lines the guard and engine-driver are placed *en rapport*, it is true; but passengers are still treated as "goods" all over the kingdom. It is high time that such contemptuous sloth was shaken off. Such an occurrence as that of Thursday last is a terrible stimulus to exertion, which we trust will not need repetition.

LIGHT STEAM BOILERS.

The actual quantity of boiling water, required for the safe development of a given amount of steam power in a certain time, is a question which has never yet been decided, and most probably never will. So long as the heated plates, of a flue or a fire-box, are in contact with a depth of fluid sufficient to absorb all the heat imparted to them, it seems likely enough that every necessary purpose is fulfilled; but what the exact quantity required for the attainment of this object is, must remain for the present, at least, a doubtful point, depending not only on the description of plates employed, and the quality of the water used, but on the the intensity of the draft, the quality of the fuel, and many other points of detail, too various and uncertain to permit a very close approach to theoretical limits in practice. The ambiguity of the question, or its answer, does not, however, lessen their importance. The largest field for the employment of steam power is found in our naval and mercantile marine, and there at least, does the question of the reduction of every portion of the machinery, to the smallest possible limit of weight, assume the greatest importance; and very little reflection is required to convince us that that form of steam generator is most suitable for marine purposes, which will work safely and economically with the least possible quantity of water.

Whatever improvements may have taken place in our marine engines, it is certain that they have been few enough in the marine boiler. Since the introduction of tube flues, little or no alteration has taken place in the general principles of its construction, or in those matters of detail on which its suitability to its position depends. It still exists in all the clumsy majesty of size, much as it did half a century ago. Alterations in its internal arrangements have been few; in its external form still fewer; and for the sake of securing some important advantages, our engineers have been content to sacrifice many things equally valuable. As a result, we still find our ships encumbered with huge structures of plate iron, costly to make, difficult to repair, and of the very worst possible form for fulfilling one at least, of the legitimate purposes of a steam generator, that of sustaining a heavy pressure exerted within it. When anything above a nominal pressure is required, the engineer is compelled to resort to the use of stays to such an extent, that the interior of the boiler is rendered almost inaccessible for repairs or examination, while its weight and cost are seriously increased. Nor are these the least evils induced by its defective form. From the peculiar arrangement of up-takes and ashpits, stokeholes are, as a rule, almost unfit for the existence of human beings within them, the last refinements of ventilation being necessary to render them endurable when situated at the bottom of a large vessel; man-of-war or merchantman. The worst defect of all is found in the fact, that these boilers carry tons of water, to accomplish results attained as easily in other situations, by cwt. weights of the liquid.

It is pretty certain that a given area of heating surface will produce nearly similar quantities of steam, by the combustion of equal weights of fuel, whether it is covered with water to the depth of an inch or a foot; whether the boiler, in fact, contains a gallon, or a hogshead; a cwt., or 10 tons. Certain rules are, it is true, laid down by James Watt and others, for determining the proper area of evaporating surface, &c., which a well-proportioned boiler should possess. Such rules are, however, simply absurd in a general sense; the heating surface with which the water is in actual contact being, of course, the most important measure of boiler horse-power. The cubic contents of the space filled with fluid, that occupied by steam, and the water surface exposed, are merely matters of detail, which can only affect the quality of the steam supplied to the engines, and have little or nothing to do with its quantity; save in one respect, which is simply, that the reduction of the quantity of water contained in a boiler, is always accompanied by an increase in the economical production of steam, from the very obvious reason that the agitation of many tons of any liquid by the process of ebullition, must waste power to a very considerable extent; consequently, any reduction in its quantity is attended by a proportionate diminution of this waste. Most engineers are well aware of this fact. Thus, Mr. Armstrong states, in his valuable work on steam boilers, that he has found considerable advantage accrue from the introduction of hard-baked bricks, within the water space in large waggon and cylindrical boilers.

There are, however, other considerations besides questions of economy or convenience, which must regulate the amount of water-space

allowed in a generator. We usually find that the extent and form of the heating surface is its real measure, far more than anything else. And these, again depend on shipboard, in a great degree on external agencies, which have nothing whatever to do with engine or boiler, except so far as they govern their shape and size. The weight of a boiler does not, however, depend on the greater or lesser extent of water-space which it affords, but on the heating surface—in well-constructed boilers at least whose external superficies bear a very small proportion to the surface exposed to the direct action of the heat in the fire-box or flues. No matter what form that surface may assume, the metal of which it is composed should form a large proportion of that employed in the construction of the boiler, and must influence its weight more than any other consideration. We thus meet with generators, every now and then, which develop as much useful effect with a few gallons of water as ordinary boilers do with tons. But these generators are never light in an equal proportion; and the ardent pursuit after a boiler, light in this sense, is really a mere waste of talent, time, and money. We are, however, speaking just now more particularly of the marine boiler; and although we do not believe that its weight, when empty, can be materially reduced by any change in form or construction, we nevertheless feel certain that its weight—when taken as a whole, with its contained water, as a distinct apparatus for the production of power—is excessive, and that its reduction to reasonable limits should be one of the first objects of the engineer.

That this desirable end will ever be attained while we retain the use of flues returning over the fire-boxes, we very much doubt, because this arrangement of heating surface requires the employment of an immense quantity of water, not because it is in any way necessary to the effectual absorption of the heat produced in the furnaces; nor yet because dry steam cannot be supplied without it, but solely because large spaces are left within the boiler which cannot be so conveniently occupied by anything else. Thus, we find a distance of 8 in. or 12 in. at least, left between the crowns of the furnaces and the lowest rows of tubes, in order that a man may find access to the fire-boxes when they require repairs. 3 in. of water over a fire-box are ample under other arrangements; and we know that the excessive space now provided, easily accommodates many tons of dead weight, which is of no possible service. Few engineers who have gone into the subject in a proper spirit, will be disposed to assert that a boiler can be constructed on correct principles, which entails the necessity of carrying about, and heating, tons of water in no wise essential to the working of the propelling machinery; or that it can possess any compensating advantages which preclude the idea of its supersedal by generators of a different form. Its retention in service now, is we believe, in a great degree due to that conservatism on which we have dwelt sufficiently in a previous article, aided by the failure of novelties whose introduction we could not, under any circumstances regard as a step in the right direction.

We must remember that this question of marine boiler improvement daily presents itself to our notice in a more important light. However suitable the present normal form may be for pressures below 15 lb. or 20 lb., it signally fails when that pressure is exceeded. No amount of staying can possibly convert it then into a safe and economical generator. The growing tendency to employ high-pressure steam, the active competition in marine engine building, render its remodelling a question of the utmost importance—a question which should neither be slurred over, nor treated with haste and carelessness. We are heretics enough to believe that it would have been better for the marine engine at least, that a condenser had never been invented at the time it was. The possibility of attaining a paltry vacuum of 10 lb. or 12 lb. to the inch, has been the greatest bar to real progress the steam engine ever encountered. Had no such thing been attainable, we would long since have had propelling machinery as light and as simple at sea, as we have on our railways, where a vacuum was and is unattainable. At sea, that which should have been employed as a good servant has become a bad master, to whom space, money, and every other consideration are given up, in order to obtain results, the advantage of which are at best quite inadequate to the sacrifices made.

That the present form of marine boiler will be much longer retained, we doubt; that it will be replaced by something much better, we believe. Indeed, unless we wilfully shut our eyes to the light and experience afforded us by locomotive engineering, we can scarcely go astray. The boiler of the locomotive is, after all, the best which has ever been designed for the development of vast power within a limited space, and it requires but trifling modification to render it as suitable for the purposes of propulsion at sea as on land. The reduction of weight and space, the economy of fuel, the facility for carrying the highest pressures with ease and safety, which its use would secure, are advantages sufficiently important to outweigh all considerations of extra expense even if they existed. What we want on ship board is simplicity, not complication; and it is much better that we should avail ourselves of what is known and tried, rather than introduce novelties of which past experience tells us nothing.

THE ROYAL AGRICULTURAL SOCIETY.

THE MEETING AT WORCESTER.

(From our Special Correspondent.)

By the close of to-day, one of the most successful Great Meetings of the Royal Agricultural Society—the 25th in the series—will have come to an end. The 5,839 inanimate exhibits, covering a space 600 yards long by 200 wide, and representing a capital of thousands upon thousands of pounds; the 330 exhibitors with their numerous assistants; the multitude of visitors attracted by the Great Fair, will all be shortly dispersed to the four winds of heaven, and the good old city of Worcester will subside once more into its pristine provincial quietude. No doubt that all concerned—implements, exhibitors, and visitors—will have profited, each in their several ways, by the meeting. Many of the implements will reappear, in improved forms, at future shows; all the exhibitors will have gained in experience, the greater part in extended connection, and many perhaps, in pocket; while the agriculturists will have been enabled, by a practical and ocular examination, to choose the implements the best suited to their several special wants. Even to the casual visitor and pleasure seeker, the view of such an agrico-mechanical show may suggest lessons of interest and importance. Upon no slight foundation, the sight of such a collection of implements for supplying human wants, might raise up a theory of human progress, founded upon the advancing stages of man's dominion over labour. Between the savage with his stone hatchet, and the civilized man with his steam engine, there are several stages of progress; but each takes its stamp from the expedients adopted to lighten toil. The first step beyond savagery is evidently the subjugation of beasts of burden. Then comes the use by man of his fellow-men as slaves. The third and perhaps last stage is the employment of the inanimate forces of nature in the fulfilment of daily wants. These several stages are all commemorated in the history of our own little island, and each step can still be seen in progress in different parts of the world; while at such a collection as the one at Worcester, almost every mechanical operation connected with the preparation and supply of food may be seen—from a steam cultivator, capable of ploughing an acre an hour 12 in. deep, to a Yankee apple-paring machine.

In attempting to give an account of this great agrico-mechanical meeting, we feel the difficulty that is always met with when translating mechanical combinations into words. The real engineering language is graphic delineation; no "word-painting," however clear and eloquent, can convey mechanical ideas with the certainty and completeness to be obtained by the combination of a few lines. Next to seeing a machine itself, the next best thing is to see its delineation; and even a rough chalk sketch has often more significance than the most elaborate description. It would be impracticable for us to give illustrations of any of the exhibits at such a short notice; but, fortunately, however, we are able to refer to back numbers for illustrated descriptions of many of the articles exhibited; and we hope to describe more completely at a future period some of the more complicated and interesting objects—such as the ingeniously constructed dynamometers, employed by Mr. Amos, C.E., the Consulting Engineer of the Society, for testing the power consumed in working the various implements. An engine, a steam-plough, a horse-plough, a thrasher, a machine worked by hand power, each and severally requires a dynamometer of a different construction for testing the consumption of power; and these apparatus appeared to us to embody features of greater mechanical interest than perhaps any other machines on the gronnd.

The Exhibits.

Clayton, Shuttleworth, and Co., of Lincoln, exhibited a 12-horse, two 8-horse, a 7-horse, a 6-horse, and a 4-horse power portable engine, and a 10-horse and an 8-horse power stationary engine. They also shewed a 5-horse power portable engine, combined with one of Appold's centrifugal pumps, and a 10-horse power double cylinder traction engine, specially intended for dragging thrashing machines from farm to farm. Its chief novelty consisted in the use of a self-acting compensating motion for keeping both wheels in gear when turning curves. The complete utility of, or rather necessity for, this arrangement, appears to us to be rather questionable. All these exhibits are of the excellent Stamp-End pattern. This firm also sends one of their treble-blast finishing thrashers; an independent fixed finishing thrasher; a combined portable double-blast finishing machine; a combined single machine; a combined double machine; and 2 straw elevators—one on Hayes' plan, and the other on Campain's. Two grinding mills and a couple of circular saw-benches, complete the list of things at the Stamp-End stand.

Aveling and Porter, of Rochester, sent three of Mr. Aveling's traction engines, the use of which appears to be extending. We fully described these engines in our number for February 27th. Several of the other makers pay a

royalty for the partial or entire use of Mr. Aveling's patented plan of traction engine; amongst whom we may mention Messrs. Garrett of Leiston, and Brown and Mays of Devizes—the latter of whom, however, have placed their engine boiler on springs and a locomotive side-framing. The engine is of 8-horse power, with a cylinder of 9 in. in diameter, and the tender, at the back of the fire-box, can contain sufficient water for a six-miles' run, and coals for fifteen to twenty miles. From its being built with a pitch chain on each side for the two speeds, the engine does not present the simple appearance of Aveling's traction engine, and it is also too close down to the ground—which would lead to difficulties in soft soil.

James Haywood, jun., of Derby, exhibited a 10-horse power fixed engine and an 8-horse power portable, both of which were tested, and their performances appear further down. These two engines were furnished with a peculiar governor, which—as it procured the great advantage of a variable expansion—deserves further notice. An expansion valve was used, worked by an extra eccentric loose on the shaft. The governor itself was of the gyroscopic kind, mainly consisting of a heavy ring revolving at an inclined plane to the axis of the shaft. Any variation in the speed caused a proportionate change in the inclination, and these alterations were communicated to the loose eccentric on the shaft by an arrangement of bevel gearing similar to the one adopted in Siemens' governor. A French portable engine in the International Exhibition—that of Albaret—also employed a gyroscopic governor and the arrangement seems worthy of notice by those interested in introducing in a simple form the invaluable principle of variable expansion.. It appeared to us that this gyroscopic governor might be combined with Dubbs' arrangement of using one eccentric for reversing the valve gear of locomotives. The "wobbling" appearance of the gyroscopic apparatus is rather a drawback, but this might be corrected to a great extent. The firm also exhibited some thrashing machines, a variety of chaff-cutters, and we noticed some very neat cast-iron garden chairs at this stand.

Messrs. Clinton and Owens (late B. Fowler and Co.) exhibited no less than 80 different articles of their manufacture. We noticed a very neat arrangement of combined steam-engine and pumps, consisting of a 6-horse power horizontal engine, 8 in. cylinder, 12 in. stroke, working a set of treble 4 in. plunger pumps, the whole on one strong bed-plate. It was intended for supplying a nobleman's country house with water. We also noticed at this stand a useful shape of double-action force-pump, for breweries, &c., with a central and easily accessible position of valve chamber. Mr. C. Fynes Clinton, the senior partner in this firm, was formerly one of the favourite pupils of Mr. William Fairbairn, of Manchester.

Marshall, Sons, and Co., of Gainsborough, sent a 10-horse, an 8-horse double cylinder, and a 2½-horse power portable engine, very much after the Stamp-End pattern. They also exhibited some thrashing machines and saw-benches of very good wormanship.

J. B. Brown and Co., Cannon-street, made an appearance with a great variety of articles, amongst which we noticed a number of Shanks' neat lawn-mowers, and one of the compact little engines with an upright boiler made by this firm, and also exhibited last year at the Battersea show.

Messrs. Burgess and Key exhibited several of the very complete reapers of Mr. McCormick, of Chicago—that most fortunate of all patentees. They also sent a variety of chaff-cutters and churns, and a couple of their excellent mowers.

Mr. Henry Mulliner, of Leamington, exhibited a patent wheel, made in the same manner as the wheels of some of the American carriages shown in the American Court of the late International Exhibition. The entire round of the wheel was formed of only two pieces of wood, bent by machinery to the required shape; instead of the usual plan of using one felloe to each couple of spokes. We do not see that this achievement could be properly carried out with any other wood than the wonderfully tough American hickory.

Another local exhibitor was Mr. Gilbert, of Evesham, who sent a portable engine with an oscillating cylinder; a peculiarity of construction which we should think to be very uncalled for in an engine of this class.

Mr. Stephen Holman showed a variety of hydraulic apparatus, amongst which we noticed a very useful tool for engineers; a neat hydraulic punching bear by Tangye and Co., for punching ¾ in. holes through ½ in. plate.

Bury and Pollard worked one of their neat double-acting pumps by means of an extremely ingenious self-regulating windmill, invented by W. H. Zahn, of New York. We remember that this wind engine was also exhibited in the American Court of the International Exhibition. The peculiarity of the apparatus consists in the eight sails being self-regulating, and they can thus work day and night without attention. The sails are caused to present more surface to the wind, in proportion to the force of the wind acting on self-adjustable springs attached to each sail.

The "new implements" exhibited at the stand of the real steam cultivation pioneer—Mr. John Fowler—were a five-tined cultivator and subsoiler; a harrow and cultivator, and also a drill, for working alongside of the cultivator.

It is to be regretted that the traction engines were not submitted to any competitive test. Robey and Co. exhibited a 12-horse 8 in. double cylinder traction engine. The hind pair of wheels are 6 ft. in diameter with a 12 in. face, and the steering wheels are 4 ft. 6 in. in diameter, and 10 in. broad. Two chains are used for a purpose that might be fulfilled with one; and both are of the same size, although one has to go through three times as much work as the other. The driving wheels appear too light, and show symptoms of the spokes working loose in the tyre. Allchin and Son, of Northampton, exhibited a very well arranged traction engine. It is of 10-horse power, with a steel boiler, fed with a pump and a Giffard's injector. The working parts are all of steel; and the cylinder, 8½ in. in diameter, is placed in the smoke-box. The driving wheels are 6 ft. in diameter, and 13½ in. wide; and the whole is mounted on india-rubber springs. The wheels appear too light, and were cracked in some places. The chain of Lee and Co.'s traction engine is a rather rough job, and the wheels have too small a surface for soft ground. Garrett's traction engine, on Aveling's plan, is a good strong job. The general use at present of springs to the "traction engines," is a feature of improvement that will evidently conduce to their durability.

As we stated last week, there is no implement of any marked novelty in the show, except, perhaps, the chaff-cutter we then noticed. Burrell, of Thetford, was absent from the Royal Agricultural Show—as indeed he has been for several years. Ransomes and Sims were completely unrepresented; and Garrett, of Leiston, only sent a traction engine. The mere recapitulation of the names of Hornsby and Sons, Tuxford and Sons, Barrett, Exall, and Andrews, Samuelson and Co., Amies and Barford, Holmes and Sons, Wallis, Haslam, and Steevens, &c., will sufficiently recal the character of their stands.

THE TRIALS.

Steam-engines Fixed and Portable.—The total amount of the prizes offered for this class of fixed and portable steam-engines, was £100—viz., £40 for the class of fixed steam-engines not exceeding 12-horse power; £10 for the boilers of such engines; £25 for the class of portable steam-engines above 8-horse power; and £25 for similar engines not exceeding 8-horse power. These prizes seem to have been divided, with a view of pleasing all parties; as in certain schools, where all the little boys who have not been outrageously bad, get some prize or other at the end of the year. However, we have no doubt that the judges can give excellent reasons for what they have done.

The fixed and portable steam-engines were tested under an oblong wooden shed erected in one corner of the trial-yard. About one-half of the longitudinal space was devoted to fixed engines, the other to portables. The "force-resisters," as they are termed in the society's prize-sheet—improved forms of De Prony's well-known friction brake—could be adjusted as required on a wooden tramway laid down inside the shed. Three of these dynamometers were used. They were constructed by Messrs. Easton and Amos, who, amongst other improvements, have dispensed with De Prony's long lever, thus increasing the accuracy and steadiness of the apparatus. A boiler on wheels, furnished by the society, was employed to test the stationary engines, and, placed on a wooden platform parallel to the tram under the shed for the dynamometers, it could be adjusted to any position in which the stationary engine under trial happened to be fixed. The steam was fed into the fixed engines through a piece of flexible piping. The engines, fixed and portable, were thus placed in the intermediate space between the two tramways, and straps furnished by each exhibitor communicated the power from the engines to the breaks. The portable engines were necessarily tested with greater facility, and could be at once brought in and off by a team of horses.

It may be mentioned that all the steam-gauges in the engines intended to work the machinery in motion, were previously tested by Mr. Amos. Some were found to vary as much as 6 lb. above the stipulated pressure of 45 lb. on the square inch, and others to the same amount below that pressure, when compared with the standard gauges in the possession of the society.

It seems to be generally supposed that the prizes for engines are adjudicated with reference merely to consumption of fuel. The judges stated, however, in the "prize-sheet," that regard will be had "to the price, simplicity of construction, probable durability of the whole and in detail, and the means provided for easy access to the working parts, and to economy of fuel." It is required that no fixed engine should exceed 10-horse nominal power, nor have a diameter of cylinder larger than 11½ in. "One of the portable engines must not be more than 8-horse nominal power, nor must the diameter of the cylinder be more than 9½ in." It is also required that the engine be taken to pieces, either before or after the trials, that the piston, slide, and valves, be open to examination by the judges. A smaller diameter of the tubes than 2¼ in. inside is not allowed; nor must

they be less than No. 12 wire gauge thick, nor have a smaller breadth of plate between them than 1 in. This year, the R. A. Society has permitted a pressure of 50 lb. on the square inch, being an increase of 5 lb. on the pressure allowed at the last steam-engine trials, at Chester, in July, 1858. As at all the former trials, Welsh Llangennych coal was used.

The portable engine being brought on to the ground, 7 lb. of coal and 1 lb. of wood per each horse power are carefully weighed and served out to the attendants, the number of whom, by the bye, is not determined by the regulations. The fire is then lighted and the fire-box fired, until the steam is got up to a pressure of 50 lb. on the square inch. The instant that this pressure is attained, all the coal out of the fire-box is taken away and weighed, and this weight deducted from the quantity first given, in order to afterwards ascertain the amount of coal consumed in raising the steam. The engine is then set to work and allowed to run against the weight on the dynamometers, until it is unable to keep up the required speed of the brake. A counter, adjusted to the brake, registered the number of revolutions.

The moment the engine stops, another portion of fuel is served out, consisting of 14 lb. of coal—no wood—and the steam is again got up to the pressure. of 50 lb. per square inch. At Chester, 1 lb. of wood per horse power was allowed for the second experiment. The engine is then started and allowed to run until the fuel is so far consumed that the engine can no longer keep up the required number of revolutions of the brake. Every means are used by the exhibitors to urge the expiring force of the engine, and the fire is always burnt so low that but a slight layer of ashes are visible in the grate. The fire-bars are purposely made very close together, and the coal is from the beginning broken up by a hammer into small pieces, about as big as a hazel nut. It is evident that the slightest accidental variation in the quality of even a small portion of the fuel would materially effect the result. When the engine can no longer keep the brake at the declared speed, it is stopped, and the total number of revolutions of the brake effected by the second bout, and recorded by the counter, are noted down.

The speed of the brake is of course got by multiplying the declared number of revolutions per minute of the engine by the radius of the driving pulley, and dividing the product by the radius of the brake pulley; the weight on the brake, or the load on the engine, is determined by the nominal power of the engine multiplied by 33,000, and divided by the circumference of centre of effect of the brake collar multiplied by the number of revolutions of the brake per minute; while the duty of engine, or the *mechanical time*, of either of the two experiments, is obtained by dividing the total number of revolutions recorded by the counter during the bout by the indicated number of revolutions of the engine per minute.

It would evidently give a very unsatisfactory result if only the coal consumed in the second run were taken into account; and "racing" engines, ingeniously furnished with firebricks in the fire-box, or by the adoption of other means, might, while getting up steam, acquire such a store of caloric as to distance other engines unprovided with such appurtenances. The fuel, however, consumed in getting up steam, is taken into account in the following manner:—In the same ratio that the number of revolutions recorded by the counter at the end of the second bout bear to the quantity of coal then consumed, so are the number of revolutions of the counter at the end of the first experiment to the quantity of coal not consumed in getting up steam. This amount being thus ascertained, it is deducted from the quantity used in the fire-box during the first experiment, and the difference represents the quantity consumed in getting up steam.

The following are the awards of the judges, as published on Monday last. The prizes are apparently given to the engines effecting the highest duty; as the relative merit in design, simplicity of construction, accessibility, &c., are very far from being equal in the different engines tested. The £10 prize for a 12-horse and under fixed steam-boiler was not competed for. The judges for these trials were D. K. Clark, Esq., C.E., late Superintendent of Machinery in the International Exhibition, and the author of the well-known work on Railway Machinery; G. V. Gooch, Esq., C.E.; Mr. Stewart, Midland Railway; assisted by Mr. James Easton, jun.

clothed fireboxes, variable expansions, &c. The result could not be doubtful—it would be like a race between a gentleman's thoroughbred and a farmer's cart-horse—and two engines from the same shop would have given widely-different results. The makers absolutely rejected the proposal, and refused to get up the steam. It will evidently be best for all parties for the society to adhere to its determination to ignore racing engines. Farmers and others do not want "racers," but rather useful cart-horses, and there are many simple means of diminishing the consumption of fuel without having recourse to such *tours de force* as were carried out in the exhibits that figure at the head of the awards. There was one exception to the general refusal to try the ordinary engines. The last engine in the above list—that of Messrs. Brown and May—was an ordinary portable. It is evident it would have been unfair in the judges to have enforced their requisition; for, as only one or two of the larger firms exhibited their ordinary engines besides the ones specially built fo

Towards the conclusion of the above trials on Saturday, the judges wished to test the ordinary "commercial" engines of the firms whose "racers" had achieved the excellent results indicated in the tables. This request placed those eminent makers who could afford the expense of getting up "racers" in a somewhat difficult position. Their ordinary engines would have had to compete against their own "racers"—namely, engines, furnished with double-expansion valves, water-heating apparatuses, an extra number of tubes, mid feathers in the firebox, firebricks partly covering the grate, racing, those whose commercial engines were absent, would have been at an advantage.

Want of space compels us to defer publishing our notice of the trials of the steam cultivators threshers, and hand-dressing machines till next week.

Messrs. Aveling and Porter's traction engine has obtained the first prize silver medal, at the exhibitions held during the current month, at both Odense and Hamburgh. There were four competitors for the prize at the former, and eight at the latter, show.

ON A PACKING FOR PISTONS OF STEAM ENGINES AND PUMPS.*

By Mr. GEORGE M. MILLER, of Dublin.

THIS packing consists of two rings, pressed outwards against the cylinder by the pressure of the steam as it acts on the alternate faces of the piston, without the use of any springs. This construction of piston is used by the writer in the locomotive engines on the Great Southern and Western Railway of Ireland. The piston is of cast iron; 2 in. in thickness and 15 in. diameter. Two square grooves are turned in the edge of the piston, ⅜ in. in width and ¾ in. apart, and a corresponding steel ring is fitted into each groove, the rings being divided at one part with a plain butt joint, and sprung over the piston into their places. Two small holes, ¼ in. diameter, open from each face of the piston to the bottom of the nearest groove, whereby the steam is admitted behind the packing ring and presses it out against the cylinder so long as the steam is acting upon that face of the piston. The alternate action of the two rings is continued as long as the steam is acting on the piston, one of them being always pressed steam-tight against the cylinder.

Another form of the piston has been used in cases where the piston is desired to be flush on both faces or to fit a cylinder with flat covers; in this a circular flat head forged upon the piston rod is fitted between the turned faces of the two halves of a cast-iron piston, which are held together by turned pins riveted over, forming a hollow piston flush on both faces, fast upon the piston rod, and without any loose part besides the two packing rings.

The ends of the rings, where divided, are made either with a butt joint or a lapped joint. The piston body is turned to pass through the cylinder easily; and the joints of the rings have been found to be practically steam-tight. In some cases the joints have been tongued, as shown, but in the writer's experience this has has not been found requisite; the butt joint has invariably worked well, whilst it has the advantage of perfect simplicity of construction. In pistons where the packing ring travels over the opening of the cylinder port, a small stop is fixed in the bottom of the groove, entering a short slot in the packing ring, to prevent the ends of the ring coming opposite the cylinder port, but still leaving the ring free to travel round a little in the piston grooves; but it is preferred for the packing rings not to travel over the cylinder ports.

These steam-packed pistons have been used more than seven years in the locomotives of the Great Southern and Western Railway, and have proved so satisfactory and advantageous that their use has been extended to all the 94 locomotives working upon that line. The following are the results of the working in the engines running from Dublin, as regards the durability of one set of rings, the period of their wear, and the mileage of the engines whilst wearing them out. Nineteen engines working with one set of steel rings averaged 33,020 miles and 16½ months' running, one engine having worked for 3 years and run as much as 98,073 miles with one set of packing rings. Five engines working with one set of brass rings under the same circumstances averaged 30,986 miles and 19 months' running, the greatest work amongst them being 2¼ years and 43,197 miles. Twenty other engines with steel rings, which are still in use, have also averaged 40,444 miles and 21 months' work, one of these having worked for 3¼ years and run 94,899 miles with the original set of rings.

The general result of the above is that one set of steel packing rings have lasted 37,000 miles and 19 months' work, and one set of brass rings 31,000 miles and 19 months' work, the difference in durability being about 16 per cent. in favour of the steel rings. In some of the individual cases of the pistons with steel rings, a very considerable variation from the average result of 37,000 miles is found in the durability of the packing rings, some of them having lasted 2¼ times the average, and some only as much below the average. In the cases of the brass rings the variation is not so great, amounting to 1¼ times the average in the highest, and about as much below the average in the lowest. This variation in wear has not been fully accounted for: it may have occurred from a different character of metal in the cylinders, from priming of the boiler, and from the presence of grit in the water; but the writer has reason to believe that the rings have been frequently put in to work and set with a pressure upon the cylinder from their own elasticity, thus causing a source of wear. It is found the best plan to turn the rings to the exact diameter of the cylinder, and to put them in without any spring upon them, so that they are not subjected to any wear except when the steam is acting on them. The steel rings are now slightly tempered, to admit of their being sprung into the grooves without altering their form. In all these pistons the steel packing rings were ⅜ in. thick originally, and ⅜ in. wide, and they were worn down to about ⅛ in. thick in the thinnest part before being removed. The brass rings are worn down from 7-16ths in. until they are ¼ in. thick. Specimens were exhibited of steel rings from four engines that have worked 38,000, 61,000, 84,000, and 96,000 miles respectively, since first put into the pistons. It must be remarked, that, when opportunities occur, as when engines are under repair, the rings are taken out and reset to the size of the cylinder.

It is found in practice that two steam ports of ¼ in. diameter are quite sufficient for each of the steel packing rings. The rings must be made to fit easily in their grooves, so as to move freely, with a clearance of 1-16ths in. at the bottom of the grooves for the steam to pass round behind the rings. No difficulty has been experienced from the steam passages becoming stopped up a moderate use of tallow in the cylinders.

The use of this piston-packing in locomotive engines has been productive of economy by reducing the friction, and by prolonging the wear of both pistons and cylinders. It will be observed that only one ring is in action at the same time, and that when the steam is shut off, as in descending inclines and approaching stations, the piston is free to move without any friction. The cylinders of the four engines from which the specimen rings exhibited have been taken, show a highly polished surface, are very little worn, and are nearly parallel throughout. The operation of putting in these rings so as simply to fit the cylinder is extremely easy, whilst great care and skill are required in giving springs the requisite degree of elasticity, and in making them with maintain it.

A set of brass packing rings was also exhibited, taken out of the pistons of a pair of vertical stationary engine cylinders at the Dublin Railway station, in which they have been in constant work for the last four years, with a pressure of 50 lb. steam. The diameter of the cylinders is 19½ in., and the rings were originally ⅜ in. thick and ⅜ in. wide; they are now worn down to 5-16th in. thick.

A number of stationary engine pistons are working with these packing rings, and they have proved very durable and thoroughly satisfactory, giving an advantage in reduction of friction, and in preserving the cylinder face in perfect condition. In one case of the engine of the Oldbawn Paper Mill, near Dublin, with vertical cylinder 18 in. diameter and 2½ ft. stroke, working with 50 lb. steam, the cylinder had previously been worn considerably out of truth and much grooved, and one of these pistons was put in having two steel rings of ⅜ in. width and ⅜ in. thickness, and was in constant work for four years without the packing rings requiring renewal. They have lately been taken out for examination, and were found to be still ¼ in. thick; and the cylinder from its previous defective condition, has been brought completely to truth throughout, with a highly polished surface.

These packing rings have also been used for four years for pump buckets, and have proved very satisfactory. In one case of a double-acting pump 8 in. diameter, the two packing rings are of brass, ⅜ in. wide and 5-16ths in. thick; and are pressed out by the pressure of the water acting at the alternate faces of the bucket through two ports, ¼ inch diameter, similar to those in the steam pistons. This pump had two years' constant work at quarries and bridge foundations upon the Great Southern and Western Railway, before the packing rings required renewal.

In the case of single-acting pumps the bucket has only a single packing ring with ports opening from the upper side. A pump bucket 5 in. diameter has been working constantly for 2½ years at a station on the railway near Dublin. This bucket was exhibited, having been taken out for the purpose; the packing ring was originally ⅜ in. wide and ¼ in. thick, and has worn less the 1-16th inch in the 2½ years that it has been working up to the present time. As the diameter in this case is too small to allow of the ring being sprung over the body of the bucket into its place, it is put in by means of a junk ring screwed on at the under side of the bucket.

An application of the same construction of packing that has also been made to the gland packing of a 9 in. pump plunger, in which two brass packing rings are used, ⅜ in. wide and ⅜ in. thick, just like the piston packing rings, except that they act in the opposite direction, being pressed inwards upon the plunger by the pressure of the water through the ports.

Mr. Miller exhibited specimens of the steel packing rings from the pistons of four locomotives which had run from 38,000 to 96,000 miles; and also the brass packing rings from the pistons of the stationary engine, together with the bucket of the 5 in. single-acting pump referred to in the paper.

During the discussion which followed, Mr. J. Fernie said he was glad that the subject of packing rings for pistons, which were such an important part of a steam-engine, had been brought forward in the paper just read. He observed that steel packing rings had not been found to wear well in other instances in which they had been tried, and moreover they cut the cylinders; and he inquired whether the cylinders in which the steel rings had been working for so long a time were made of a very hard quality of metal.

Mr. Miller replied that the cylinders were cast as hard as they could be made, consistently with allowing of the subsequent boring. The packing rings were made of common shear steel, and sometimes wore down irregularly in thickness, but in many cases the wear was regular.

Mr. J. Fernie asked how the steel rings were made.

Mr. Miller said the steel was rolled in lengths of the required shape, but slightly tapering in section from the outer to the inner face, so that when bent into a circle the two edges of the ring became nearly parallel, giving the same depth of ring throughout its whole thickness. The bar was then bent in a miniature plate-bending machine, hammered to the size of the cylinder, and fitted into the groove in the piston by simply filing, without any other work being spent upon it. At first the rings were turned in a lathe out of a steel cylinder and then cut across, but it was found better to get steel rolled of the proper section for the purpose, and afterwards bend it and fit it by filing.

Mr. F. J. Bramwell inquired what amount of spring was given to the packing rings before they were put in their place, and whether the piston had ever been tried without admitting the steam behind the rings, in order to see how far it would be rendered steam-tight by the pressure of the rings alone without the steam behind them.

Mr. Miller explained that the packing rings were put in without any amount of spring of their own, being made no larger than the diameter of the cylinder, in order that there might be no pressure against the cylinder and therefore no wear whilst running with the steam shut off.

Mr. J. Fernie remarked that the steel packing rings in Mr. Ramsbottom's piston, generally

* Read before the Institution of Mechanical Engineers: Charles F. Beyer, Esq., in the chair.

three in number, were set with a certain amount of spring in themselves, by which the required pressure against the cylinder was obtained; and that plan required the cylinders to be of rather hard metal to stand the constant pressure in working. He inquired whether the brass packing rings that had been used had been adopted for the purpose of working in soft cylinders.

Mr. Miller said the rings first used with this mode of packing were brass, and after some time a set of steel rings was tried, the experiment being proceeded with rather cautiously from fear that the steel rings might cut the cylinder; but it was found they did not do so, if fitted in without any spring whatever in the rings themselves, but with only the steam behind pressing them against the cylinder. The result was that it very rarely occurred now that a cylinder required reboring: the cylinders not only preserved a fine smooth surface, but kept more parallel than under the old modes of packing the pistons. The reason of using the steel rings and discarding the brass was that the steel lasted about twice as long.

Mr. J. Fernie asked what was the weight of the steam-packed piston for a locomotive cylinder of 15 in. diameter.

Mr. Miller replied that the weight of a piston of that diameter was 64½ lb. without the rod, which was 2¾ in. diameter; the piston was 2 in. thick.

Mr. J. Fernie said they had tried some pistons on the Midland Railway on this principle of packing by the pressure of steam behind the rings; they were wrought iron pistons forged solid on the piston rods, and the packing rings were of brass ½ inch square in section. A very long mileage was got out of these rings, but it was found that with solid pistons there was a great deal of trouble from the necessity of getting the cross-heads off to draw the piston out, whenever it was wanted to do anything to the piston or look at the packing rings; and they had therefore now gone back to the old-fashioned piston with a junk ring bolted on the face for getting at the packing rings. The bearing surface was now reduced to 1 in. in the pistons; there were two ½ in. packing rings, and these gave a longer mileage than used to be got out of two 1¼ in. rings. A great width of bearing surface was not required, but a small bearing surface was preferable, provided the rings were made to fit the cylinder accurately all round; and Mr. Ramsbottom certainly had the credit of having first called attention to the advantage of narrow packing rings well fitted. The 16 in. piston now used in the Midland locomotives weighed 1¾ cwt., including the piston rod, having been reduced in weight 28 lb. below the previous make, in consequence of which a longer mileage was got out of the packing rings; the wear of the cylinders was also greatly reduced, a highly polished surface being maintained. Formerly there used to be a great deal of trouble from the cylinders wanting reboring, but now with the narrow packing rings and light pistons this was quite removed. He thought highly of the steam-packed piston, and the results obtained in the durability of the packing rings were certainly very extraordinary, 90,000 miles far exceeding any mileage previously attained. In his own experience about 20,000 miles was the durability of a set of ½ in. square brass rings, and then they would want setting up twice or three times during that period. He inquired how often the the steel packing rings had been set up before they were worn out.

Mr. Miller said the packing rings had not been examined and set up at stated times, but whenever the engine happened to be in for casual repairs the piston was taken out, and the rings examined and set out if required, by slightly hammering them all round to bring them again up to the exact diameter of the cylinder; or they were replaced by new rings if worn out. The results of mileage with the different sets of rings were drawn from a return of the exact mileage of all the engines that were working under his own observation.

Mr. F. J. Bramwell thought there would always be nearly the full pressure of the steam behind the rings that there was in the cylinder, judging from the quickness with which the steam filled the cylinder of an indicator through a small orifice.

Mr. Miller said that with the brass packing rings first tried the holes behind the rings were drilled ¼ in. diameter, but that size was found too large, and they were therefore reduced to ⅛ in. diameter, which proved to be sufficient for obtaining the required pressure to make the piston steam-tight in the cylinder.

The Chairman inquired whether the piston body was turned much smaller than the cylinder or only an easy fit.

Mr. Miller replied that the piston body was turned down to about 1-32 in. smaller diameter than the cylinder, so as to pass easily through it.

Mr. F. J. Bramwell asked whether the packing rings filled out to the size of the cylinder as they become worn, or whether when the steam was off they returned to their original inside diameter.

Mr. Miller replied that when taken out after a great deal of wear the packing rings were slightly smaller in diameter than the cylinder, and then required setting out by hammering. Sometimes they wore perfectly equally all round, and sometimes more at the ends or in the middle.

After some further discussion, the Chairman remarked that, after making and employing a great many descriptions of pistons, he thought the steam-packed piston described in the paper was a very good one, and it had the great advantage of being very simple in construction. Formerly, it was a great object to keep the steam out of the piston, on account of the internal packing springs; but in this piston the steam was admitted inside to act as the spring upon the packing. The practical feature of the new pistons was their great simplicity of construction; but to Mr. Ramsbottom was certainly due the credit of first simplifying the construction of pistons to so great an extent. He considered the piston now described ought undoubtedly to work well, because there was so little about it to get out of order, and it could not do otherwise than prove highly satisfactory. He proposed a vote of thanks to Mr. Miller for his paper, which was passed.

SPIGHTS' HORSE-HOE.

THE annexed engravings represent an invention recently patented by Mr. J. Spight, of Glandford Briggs, Lincoln. The invention is an improvement on one for which Letters Patent was granted in 1859. In that patent the hoes were attached to

FIG. 1.

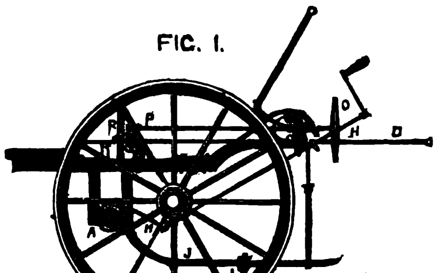

FIG. 2.

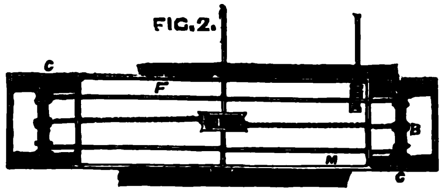

levers connected with a revolving shaft, working in a slide frame having bearings at each end, and which shaft could be raised or lowered as required for different kinds of corn or roots. The present improvement consists in suspending the shaft or bar to which the hoes are attached upon a bearing at its centre, instead of at each end, so that when one end is raised by turning a handle or otherwise, the other end is lowered in a corresponding degree, and thus when working over ridged or curved surfaces, or along what are called "lands," the depth or bite of the hoes may be regulated by the attendant with the greatest nicety.

Fig. 1 is a side view of the implement; fig. 2, a plan of the top frame, hangers, brackets, and steering shaft.

In fig. 1 the horizontal shaft P moves a wheel Q which works into the rack R. This rack is attached to the balance frame M, which works between the guide plates N, and which is raised or lowered by the steerer turning the wheel O. C, C, are brackets in which the hangers B move, and which also carry the revolving shaft A, to which the hoe-levers J, J, are attached. It will be seen that the hoes can be made to work on a level, or one end can be raised higher than the other when desired by the steerer if he is working on uneven or ridged land.

GOULDING'S PLOUGHS.

THE invention hereafter described has been recently patented by Mr. W. Goulding, of Leicester.

The invention has for its object improvements in ploughs. For these purposes the land side of the body of the plough in place of being upright, or as nearly so as may be in respect to the sole of a plough, is formed in such manner as to incline from the sole over towards the furrow side of the plough; and the beam where it is fastened to the body, in place of being directly over the land edge of the sole, comes more over towards the furrow side edge of the sole of a plough, by which the plough will be in a better state of balance and equilibrium than heretofore. The invention will be fully understood by referring to the engravings.

Fig. 1 is a side view; fig. 2, a plan; fig. 3, an end view of a portion of a plough, constructed according to this invention. *a* is the body or frame of the plough, shown separately in fig. 4, which is

FIG. 1.

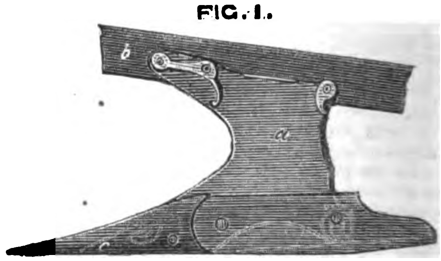

FIG. 2.

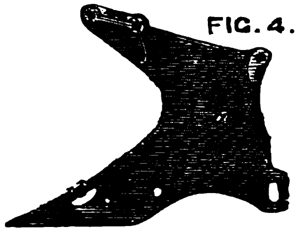
FIG. 3.

FIG. 4.



fixed to the beam *b*, and has secured to it the mould board, the slipe with the sole, and also the share, as is usual, but instead of being upright in relation to the sole, as usual, it inclines over from the sole towards the "furrow side" of the plough. The beam *b*, instead of being directly over the land edge of the sole, is brought more towards the furrow side, by which means a better balance and equilibrium is obtained in working than heretofore. *c* is the share, which fits on the nose of the frame or body of the plough; and *d* is a hooked rod or bolt, which passes into a hole in the share, and thence back

into an opening formed to receive it in the projection e of the frame, where it is tightened up by a nut; the projection e is also provided with a hole to receive a bolt for securing the hind part of the mould board. Another hole is formed in the frame or body a of the plough, for receiving the bolt which secures the forward part of the mould board.

The sole and slipe are cast together; this piece is connected to the body or frame by two bolts, one serving as a centre or axis, and the other passing through a slotted hole; this second bolt has an eccentric upon it, which bears upon a projection, so that by turning this eccentric round (when the nuts are slacked) the inclination of the sole can be varied.

THE STEAM PLOUGH ON PUBLIC TRIAL.

BY way of introduction to the Worcester trial-fields, and in order that our readers may rightly appreciate the status of steam culture at the approaching great competition of 1863, let us cite some of the main feats hitherto accomplished on such occasions.

Leaving out of view the ponderous steam-horse that used to "astonish the natives" with its lumbering tumbling "shoes," or "endless rails," and half-a-dozen ploughs following in its track; and omitting also, all notice of the travelling engine with rotary delver at its tail, which, first in one form and then in another, has from time to time surprised the public by bits of beautiful tillage that, unfortunately, never became anything more extensive than "bits;" and without devoting space to the mention of all the sets of wire-rope apparatus that have appeared at the Royal Meetings, we will just recapitulate a few of the principal facts reported by the judges concerning one or two of the best steam ploughs now before the world as candidates for public favour.

At the Chelmsford Meeting, in 1856, both Mr. Fowler and Mr. Smith of Woolston competed with machinery on the stationary engine principle. The rate of Mr. Smith's novel process of "smashing up" with a 7-horse portable steam-engine, was computed by the judges to be less than 4 acres in 10 hours, costing 8s. per acre for wear and tear, interest of capital, and all expenses. In the adjourned trial at Boxted Lodge, Mr. Fowler's engine, working up to 21-horse power, ploughed well at the rate of 7¼ acres in 10 hours, at a total cost of 7s. 2½d. per acre, including interest, wear and tear, and removal (which latter item was reckoned at no less than 17s. 6d., with a half-day lost every third day). This was for work valued at 7s. an acre by horse-labour.

In 1857, the steam-ploughing machinery was self-travelling from field to field (excepting in cases of very steep hills and unduly awkward turnings), and at the same time appeared the system of hauling an implement between a moveable engine on one headland, and a self-moving anchorage on the other. The work done was declared equal in excellence to good horse-ploughing; but the unsuitable nature of the ground precluded any satisfactory determination of the economy of performance.

Next year, at Chester, very marked progress was displayed. The Woolston cultivator, with stationary 8-horse portable engine and windlass, manufactured by Messrs Howard, broke up and then cross-scarified heavy land at the rate of 3½ acres in 10 hours (for the two operations); the total cost being 14s. per acre, for a condition of tilth that would have cost by horses at least 18s. 6d. Mr. Fowler's moveable 10-horse engine and anchorage ploughed light land at the rate of 7¼ acres in 10 hours; the total cost being 6s., instead of 8s. per acre, as by horses. The same machine ploughed "a strong three-horse soil" 6 in. deep, at the rate of five acres in 10 hours, at 9s. 2d., instead of 12s. 6d. per acre, as by horses—a saving of nearly 80 per cent. The interest and wear and tear were calculated at 20 per cent., divided over 200 days' work in a year; and the judges affirm that they charged each machine with a maximum of working expenses, while crediting it with a minimum value for the work performed. Double ploughing, or trenching 12 in. deep, was executed at the rate of 2¼ acres in 10 hours costing 18s. 4d. per acre; whereas horse-power could not have performed such perfect tillage at all, and by hand-labour it would have cost £6 13s. 4d. per acre, and yet have been inferior in value to the steam work.

At Warwick, in 1859, Messrs. Howard's Woolston apparatus "smashed up" in grand style a most obdurate piece of ground at the rate of 7 acres in 10 hours; and Mr. Fowler, with "digging breasts" attached to his three-furrow plough frame, "made a complete fallow of the hardest land at one operation," at the rate of 6¼ acres in 10 hours.

So far, perfection in the quality of the process had been attained; the point of economy was still open to further progress. A more systematic investigation of mechanical merits was instituted by the society's engineer and judges at Canterbury Meeting, in 1860, bringing out the following important results. In ploughing a strong loam (which, from the ascertained draught of a common plough at 6 cwt., would cost 12s. an acre if turned over by horses), "the least efficient of the competing machines (Beard's) showed a saving in total expense of 15 per cent.; both Robey and Co.'s and Eddington's machines showed a saving of 45 per cent.; and Mr. Fowler's work was done at a saving of no less than 68 per cent.," as compared with the cost by horse teams. Mr. Fowler's 12-horse engine, working with a pressure of 68 lb. on the square inch, drove four "3-horse furrows" at once, at the rate of 11 acres in 10 hours; and the total cost was computed to be 4s. 6d. an acre instead of 12s. (the lowest price by horse labour), though 20 per cent. upon the prime cost of the apparatus was allowed for interest and wear and tear. On the "strong land," where the draught of a single furrow represented the extraordinary traction-force of 7¾ horses, Mr. Fowler's machine ploughed up and down a hill having an average inclination of 1 in 10, in one place no less than 1 in 4½; the rate of performance being 6 acres in 10 hours, and the whole expense only 8s. 4d. per acre.

At these trials was also observed the time required for shifting engine and tackle, and "setting down" to a fresh field; about three-quarters of an hour elapsing between getting steam up to the pressure in one field and commencing tillage in another. This was a vast advance upon the "lost half-day" in 1856; and the engine being able to steam its own way from place to place, without the 6 or 8 horses previously needed, lowered the cost of removal to 4s., instead of 17s. 6d.

The prolonged Leeds trials in 1861 yielded a judges' report full of tabulated data and results. The principal feats were as follows. Mr. Fowler's 12-horse engine scarified at the rate of 6¼ acres in 10 hours, at a total cost of 7s. 2d. per acre, the depth being 7 in., and the soil very strong and stubborn. Messrs. Howards' 10-horse engine scarified the same soil 5¼ in. deep, at the rate of 6¾ acres in 10 hours, at a cost of 6s. 8d. per acre. It is impossible to place a money value upon this scarifying of whole ground into a deeply-pulverised seed bed at one operation, the bottom cleanly cut, the soil broken, and left light as by the spade; and further powdered and levelled, without the trampling of a horse, by a harrow hung loosely to one side of the grubbing or digging implement. The immense superiority of the tillage to any horse-work whatever was even more gratifying than the excellence of the regular turnover ploughing performed by the two most closely competing sets of apparatus. In the "heavy land" field, to plough a single furrow 8 in. deep required a draught equivalent to the power of five horses, yet Mr. Fowler's machine ploughed at that depth, at the rate of 5¼ acres in 10 hours, for the total cost of 7s. 10d. an acre. The most remarkable performance, however, was that of Mr. Fowler's stationary 8-horse engine and windlass, which ploughed a clover ley 6 in. deep, at the rate of 7¾ acres in 10 hours, the whole cost being 5s. 2d. per acre. The judges omitted from their calculation the expense of removal; but it was noted that while a "self-propelling" apparatus was "set down" and "loaded up again" ready for travelling for 4d. *per acre*, machinery demanding the assistance of four to six horses cost 9d. *an acre* for the same items of preparation for work.

The Farningham exhibition last year gave us no judges' investigation of the capabilities of the steam ploughs, but private observations made at the time are entirely at variance with the official announcement that the "cost of working, deduced from experiments at Boxted Lodge in 1856, is not now far from the truth." We have the authority of our own reporter (in the *Mark Lane Express* of that period) for the following statements. Messrs. Howard's stationary 10-horse engine, at 70 lb. pressure, ploughed at the rate of about 7¼ acres in 10 hours, and Mr. Fowler's moveable 14-horse engine, at 40 to 50 lb. pressure, ploughed at the rate of about 9 acres in 10 hours. This was a fair 3-horse work for a single furrow (as apparent from the depth and from the character of the land), worth at least 10s. per acre by the horse-plough, and estimating the expenses by the table in the Leeds report, the cost was from 6s. down to 5s. per acre. Mr. Fowler's moveable 10-horse engine, at 60 to 70 lb. pressure, also accomplished 7½ in. deep "digging" at the rate of about 12 acres in 10 hours, the cost probably under 4s. an acre; and his 14-horse engine scarified at the rate of about 30 acres in 10 hours, at a total expense of less than 2s. per acre—up to that time an unprecedented feat in steam cultivation. One lesson of the Leeds trials had been that very considerable motive power was economised by efficiently carrying the wire rope clear of the ground. An experiment there made showed that the draught of a length of rope trailing along the land was ten times greater than when the same rope ran over rope-porters, holding it clear of the ground; and, accordingly, at Farningham, Messrs. Howard, as well as Mr. Fowler, appeared with mechanism for tightening and upholding the "slack" rope.

Of the Yorkshire Agricultural Society's steam cultivation trials, in August, 1862, Mr. J. C. Morton furnished a very comprehensive report from which we glean the following main points. On a foul clover stubble, in light sandy soil (a small part hard clay), Mr. Fowler's single-cylinder 8-horse engine, working at probably 70 lb. pressure, ploughed 5 in. deep, at the rate of 10 acres in 10 hours. Where the proportion of clay was somewhat greater, Messrs. Howards' double-cylinder 10-horse power engine, at 70 lb. pressure, ploughed full 5 in. deep, at the rate of 7¼ acres for 10 hours.

A new method of comparing the work made by cultivators or scarifiers was tried on this occasion. A frame, 4 ft. by 4½ ft., inclosing an area of two square yards, was dropped here and there upon the several plots of work done, and the loose earth within the frame carefully collected and weighed. Messrs. Howard's 10-horse engine moved 680 tons weight per acre, at the rate of one acre, or 660 tons per hour. Mr. Fowler's 14-horse engine moved 650 tons per acre, at the rate of 1¾ acres, or 1,240 tons per hour, the daily work 18¾ acres. Though the weight moved per acre was less than in Messrs. Howard's case, Mr. Morton observes that the soil was completely tossed about by the high speed of the implement; whereas the Bedford cultivator merely moved what it broke up, so that a crossing would be required to make its tillage equal to that of the former. In fact, the weight of loosened earth per square yard or acre is a test of the depth of work, but by no means of the efficiency of the mechanical action to which the ground has been subjected.

In May and June last, Messrs. J. C. Morton and J. T. Harrison, C.E., conducted a series of dynamometer experiments with the Woolston, Leeds, and Bedford machinery. Their report having been but recently published in our columns, a word or two here will be sufficient. The circumstances of the trial can hardly enable us to draw a just comparison between the several machines. The Woolston tackle was not new, and was worked with comparatively few rope-porters. It does not appear, from the experiments with the Bedford tackle, how much of the draught of the slack-rope is returned again to the pulling-rope, by means of the compensating pulley on the double snatch-block. The data respecting the Leeds tackle seem ample enough, with one exception—the friction due to the anchorage pulley when the whole strain is on the rope was not ascertained. It is very remarkable that only three-quarters of a hundred-weight draught was needed in order to move 700 yards length of rope passing round and distended between the engine clip-drum and the anchorage pulley, and carried clear off the ground upon rope-porters. A 1 cwt. draught, at a speed of three and a half miles per hour, represents 1-horse power, the waste of motive power between the engine and the implement is, therefore, very small indeed.

We await now the Worcester trials, where perhaps a further investigation of mechanical merits and defaults will be made by the Royal Society's engineers.—*Mark Lane Express.*

The Government of India has sanctioned the sum of Rs. 2,48,738 for establishing telegraphic lines from Rajmahal *via* Maldah and Dinagepoor to Gowhatty, with a branch from Gowhatty to Sylhet and Cachar.

The American steam fire engine, "Manhattan," which was so severely injured by the accident at the Crystal Palace as to be unable to compete in the late trial, has now been repaired, and is to be publicly displayed at work in the grounds of the New River Company, at New River Head, Clerkenwell, on Saturday next, the 25th inst., at twelve o'clock noon. Very great interest is felt in scientific circles as to the capabilities of this celebr[illegible] machine, which is reputed to be the most [illegible] ful and efficie[illegible] the American [illegible] engines.

MERRYWEATHER AND FIELD'S IMPROVEMENTS IN STEAM FIRE-ENGINES.

Fig. 1.

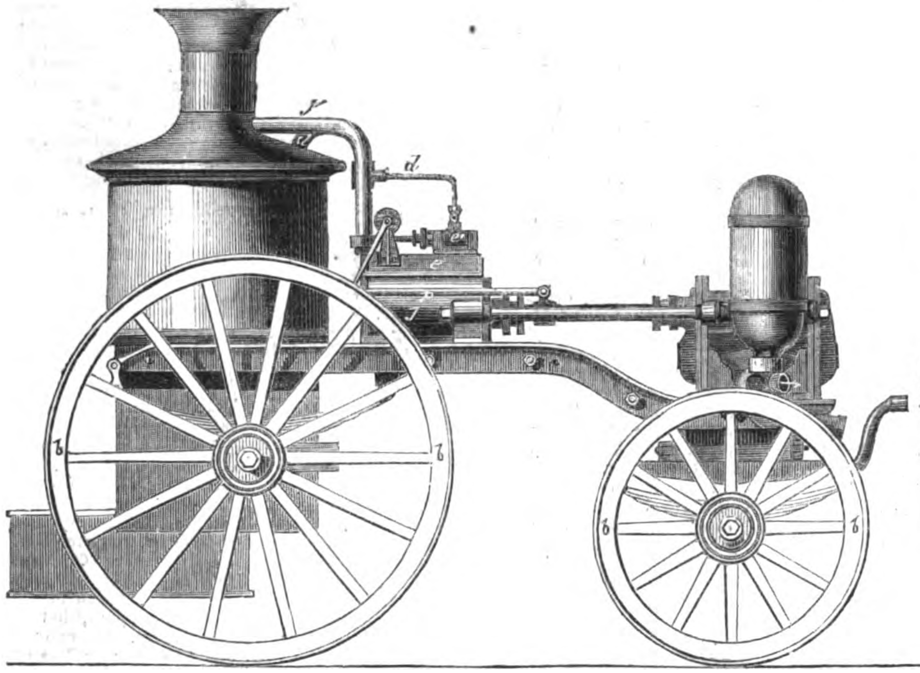


Fig. 2.

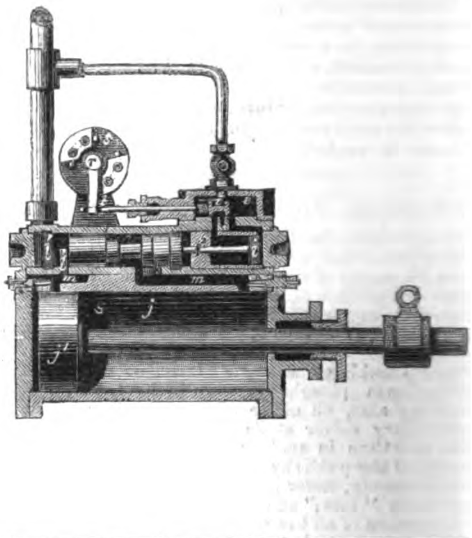

MERRYWEATHER AND FIELD'S IMPROVEMENTS IN STEAM FIRE-ENGINES.

The following inventions for improvements in steam fire-engines have been patented recently by Messrs. Merryweather and Field, and may be described as follows:—

The improved steam fire-engine consists of a framed carriage, mounted when intended for land service, on travelling wheels; at the hinder end of the frame is a boiler, in front of which is placed the steam cylinder and pump. The boiler consists of a vertical fire-box with water and steam chamber above, from the lower plate of which descend a number of tubes arranged around the entrance to the smoke flue, the lower ends of some of them converging inwards to bring them into more immediate contact with the main body of the fire. Within these tubes are smaller ones open at top and bottom, their upper ends being wide-mouthed or trumpet-shaped to facilitate the entrance and downward passage of currents of solid water, unaffected by the steam which rises externally around them. The exhaust pipe from the steam cylinder on entering the chimney passes downward to a chamber (the lower surface of which forms a baffle plate) from whence the steam is projected upwards to increase the draught in the fire-box. Provision is made for cushioning the piston in the steam cylinder, by causing it to pass beyond and close the main ports, the steam and exhaust being then led through a smaller channel capable of nice adjustment. Steam is admitted to the working cylinder of the engine by a slide valve, acted upon by a smaller steam valve which receives its motion from connecting rods attached to the piston rod of the engine.

Fig. 1 is an elevation of a single cylinder steam fire-engine for land service, constructed according to this invention; and fig. 2 is a vertical longitudinal section of the steam cylinder and valves appertaining thereto. The framing of the machine *a*, *a*, is formed principally of angle iron supported on springs, and carried by the travelling wheels *b*. The boiler *c* is attached to and carried by the framing at a level below the steam and water spaces, so that the bolts employed for fixing do not pass into either of them, thus avoiding liability to leakage. It communicates by the steam pipe *d* with the valve chest *e*, as also by a small pipe d^1 with the valve chest e^1, made use of for regulating the motion of the piston valve, whereby the ingress and egress of steam to and from the main cylinder are regulated. The construction of the cylinder and valves is clearly shown at fig. 2, in which the same letters are employed to indicate the same parts as in the other figures. The two pistons f, f^1, of a piston valve work in a suitable cylindrical valve chamber or chest *e*, into which steam is led from the steam pipe *d*. The rod f^2 of the piston valve is continued forward, and fitted with a small piston *i* working in a cylinder, to which steam is admitted alternately on each side of the piston as required by means of a small slide valve i^2 of ordinary construction. The valve chamber *e* communicates with the main cylinder *j* by means of four passages k, k^1, and l, l^1, which open into thoroughfares m, m^1, communicating respectively with the forward and backward ends of the cylinder. Small passages n, n_1, lead into the main thoroughfares m, m_1, and are formed with cocks for the purpose of regulating the escape of steam after cushioning. The action of the valve piston is regulated by means of levers o, o^1, connected by links p, p^1, with the piston rod, common to both the steam cylinder *j* and pump *q*. The levers o, o^1, communicate motion to a rocking shaft *r*, upon which is keyed a disc *s*, fitted with adjustable stops, which act alternately upon each side of a tongue lever *t*, taking into the rod of the slide i^2. In the position of the parts as shown, the piston j^1, propelled by steam (admitted through the opening *k* to its forward side), has just completed its backward stroke, and by closing the backward main port has caused the steam behind the piston to form a cushion, whereby the momentum of the piston has been checked sufficiently to avoid injury to the end or cover of the cylinder; while the steam forming the cushion has, at the same time, been gradually escaping through the opening *n* into the exhaust passage l^1. The piston rod during its backward action has given motion in that direction to the levers o, o^1, the shaft *r*, and disc *s*; the latter moving through a great portion of its arc without moving the tongue lever *t*. When, however, the corresponding adjustable stop has come into contact with the forward side of the tongue lever, the slide i^2 is immediately moved into the position shown, and steam is thereby admitted to the forward side of the small piston *i*, thus driving it backward, and carrying the pistons f, f^1, into the position shown by the dotted lines, and causing the piston j^1 to be moved in the contrary or forward direction; firstly, by the passage of steam through the small passage *n* to the back of the piston, which, upon passing, and thus laying open the back port, is continued in its forward motion by the full volume of steam entering thereby, until upon the piston *j* arriving near to its forward stroke, the piston *i* is again moved, and the contrary action takes place. It is obvious that the frame, boiler, and general arrangement herein represented and described with reference to this engine may also be applied to engines having two or more cylinders and pumps.

Fig. 3 is a vertical section of the boiler; and fig. 4, an enlarged section of one pair of the tubes detached. The fire-grate is of the ordinary or any other suitable construction, and is enclosed in a casing *v* depending from the water and steam space u, u_1. From the tube plate *x* depend and descend into the furnace a series of tubes x^1, curved or otherwise as found most convenient for the economical employment of the heat generated in the furnace. These tubes x^1 contain other tubes x^2, which are notched or otherwise made so as to be freely open at bottom, and are formed with enlarged trumpet-mouths at their upper ends, or are otherwise equivalently shaped, to deflect the steam and water ascending from the annular spaces contained between the inner and outer tubes, in such manner as to facilitate and not to interfere with the downward current of colder and solid water, descending by the inner tube to replenish that which has passed upward by evaporation or otherwise between the inner and outer tubes. This deflection of the upward current may be effected by various arrangements, differing more or less from the trumpet-mouth hereinbefore described and shown; as for example, by the use of a dish or cup-shaped top to the inner tube, or by an annular disc or washer, both of which are substantially equivalent to the trumpet-mouth.

The steam, after passing through the engine, as described, is carried off by an exhaust pipe *y*, which terminates in a box or chest y^1, having an opening opposite to the bottom of the chimney; from which opening the steam rushes upward, and increases the draught of air through the fire-grate; the lower side or surface of the box or chest acting at the same time as a baffle plate, deflecting the flame and heated gases, and preventing their too rapid escape up the chimney. The circumference of the tube plate *x* is bent downward so as to form an annular pocket x^3 for the collection of mud or sediment thrown up and ejected from the tubes, and which, after settling in the pocket, may be got rid of when required by openings provided for that purpose.

MERRYWEATHER AND FIELD'S IMPROVEMENTS IN STEAM FIRE-ENGINES.

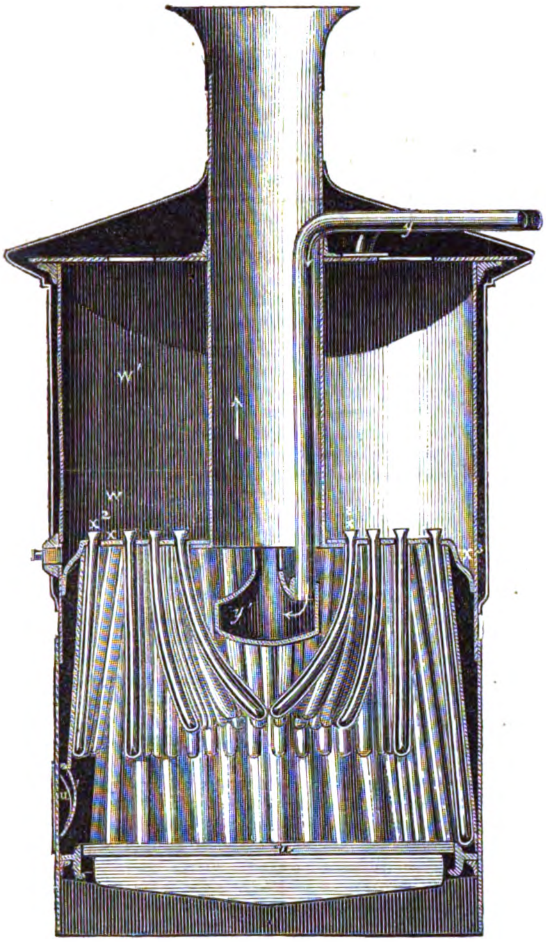

FIG. 4.

OILING WOOL BY MACHINERY.

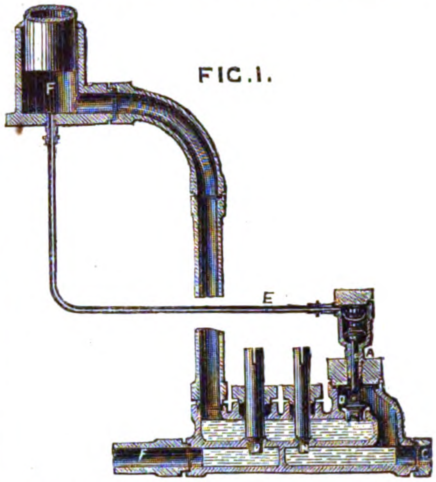
WE have had an opportunity of inspecting an invention by Mr. Leach, of the firm of Messrs. Littles, Leach, and Co., Britannia Mills, Leeds, which appears effectually to meet a requirement long felt in the woollen trade. In order to render wool more workable than it is in its native state, it is customary to oil it, a process which has the effect of causing the fibres to slip more readily and evenly, and ensures more perfect cording and regular yarn. Hitherto the oil has been distributed by hand from a syringe, watering-can, or similar instrument; and the result has been that the oil has been diffused very irregularly, in some places the wool being saturated and clotted, and in others escaping altogether. This inequality in the oiling of the wool produces similar inequality in the yarn, and the defects of the process are discernible in the various stages of manufacture. It is to obviate this difficulty that Mr. Leach's invention is intended. The invention has the advantage of being readily attached to willies, teazers, pluckers, burring, and other machines employed in the manufacture of wool, and is so constructed that it can distribute oil to any given extent, the machine measuring and distributing the liquid with unerring accuracy. As the wool passes along the feed-sheet of the preparing machine, the oil is, by means of the apparatus invented by Mr. Leach, scattered over it in the form of a spray or mist; and on examination afterwards we found that the wool was thoroughly oiled, a fact which could be detected by feeling the wool; but the oil having been so evenly and accurately distributed, was not perceptible to the eye. The quantity of oil can be varied at pleasure, and, by a simple arrangement, it can be conveyed to the machine in pipes from the cask or cistern, thus saving much labour and preventing waste. An invention of so much importance to the woollen trade, notwithstanding that it is said to be slow in adopting improvements in machinery, cannot fail to be universally acceptable.—*Leeds Mercury*.

BROWN'S HYDRAULIC PRESS.

A PATENT has just been obtained for an invention by Mr. J. Brown, of Sidney-street, E., for improvements in hydraulic machinery. The invention consists of a box containing a piston for the prevention of accidents in hydraulic machinery in the event of the main pressure, pipe breaking or engine stopping. This box as placed above the relief valve now in use, connecting the box by means of a pipe to the lifting cylinder or cylinders. In the event of the main pressure, pipe breaking or engine stopping, the pressure contained in the lifting cylinder or cylinders will at once act on the piston and cause the rod thereof to press upon the relief valve, thereby preventing the water escaping from the lifting cylinder or cylinders, and thus stop the running down of any weight the machinery may be lifting. The box and piston may be fixed at any other convenient place instead of above the relief valve now in use; but in such cases the piston rod has a mitre stop valve or clack fitted to it, which will act in the seat of the piston box and have the effect as above described.

The piston box A is shown as being fixed above the relief valve D, and connected by means of the

FIG. 1.



pipe E with the lifting cylinder F, in order that the pressure existing in the lifting cylinder may cause the rod of the piston B to descend and press upon the relief valve D whenever the pressure should be taken off the said relief valve D, either through the engine stopping or the breaking of the main pressure-pipe C. Another piston box G, fig. 2, may be used and fixed at

FIG. 2.

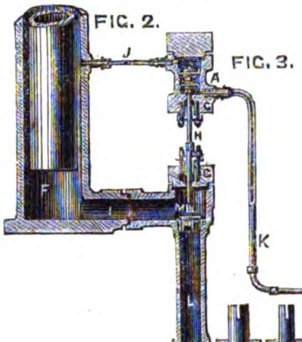


FIG. 3.

any other place than above the relief valve, and even used where there is no relief valve. This piston box G is connected with the lifting cylinder F by means of the pipe, I and J, connecting also said piston box G directly with the connetcion pipe L, and by means of the pipe K connecting the piston box G further with the main pressure, pipe C. The piston rod of the piston H carries a valve M, which is always kept in a lifted position by means of the pressure conveyed by the pipe K from the main pressure-pipe C to the piston H, thereby allowing the water to enter the lifting cylinder F or to run out of the same so long as no accidents happen; but as soon as the engine should stop whilst in the act of lifting, or the main pressure-pipe C break, then, the pressure ceasing to exist in the pipe K, the piston H would instantaneously descend by means of the pressure existing in the lifting cylinder F, which pressure would then be conveyed to the said piston H by means of the pipe J, and the valve M fixed to the rod of the piston

H would at once prevent the water running out of the lifting cylinder F, and the weight then being lifted would remain stationary. The pressure-valve N is used for the purpose of allowing the water to enter from the main pressure-pipe C into the lifting cylinder F; and the exhaust valve O, is used to discharge the water from the lifting cylinder F by means of the pipe P. Fig. 2 represents the piston H and valve M in the position it would be in the event of the engine stopping or main pressure-pipe C breaking.

RULES FOR THE CONSTRUCTION OF BLOWING FANS.

We have extracted the following remarks on this rather important subject from a French scientific publication.

Carefully-conducted experiments have demonstrated the accuracy of the following rules :—

The length of the blades or vanes should be equal to, or slightly greater than, half the radius of the complete fan.

When the air gains access to them on each side, their width should be a little greater than one-half the diameter of the orifice through which it enters. When the air is admitted to the fan-case at one side only, this width should be diminished by one-half.

The fan-blades should be inclined in the direction of their motion in such a way as to form an angle of about 18 deg. with a radius line passing through their inner extremities. The apertures for the entrance of the air should form circles a little larger than that described by the inner ends of the blades. They should be slightly eccentrical to the fan-shaft, inclining towards the delivery-trunk.

It is of the last importance that the fan should be carefully centred, and accurately balanced.

The noise usually produced by these machines may be somewhat diminished, by fitting a kind of trumpet-mouth of sheet iron to the central orifice.

They are best made without spokes or arms, by rivetting half-vanes on each side of a central disc.

REMARKABLE CHANGE OF FORM IN METALS.

Lieutenant-Colonel H. Clerk has contributed a Paper on the above to the last number of the Proceedings of the Royal Society. He was led to conduct some experiments on the subject by the following circumstance :—When, a short time ago, the workmen at the Royal Arsenal, Woolwich, were about to shoe a wheel with a hoop-tyre, to which it was necessary to give a bevel of about three-eights of an inch, one of the men suggested that the bevel could be given by heating the tyre red-hot and then immersing it one-half its depth in cold water. This was tried and found to answer perfectly; that portion of the tyre which was out of the water being reduced in diameter. The tyre was 3 in. wide, ½ in. thick, and 4 ft. 2 in. in diameter. As this result was curious and not generally known, Colonel Clerk considered it desirable to institute some further experiments, in order to try how far, by successive heatings and coolings, this change of form could be augmented, and also whether the same effect could be produced on other metals than wrought iron. The experiments were made on cylinders of wrought iron of different dimensions, both hollow and solid—immersed some to one-half of their depth, others to two-thirds; also on similar cylinders of cast iron, steel, tin, zinc, and gun-metal. With wrought-iron the heatings and castings could be repeated from fifteen to twenty times before the metal showed any signs of separation; but with cast iron, after the fifth heating, the metal was cracked; and the hollow cylinder separated all round just below the water line, after the second heating. Cast steel stood twenty heatings, but was very much cracked all over its surface. As respects the change of form of cast iron and steel, the result was similar to that in wrought iron, but not nearly so large in amount. The cast iron did not return to its original dimensions; but the smallest diameter was about 1 in. above the water line. Tin showed no change of form, there being apparently no intermediate state between the melting point and absolute solidity. Brass, gun-metal, and zinc showed the effect slightly; but instead of a contraction just above the water line, there was an expansion or bulging.

THE MAIN DRAINAGE OF LONDON.

The Main Drainage works were visited on Saturday last by a large number of distinguished persons. The *Times* shortly describes Mr. Bazalgette's scheme in the following words:—This great plan may best be briefly described as consisting of three gigantic main tunnels or sewers on each side of the river. These completely divide underground London from west to east, and, cutting all existing sewers at right angles, intercept their flow to the Thames, and carry every gallon of London sewage, under certain conditions, into the river on the north side below Barking, and on the south to near Erith. These main drains are called the high, middle, and low level sewers, according to the height of the localities which each respectively drains. The high level on the north side is about eight miles in length, and runs from Hampstead to Bow, being at its rise only 4 ft. 6 in. in diameter, and thence increasing in circumference, as the waters of the sewers it intercepts require a wider course, to 5 ft., 6 ft., 7 ft., 10 ft. 6 in., 11 ft. 6 in., and at its termination, near Lea river, to 12 ft. 6 in. in diameter. This drain is entirely finished, and in full work. Its minimum fall is 2 ft. in the mile; its maximum at the beginning nearly 50 ft. a mile. It is laid at a depth of from 20 ft. to 26 ft. below the ground, and drains an area of fourteen square miles. The middle level, as being lower in the valley on the slope of which London is built, is laid at a greater depth, varying from 30 ft. to 36 ft., and even more below the surface. This is nearly complete, and extends from Kensal Green to Bow. The low level will extend from Cremorne to Abbey Mills, on the marshes near Stratford. At Bow the low level waters will be raised by powerful engines at a pumping station to the junction of the high and middle level ducts, thence descending, by their own gravity, through three tunnels to the main reservoir and final outfall below Barking. These three tunnels are each 9 ft. 6 in. in diameter, and nearly four miles long. Great engineering difficulties existed in the construction of these main arteries, as, from the height at which they all meet, it was necessary to take them above the level of the marshes leading to Barking. For a mile and a-half the embankment which encloses the three tunnels is carried on brick arches, the piers going 18 ft. below the surface, and being based on solid concrete. In the marshes at Barking the reservoir for the reception of the sewage of the north side is formed. This reservoir is a mile and a-half long by 100 ft. wide, and 21 ft. deep. It is made of this great length in proportion to width to allow of its being roofed with brick arches, which are again covered with earth to a considerable thickness, so that not the slightest smell or escape of miasma can take place. This is capable of containing more than three times the amount of sewage which can enter it while the pipes are shut, and thus, when all is complete, the works will not only be large enough to take off all London's sewage now, but its sewage when in London is double its present size. While the sewage is in the reservoir we have spoken of, it will be completely deodorised by an admixture of lime. When the tide is at its height, the sluices which pass from the bottom of the reservoir far out into the bed of the river will be opened, and the whole allowed to flow away. It takes two hours thus to empty the reservoir, by which time the tide will be flowing down strongly, and will carry its very last gallon a distance of thirteen miles below Barking, which, being itself thirteen miles below London, will place the contents of the sewers, every twelve hours, twenty-six or more miles distant from the metropolis. Thus, instead of letting loose the rankest of this great city's abominations in the very midst of London, and leaving it to stagnate, or, still worse, to be agitated backwards and forwards in a small body of water, it will all be carried away a distance of thirteen miles, then deodorized, then suffered to escape into a body of water more than a hundred times greater than that into which it now crawls, and thus disinfected and diluted, so as to be without either taste or smell, swept still further down the stream, till every trace of it is lost. On the south side the three great sewer arteries are constructed on similar plans—the high level from Dulwich to Deptford; the middle from Clapham to Deptford; and the low level from Putney to Deptford. At this point is a pumping station, which raises the water from the low to the high level, whence it flows away through a 10 ft. tunnel to Crossness Point. One part of this tunnel, passing under Woolwich, is a mile and a-half in length, without a single break, and driven at a depth of 80 ft. from the surface. At the outfall will be another pumping station, to lift the water to the reservoir. The southern reservoir is only five acres in extent; that on the north is 14. In the reservoir it will be deodorized and discharged in a similar way to that we have already described.

It was over these last-named works, amid an apparently inextricable labyrinth of culverts, arcades, chambers, and columns, that the visitors were conducted, first inspecting the channel for the overflow of storm-water, next the two culverts, as large almost as railway tunnels, which carry the sewage to the east and west pumping stations. Before the entrance to the pumps are massive iron strainers, which keep out all the coarse refuse brought down the sewer, and which is afterwards dredged up by the filth-hoist into the filth chamber, which is flushed into the river at low water. The pumping-house is nearly finished, and the iron-work of the engines begun. The pumping stations will each consist of an engine-house, containing ten boilers calculated to work up to 500-horse power nominal. This power working through eight pumps of 7 ft. diameter and 4 ft. stroke will daily raise 19,000,000 cubic ft. of sewage from 19 ft. below low water to the level of the outfall; but, in case of necessity, the pumps can raise 25,000,000 ft. per day. The reservoir into which it will all flow is not yet finished, but when roofed in with brick will hold 20,000,000 gallons of sewage. After inspecting these works on Saturday the visitors were taken across the river to the Barking outfall, where the works are larger, simpler, and much more advanced, for on the north the sewage is brought at such a level as to discharge into the reservoir by its own gravitation. The reservoir here is far advanced, a great deal of it being roofed in, so that it will all be completed in a few months more. Close to this the contents of the high level sewer were turned on into the river direct, and not as they will in future flow, through the reservoir. The inspection of this murky Niagara of sewage, as it came tumbling down, seemed to be not at all unpleasant to members who are accustomed to legislate in hot weather on the banks of the largest sewer in the world—the Thames. After gazing on this unsavoury volume of dirt for some time, by way of an appetiser, the whole party returned to the great reservoir to lunch. In the afternoon the visitors returned to town, having enjoyed an agreeable, and, we may add, an instructive excursion.

The total strength of the three rows of intercepting sewers, the course of which we have sketched on each side of the river, will be fifty miles, and before all the works are completed 800,000 cubic yards of concrete will be consumed, upwards of 300,000,000 of bricks, and 4,000,000 cubic yards of earthwork.

M. Rouher has obtained the signature to a decree directing that a Universal Exhibition shall be held in Paris in 1867, opening on the 1st of May and closing on the 1st of October.

TO CORRESPONDENTS.

HENRY KERR.—Your letter is too long for insertion. It lies at our office for you.

E. T.—Your invention is simple and ingenious.

W. G. F. (Stockton.)—Write to the Secretary Gt. George-street, Westminster.

RECEIVED.—W. F., W. B., H. K., E. T., W. G. F.

W. F.—We have no doubt that you will learn with some surprise, that your invention has been patented in precisely the same form you propose years ago.

D. K.—We have not as yet been able to get accurate replies to the questions you wish answered.

Correspondence.

[*We do not hold ourselves responsible for the opinions of our correspondents.*]

STEAM FIRE-ENGINES.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Having seen Messrs. Lee and Co.'s challenge, I beg to say that I am willing to meet them or the makers of any American steam fire-engines, or the makers of any English steam fire-engines with or without American improvements, in *fair* competition.

But, as weight is not the only property of a good fire-engine, I respectfully suggest that the following points should be taken into consideration at any future trials, viz:—

Adaptability for rapid travelling over rough roads and turning sharp corners.

Capability for carrying men, hose, ladders, and other gear.

Facility of raising and generating steam.

Facility of drawing water from depths, without priming or charging pumps or pipes, or inserting foot valves in the suction pipes.

Quantity delivered at various pressures, or through various sized nose pipes as compared with the theoretical capacity of pumps.

Simplicity of construction; accessibility to the various parts of engine, pump, or boiler; and lastly,

Cost at which it can be produced.

Should these conditions be accepted, I am quite willing to produce my engine, the "Princess of Wales" (the one that was too heavy for the class it was intended for, had to work against engines four or five times its power, and was highly commended at the late trial), at such time and place, and for such sum as may be agreed upon between us.

WM. ROBERTS.

Millwall, July 21, 1863.

RAILWAY ACCIDENTS, AND THEIR CAUSES.

SIR,—I have read with much interest the article on "Railway Accidents," and hope the subject, which is one of great importance, will meet with due consideration from engineers and directors, so as to reduce the number of what may fairly be considered avoidable accidents, or rather damages to railways, which proper care and precaution will lessen if not wholly prevent. I feel assured—after thirty years of working practically amongst the railways of England—that the care of the permanent way and its safe gauge, on which all its true working depends, is too much in the hands of simple labouring men, who are neither sufficiently nor efficiently superintended or directed, in their work of repairing or relaying permanent ways. Another point is the too frequent taking up and relaying of sleepers of permanent way—consequent on their quick and in some cases rapid decay and rotting—and the great risks of accidents consequent to the same, and which often leads to imperfect gauges being laid, owing to the hurried nature of the work and inefficient inspection. The time is not far distant when "permanent ways" will be really so in work as well as in name; but where wood sleepers, and inferior of their kind, are now often introduced on railways for (so called) economy, it cannot be permanent in any way or sense; and the gauge or width-space of rail paths, and space between, should be at all times uniform throughout to secure safety in "quick speeds" which is the desideratum.

Yours respectfully,

PRACTICAL.

Miscellanea.

It is stated that after a rather protracted inquiry the Government have assented to the proposal of Mr. Cave, M.P., chairman of the West India Committee, and agreed to remit the Customs' duty on methylated rum, in order that it may be used as a desiccant for paint in the same manner as spirits of turpentine, the price of which has been seriously enhanced by the American war. The methylation is to be performed in bond, and the differential duty of 2d. on colonial, and 5d. on foreign spirit, imposed for the protection of the British distiller, is still to be paid.

The *Times'* Correspondence of yesterday contains a valuable letter on boiler explosions. The views enunciated by the writer are in accordance with our own, expressed a couple of weeks ago. While advocating careful inspection, however, the writer proposes that it shall be accomplished by the formation of voluntary associations, rather than by Government interference.

Mr. Milholand, of the Reading Railroad, U.S., once proposed to light his workshops, employing 700 men, with gas made from old greasy cotton waste, &c. The proposed apparatus would have cost about £250; and we have little doubt the scheme was quite practicable.

Divers have walked more than a mile under water 100 ft. deep.

Cast steel slide valves have been often used in locomotives.

The use of caloric engines of small size seems to extend slowly in America. These machines possess many advantages where but a trifling amount of power is required.

Japanese coal measures about 37 cubic feet to the ton. It is extremely smoky, contains little sulphur, and forms in burning from 40 to 50 per cent. by bulk of clinker. It evaporates 4·5 lb. of water for each pound consumed in a marine boiler of ordinary construction. We do not imagine that it will ever prove of much service to our Navy.

We learn from *Le Monde* that a submarine vessel, "Le Plongeur," has just completed a very successful voyage from Rochefort to the Island of Aix, under the command of Captain Bourgois, who designed the boat. This first experiment has proved the regular working of the machine under the action of compressed air, the ease with which the crew can live and work in an artificial atmosphere, and the rapidity and ease with which the boat can be manœuvred. In a few days all will be ready for definite trials, from which the happiest results are expected.

A trial trip of a new despatch steamer or *aviso*, lately built by Messrs. Money Wigram and Penn, for the Italian Government, took place on Monday. The new boat, which is constructed on similar lines to one built by the same firm for the King of Italy a few months since, is 250 ft. in length between perpendiculars, 30ft. in breadth, and carries engines of 350-horse power. They are of 5 ft. stroke, and their cylinders are 71 in. in diameter. The paddle-wheels are over 23 ft. in diameter and are fitted with feathering floats. As in most boats constructed by Messrs. Penn, the engines are oscillating, and the boilers are on the tubular system. The trip extended from Tilbury Fort, to a little beyond Sea Reach, and the speed attained in running the measured mile was at the rate of 17 knots, or 19·6 miles an hour. As the "Messaggiere" starts for Genoa, she had already taken on board over 180 tons of coal, besides nearly the same amount of stores and spare gear, which caused her to draw almost a foot more water than she would have done under ordinary circumstances. With a normal load there appears to be little doubt of her running at a speed of 17¼ or even 17½ knots an hour—a swiftness hardly ever yet gained by the fastest of the many fast boats launched from Messrs. Penn's yard.

A Newcastle paper states that a novel lifeboat, the building of which was commenced at Tow Law, on the 10th of March, is now nearly ready for sea. The builder is a working man, which may partly account for the delay that has taken place in the completion of the undertaking. The boat is almost wholly composed of iron, and she is expected to be self-righting, being arched over the top with sheet iron, and propelled by three screws, one of which lies midships, so that the quick heaving to which lifeboats are subjected cannot throw the screw out of the water unless she turn keel up. Her length is 15 ft. by 4 ft. 2 in. broad. The screws are to be driven with levers, so as to imitate the motion of rowing with oars, which boatmen are daily used to. The boat is now lying at Washington.

The following appeared in yesterday's *Times*:—Two hundred tons of armour-plates are now being delivered at Portsmouth Dockyard by vessels from France, the manufacturers being Messrs. Petin, Gaudet, and Co., the makers of the armour-plates for the frigate "La Gloire," and the other iron-clads in the French Imperial Marine. 100 tons are of 4½ in., and have been purchased by our Admiralty at £45 per ton. The remaining 100 tons are of 5½ in., the price being £50 per ton. Like all the other French plates which have been supplied to the English Government, these from Petin, Gaudet, and Co., have a very rough, blistered, and unfinished appearance; but this may not detract at all from their cohesiveness or shot-resisting power. They are, however, such plates as the Admiralty would not receive on any terms from English manufacturers. The latter, indeed, are loud in their complaints, and have been now for some time past, of the restrictions the Admiralty place upon them in compelling them to give their plates such a perfectly even surface, and to bestow upon them such an immense amount of "trimming and polishing." They say that the plate is ruined in its defensive quality as ships' armour, and that they therefore do not compete with the French makers on equal terms. In the previous trials of plates at Portsmouth, furnished by Messrs. Petin, Gaudet, and Co., and M. Schencking, of Toulon, the plates themselves, although roughly manufactured, showed an extraordinary degree of resisting power to the 68 lb. solid shot at 200 yards range, and the metal of which they were composed was evidently of a very superior quality.—Competition is all very well; but our own iron manufacturers should take some steps to see that in this case, at least, it is conducted on principles of perfect equality.—ED. M. M.

Mr. T. Collins sends us the following:—"In your last number is a paragraph reporting some remarks of Mr. B. Cochrane, in the House of Commons, on the proposed Lighthouse at Great Bass Rocks, Ceylon. I happen to know something of this matter, the most mismanaged I ever heard of. I went out in March, 1856, to Ceylon in the same vessel as the engineer, a very young and erratic, though pleasant fellow: the subject being very interesting to all naval and travelling people, he displayed his plans and explained them—the drawing exhibited an iron lighthouse, with granite substructure, let in some feet into the Bass Rock; all was settled as to the erection, but he candidly acknowledged that the rock had not been surveyed for 8 years, and that no regular report had even then been made, the "account" of the liable authorities and fragmentary information being all that was available. "Whether the rock was of granite was rather uncertain, it was supposed to be 8 ft. above (tranquil) water at its highest point, its extent was probably diminished, and the possibility of excavation for building of course not known." This was his statement, and all turned out wrong, the rock would not take the building, and any operations at all on it, even at the best seasons, were almost impracticable. When I left the island in 1858, I saw the engineer again, and he told me (what everybody there knew) that beyond imperfect surveying and abortive attempts to work the rocks, nothing had been done. A wretched steamer had been bought, and was found useless, and he was waiting more means. Since then nothing of moment seems to have been accomplished in this most important matter. I may finish by informing you that an English vessel was wrecked on the Basses while I was in Ceylon."

Mr. Grove, F.R.S., has delivered a lecture before the Chemical Society, describing his researches on the action of heat on liquids. Amongst others, he mentions the following experiment:—A long glass tube, closed at one extremity, was bent in the middle nearly to a right angle; the closed limb was then half-filled with water, from which, by long boiling, the air was supposed to have been expelled; the remaining space in the tube was then completely filled with olive oil, and the opened extremity dipped into a basin of the same. Heat was then applied to the tube until the water boiled, and this temperature maintained for a considerable time. Each bubble of steam which left the surface of the water passed through the column of oil, becoming smaller and smaller during its ascent; but never did it condense without leaving a microscopic bubble of gas, which at length accumulated so that it could be examined. This bubble was found to be pure nitrogen. Similar experiments were made with bromine, chloride of iodine, &c. The general conclusion Mr. Grove derived from his experiments was to the effect that water had a very powerful affinity for the gases of the atmosphere; that, by several processes, the oxygen could be eliminated, but that the nitrogen resisted all attempts to expel

it from solution—so much so, that it might be doubted whether chemically pure water (a compound of two elements only) had ever been prepared; and, further, that ebullition (as applied to water) under all circumstances, consisted merely in the production and disengagement of bubbles of aqueous vapour formed upon a nucleus of permanent gas.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 3354.
Boilers and Furnaces, 3384.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 3352.
Ships and Boats, including their fittings, 3361, 3403.
Cultivation of the Soil, including agricultural implements and machines, 3376, 3377.
Food and Beverages, including apparatus for preparing food for men and animals, 3396.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 3355, 3359, 3360, 3366, 3373, 3383, 3385, 3388, 3392, 3394, 3395, 3401, 3407, 3409.
Buildings and Building Materials—none.
Lighting, Heating, and Ventilating, 3353, 3363, 3368, 3371, 3380, 3382, 3391, 3405.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 3349, 3356, 3357, 3358, 3364, 3378, 3379, 3400, 3402, 3406.
Metals, including apparatus for their manufacture, 3351, 3375, 3397, 3398.
Chemistry and Photography, 3387, 3389, 3400.
Electrical Apparatus—none.
Warfare, 3367, 3399, 3404.
Letter-Press Printing, 3365.
Miscellaneous, 3350, 3361, 3362, 3370, 3372, 3374, 3386, 3390, 3393, 3408.

3349. W. Phelps. *Improvements in locks.* Dated December 15, 1862.

These improvements are as follows:—In the axis of the keyhole is a hollow spindle, carrying at either end a disc, the disc on one end of the said spindle being circular, and the other disc being of the figure of a circle, with a portion cut away through about a quadrant. The cut away portion is of a circular curve, but of less radius than the other portion. A shoulder or tooth is formed by each junction of the part of large diameter with the cut away part. The said discs are of somewhat greater radius than the acting part of the key, and have each a hole cut in it for the introduction of the key. The turning of the key effects the turning of the discs. In the lower part of the lock and between the discs a lever works. The said lever turns at one end on a centre, and its other end carries a projecting block which is made to bear on the periphery of the toothed disc by the action of a spring. The said block is toothed both on its upper and lower sides, its teeth engaging with those on the disc, and preventing more than a partial rotation of the discs so long as the lever remains in its normal position. The upper edge of the said lever on which the key acts is deeply indented at the part opposite the key hole, so that when the key is introduced into the lock, that part which is formed to act on the lever enters the said indentation. The said indentation in the upper edge of the lever has on either side the figure of a convex curve, so that the key cannot be turned in either direction without coming in contact with one of the curved parts of the lever. The motion of the lever upwards is limited by the before-mentioned projecting block bearing against the periphery of the toothed disc, and its motion downwards is limited by a stop. The action of the several parts is as follows:—When the key is introduced and turned in either direction, it acts on the curved part of the lever, and depresses the said lever sufficiently to permit the discs to rotate, the toothed projecting block on the lever being depressed out of the range of the teeth on the toothed disc. The key and discs having freedom of motion, the bolt of the lock is shot or withdrawn by the key in the usual manner. If a false key is introduced into the lock, it either depresses the lever too much or not enough. If it depresses the lever too much, the said lever is arrested by the stop, and the key cannot rotate; if it does not depress the lever enough, the teeth on the projecting block engage with the teeth on the toothed disc, and prevent the rotation of the discs and key. The action is the same whether the key is introduced from one or other side of the lock. When the key is left in the lock in any other position than that at which it may be drawn out, the keyhole on the other side is closed. *Patent completed.*

3350. M. Hyams. *Improvements in the manufacture of cigars, cheroots, and cigarettes, and in the treatment of tobacco.* Dated December 15, 1862.

In manufacturing cigars and cheroots, the inventor inserts in the bunch a piece of carbon or charcoal which acts as a filtering medium. *Patent abandoned.*

3351. E. B. Wilson. *Improvements in machinery or apparatus for rolling metals.* Dated December 15, 1862.

This invention relates to a peculiar construction and arrangement of conical rolling mill, and consists in driving one roll direct from the main shaft by suitable gearing, the other roll being driven direct from the first roll by intermediate gearing; or it may be found that the pressure applied to the rollers will be sufficient to drive the second roll, in which case the intermediate gearing may be dispensed with. One of the rolls is adjusted either by screw, cam, or hydraulic power. In the case of rolling hoops, tyres, and similar articles, in order to keep them perfectly circular, the inventor places one, two, or more guide rollers in the plan of motion. *Patent abandoned.*

3352. R. Kirk. *Improvements in machinery or apparatus for checking or stopping the motion of railway carriages.* Dated December 15, 1862.

Under one modification or system of arrangements, the axles of each carriage are formed with a small crank at the central part. These cranks are made, by preference, about half an inch to an inch in depth, and each crank is connected to the contiguous axle by a connecting rod which rises and falls with the rotary motion of the axles to an extent corresponding to the depth of the cranks. Above each connecting rod is fitted in the framing of the carriage or other suitable part a wheel, a portion of the periphery of which is removed so as to form a flattened surface. This flattened part of the wheel is, under ordinary circumstances, or when the apparatus is not in use, immediately over the connecting rod, and so that the rod in its reciprocatory motion just clears the under surface of the wheel. The spindle to which the wheel is fast extends outwards in a lateral direction sufficiently far to admit of the convenient attachment thereto of a small vertical lever. These small levers throughout the train of carriages are each connected by means of chains, or other suitable couplings, one to the other, the two end extremities being connected to hand levers which are respectively within convenient reach of the engine driver at the head of the train, and of the guard in the rear. With this arrangement of apparatus, when the train is proceeding safely, the chains hold the several wheels securely in position with the flattened parts above the connecting rods; but when it becomes necessary to stop the train quickly, the engineer or the guard slackens the chains by means of the hand lever, which admits of the wheels turning to a slight extent, and their peripheries act as so many wedges, and fix tightly the wheels of the several carriages, which are thus simultaneously held fast, and the train is very quickly brought to a standstill. *Patent abandoned.*

3353. J. McInnes and E. F. Prentiss. *Improvement in the distillation and treatment of petroleum and other like oils.* Dated December 16, 1862.

This invention has for its objects the distillation and treatment of petroleum and other like oils, by a continuous process, and in a film or shallow layer or layers, and consists in evaporating the oil upon a series of heated inclined planes of various temperatures, and which surfaces the patentees prefer to cover or partially cover with a layer of cast-iron filings, borings, or turnings, or any other suitable metal, or other good conductor or conductors of heat, to increase the heated surfaces into which the oil to be distilled is brought in contact. They also propose in some cases to use a thin layer or stratum of mineral or vegetable charcoal, lime, burnt clay, sand, or other deodorizing or partially deodorizing and purifying material, resting upon the heated inclined planes. Each of these heated inclined planes are enclosed in or form the bottom of an air-tight vapour chamber. *Patent completed.*

3354. J. Farley and J. Crowther. *Improvements in steam engines, and apparatus connected therewith.* Dated December 16, 1862.

We cannot here give space to the details of this invention. *Patent completed.*

3355. G. C. Warden. *Improvements in ornamenting textile fabrics, leather, and other surfaces, in a cement employed therein, which is also applicable to the waterproofing of fabrics and materials, and in apparatus for applying and spreading such waterproofing cement.* (A communication.) Dated December 16, 1862.

This invention consists in ornamenting textile fabrics, leather, and other surfaces, by fixing thereon by means of the waterproof cement hereafter named, or by any other cement which becomes adhesive on the application thereto of heat, various designs, patterns, or devices cut out or stamped in silk velvet, leather, or other desired material. Another part of the invention consists in producing by means of lithographic or other engraving shaded effects upon the design to be fixed as aforesaid. Another part consists in the employment of silk or other fabric previously dyed of a colour to resemble that of the parts of the object forming the subject of the design to be fixed as aforesaid; for instance, if the design is to consist of a rose and leaf, the inventor takes pink or red silk for the rose, and shades the same by engraving, and green silk and shades it also to represent the leaf. The cement which forms part of the subject of this invention, is composed of the following materials in or about the following proportions; that is to say, seven parts of gutta percha, two parts of resin, and one part of solution of caoutchouc, mixed by dissolving them together under heat. The apparatus for applying and spreading the cement, whether in the designs or objects for ornamenting surfaces or for waterproofing, consists of a vessel or trough with overhanging sides, to which heat is applied to render the cement sufficiently fluid. The lower part of the vessel is formed or provided with a long narrow outlet closed by a roller free to revolve in adjustable bearings. The cement is rendered sufficiently fluid, and the material on which it is to be spread is drawn over the roller and in contact with it, when a coating will be evenly spread all over one face of the material. When the coated material is to be used for the ornamenting of any surface, it is placed thereon, and heat from an iron cylinder or otherwise is applied with pressure. When the cement is applied for waterproofing then a second material has to be employed, and which is caused by heat to adhere to the cement spread on the material as aforesaid, so that the cement may be enclosed between the two fabrics or materials. *Patent abandoned.*

3356. J. S. and S. Hancock. *Improvements in garotte knives.* Dated December 16, 1862.

This improved knife is made with two dagger blades at each end, both acted upon by one spring, which holds them when in the open position, the blades being released when it is required to close them by raising the end of the spring out of the notch in the blade. Or a catch may be used, acted on by the spring and released by pressing a small projection. The guards at each end of the handle, instead of being fixed to the scales, and projecting at right angles thereto, as is usually the case (and which makes the knife bulky and inconvenient to be carried), are fastened by pins to the blades close to the ends of the scales, and when the blades are closed, they close also, spontaneously turning upon the pins and lie along the blades parallel to the scales, and quite out of the way, but spring into their former cruciform position as soon as the blades are opened. *Patent abandoned.*

3357. O. Dickin. *An improved table fork.* Dated December 16, 1862.

Provisional protection has not been granted for this invention.

3358. J. J. Lemon. *Improvements in book trays or holders.* Dated December 16, 1862.

This invention relates to improvements in the construction of book trays or holders for the purpose of holding in position a series of books, and for their conveyance from place to place. These improvements consist—1, in constructing a series of levers, springs, and guide rods, by means of which the slide or slides and flaps of the tray can be opened for the purpose of inserting or removing books. For operating on double slides the levers are formed somewhat in the shape of a pair of scissors, and jointed in a similar way by a pin passing through the slide or edge of the tray, their handles extending outside the tray. Attached to the inner ends of these levers are rods working in slots at the under side of the tray, and moving the slides accordingly. In order to bring the slides back after the removal or replacement of a book, springs are attached from two corners of the tray to these levers. These springs may consist of spiral wire, flat curvilinear steel, or other known form of spring, suitable for the purpose; but for a single acting slide only one lever will be necessary with one spring attached. *Patent completed.*

3359. W. and A. Smedley. *Improvements in machinery or apparatus for the manufacture of textile or looped fabrics on warp lace machinery.* Dated December 16, 1862.

This invention relates to the employment of a stump guide or stump guides in addition to the guide or guides at present used in warp lace machines. The patentees employ one such stump guide to each of the guides in present use in ordinary warp machines (that is to say, the guides carried by one or more of the common guide bars in such machines), and they attach the stump guides to an additional bar or bars, that is to say, to a bar or bars employed in addition to the bars in present use; or they cast the stump guides in leads and screw the leads to a bar or bars which they attach to a common guide bar or bars in such manner that the two bars will move simultaneously, such movements being effected by a wheel or wheels, or by equivalent contrivances, or by a jacquard at either end of the machine. *Patent completed.*

3360. W. Hudson, H. Moore, C. Catlow, and S. Newbury. *Improvements in looms for weaving, and in arranging the warps therein.* Dated December 16, 1862.

This invention relates—1, To a method of diminishing the shock of the pickers. To accomplish this the inventors adapt a strap or similar apparatus to the front of the slay, which strap passes over two pulleys, and its ends are connected to buttons mounted upon the picker spindles. When one of these buttons is struck by a picker it draws the strap over the pulleys, and the other button is then ready to receive the blow of the other picker. Another part of this invention relates to a method of tightening the warp when the weft is to be driven up, and of loosening it when the shed is to be made. For these purposes they employ a roller above the warp beam, around which, as well as around the usual roller, a cord is passed. This additional roller is mounted so as to be caused to vibrate from the crank shaft or other moving part of the loom. Another improvement relates to a method of causing the slay to vibrate. For this purpose they dispense with the usual connecting rod, and cause the crank pin to move in a slot carried by the slay. In drawing in the warps the usual method for plain work is to take the first and third and the second and fourth, but according to this invention they take the first and second and the third and fourth. In working the healds, therefore, the first and third rise and fall together, and the second and fourth. *Patent abandoned.*

3361. J. L. W. Thudichum. *Improvements in collecting human excreta, and in the apparatus and means employed therein.* Dated December 16, 1862.

This invention relates to a mode or method of collecting the human fæces and the urine separately, the main object being the preservation of such excreta separate from each other. According to one mode of carrying out this invention, as applied to water-closets in connection with drains and sewers, it is proposed to so construct the pan of the closet, that the fæces shall fall into one compartment and the urine into another, the pan being divided by a transverse partition for that purpose. The compartment which receives the solid excreta is constructed similar to an ordinary water-closet, and opens into a drain-pipe leading to the sewer. The front compartment for the reception of the urine is connected by a pipe with a conduit or separate drain-pipe fitted into any convenient portion of the main sewer, so that the urine discharged into the closet will always remain separate from the other contents of the sewer. *Patent abandoned.*

3362. G. C. WALLICH. *Improvements in apparatus to be used in deep sea sounding for ascertaining the pressure and for raising specimens of the water.* Dated December 16, 1862.

This invention is carried out in the following manner:— For the purpose of ascertaining the pressure of the water, a strong cylinder or vessel is closed at one end by a fixed bottom, and at the other it has a moveable piston fitting water-tight within it. Inside the vessel the inventor places a mass of a solid compressible material, such for example as india rubber; this compressible material does not entirely fill the space within the vessel, but room is left around the solid for an incompressible or nearly incompressible liquid, such as mercury, and with this the remainder of the space is filled. When the vessel is lowered to a great depth into the sea, the heavy pressure of the water upon the outer surface of the piston causes it to move inwards, the compressible mass being made to occupy a smaller and smaller space as the pressure around it is increased. The liquid within the vessel ensures the pressure being applied to the solid mass equally in all directions. A record is kept of the distance the piston enters the vessel by placing on the rod or stem of the piston (which works between suitable guides) a projection, which, as the piston descends, moves a slider along a graduated scale conveniently placed on the side of one of the guides. When the instrument is drawn up after having been sunk, the position of the slider in respect to the graduations on the scale shows the pressure, and also the depth to which the instrument has been sunk. In order to bring up specimens of water from any required depth below the surface, the inventor suspends from the sounding line a horizontal cylinder open at each end; the cylinder is fitted with caps which, however, when the cylinder is lowered, are not in their places, but they are held in positions above the axis of the cylinder. They have india-rubber springs, which tend to draw them together; they are, however, unable to approach each other because the cylinder is between them, and keeps them apart. When the apparatus thus arranged has been sunk to the depth from which it is desired to raise a sample of water, a messenger weight is placed on the sounding line, and allowed to run down it; when it arrives at the apparatus, it strikes bars connected with the two caps, and pushes them down to the level of the cylinder, and when they are truly concentric therewith, the springs draw the caps together, and thus close accurately the ends of the cylinder. Suitable guides are employed to ensure that when the caps are pushed down they shall come truly into position to be drawn on to the ends of the cylinder by the springs. *Patent abandoned.*

3363. R. SCHOMBURG and A. BALDAMUS. *Improvements applicable to all kinds of oils used for illuminating purposes, whereby combustion thereof is rendered more perfect, smoke prevented, and the purity of the light increased.* Dated December 16, 1862.

This invention consists in leading the vapour from water to all kinds of oils while burning in lamps, whereby combustion is rendered more perfect and the purity of the light increased. The heat generated when the wick is lighted causes the vapour of water to ascend in a hollow cone or conical chamber round the wick-tube, and issue in contact with the flame about or above the point of its generation. A thin film rises from the water vessel up a narrow channel or space between two cones or conical caps with apertures through or between which the flame passes. The water vessel is by preference surrounded by another vessel or chamber between which a passage is formed through which air passes to the flame. *Patent completed.*

3364. H. JOHNS. *Improvements in clocks or timepieces.* Dated December 16, 1862.

This invention is designed for obviating the necessity for winding up clocks or timepieces periodically as at present practised. It is proposed to effect this through the agency of the variations in the temperature of the atmosphere, which are constantly taking place both inside and outside of dwellinghouses, and to employ the draught or current of air caused by such changes in temperature to set in motion certain mechanism to be connected to the ordinary mechanism of clocks, and by these means to produce a power sufficient to wind up a clock continuously, instead of having to wind it up by hand periodically, as at present practised. By this invention, a great part of the weight at present necessary to keep the going parts of a clock in motion may be dispensed with. *Patent completed.*

3365. R. HATTERSLY. *Improvements in apparatus for classing printers' types for composing machines.* Dated December 17, 1862.

This invention has reference to a previous patent, dated June 26, 1857, No. 1794. In performing the present invention, the patentee makes use of an inclined and curved table provided with channels or grooves, corresponding to the number of letters, figures, or other type to be classed. The entrance to these channels or grooves is widened to afford facility in placing the type therein, and at the entrance of some of the channels or grooves rows of shoots are applied to economize space. The type is deposited by hand into the entrances of the channels or shoots. Each channel or groove is furnished with springs or weights, to guide the type and prevent it from turning during its passage to the receiving sticks, which are made of angle brass, or other sheet metal. When the type has dropped into these receiving sticks, it is pushed forward by a cross bar acted upon by a crank, driven by a handle or otherwise. When these receiving sticks are charged, they are removed into a tray, ready to be taken to the composing machine. *Patent completed.*

3366. W. TONGUE. *Improvements in machinery and processes for preparing fibrous materials.* Dated December 17, 1862.

The first part of this invention consists in a particular method of working machinery for preparing fibrous materials, similar to that described in the specification of a patent granted to Henry Rawson, January 27, 1857, No. 249; and also in a particular method of working machinery for preparing fibrous materials similar to that described in a patent granted to the present patentee, dated March 5, 1862, No. 596. In this machinery a working comb is caused to rise and fall, and also to have a to-and-fro motion. Now, the present improvement consists in causing the working comb to have motion only in one direction, and to give the requisite motion in the other direction to the feed apparatus; that is so say, if the up-and-down movement is imparted to the feed apparatus, the to-and-fro movement will be imparted to the working comb; and if the to-and-fro movement is imparted to the feed apparatus, the up-and-down movement is imparted to the working comb. The second part of the invention relates to preparing machinery, in which rollers or other feeding instruments present fibrous material to the action of sheets of pins, screw gills, or other pointed surfaces continually moving or travelling through the fibrous material in one direction, and the improvements in this class of machinery consist in giving a reciprocating to-and-fro motion either to the feed apparatus or to the travelling toothed surface. The third part of the invention consists in an improved method of feeding stricks of fibrous material into machinery for preparing fibrous materials, such as is described in the specification of a patent granted to Henry Rawson, before referred to; also in an improved method of feeding stricks of fibrous material to machinery, such as is described in the specification of the patent granted to the present patentee, and before referred to; also in an improved method of feeding "stricks" of fibrous material to machinery, such as is described in the first and second parts of this specification. *Patent completed.*

3367. A. ALBINI. *Improvements in breech-loading fire-arms.* Dated December 17, 1862.

This invention consists of the improvements hereinafter described in opening the breech end of breech-loading firearms for the introduction of the charge, and in securely closing the same during the discharge. The patentee prolongs the breech end of the barrel beyond the discharge chamber to a length somewhat greater than that of an ordinary cartridge. The upper side of the prolonged part is open for a sufficient length to admit of the introduction of a cartridge. Upon the prolonged part there is a cap connected with a screw plug, which plug screws in the said prolonged part and closes it. A rod passes through a hole in the centre of the said screw plug, and terminates in the prolonged end of the barrel with a conical plug or closer, which plug or closer accurately fits the conical end of the charge chamber. The rod of the plug or closer is made semi-cylindrical, or of a prismatic figure, through the greater part of its length, its outer end being cylindrical and of small diameter. The hole in the screw plug, through which the rod of the closer works, is of the same figure as that part of the rod which passes through it. The projecting end of the rod is provided with a button or knob, by which the said rod can be pushed forward and withdrawn. When the rod is pushed home, and the plug or closer made to close the end of the barrel, the screw plug is turned by means of a handle attached to it, and the hole in the said screw plug is made to cross the end of the rod, and a shoulder on the said rod is thereby supported by the said screw plug, and the plug or closer firmly fixed to its seat. The firearm is then ready for discharge. To recharge the firearm after firing, the screw plug is turned a semi-rotation, so as to bring the opening in the said screw plug coincident with the rod of the closer. The said closer can now be withdrawn from the breech chamber and a fresh cartridge introduced. *Patent completed.*

3368. C. DEFRIES. *Improvements in the manufacture or construction of lamps.* Dated December 17, 1862.

A lamp made according to this invention has no body framing, or, in other words, offers no impediment to the rays of light. It may (as for galleries, piazzas, and other places where it is desirable to throw the light upwards) have a shadowless top or cover, similar to the body of the lamp. Or the cover may be made of tin, iron, or other material, and be of any shape or form, and be painted or enamelled in its interior. The patentee supports the lamp body principally by means of the gas pipe, whether the lamp be a street lamp or a bracket lamp (the means of support therefore being also the means of lighting). This pipe runs through the bottom glass of the lamp body upwards, till it breaks into horizontal radii or arms, which pass into a horizontal framing forming the top of the body of the lamp, so that (except in street lamps where the scroll above the capital assists) the whole lamp is supported by the centre or gas pipe. A further improvement in the street lamp is to place the carburator (with which it has of late become the practice to furnish each lamp) immediately under the body of the lamp, and just above the capital of the pillar or post; thus it is partially hidden from the passengers, and but little obstructs the downward rays of light. *Patent completed.*

3369. T. KNOWLES. *Certain improvements in machinery or apparatus to be employed in preparing and spinning cotton and other fibrous substances.* Dated December 17, 1862.

This invention relates to the machinery employed for preparing and spinning cotton and other fibrous substances, called roving and slubbing frames, throttles, and similar or equivalent machines, and is designed to effect the stoppage of the machine or a portion thereof by self-acting means in the event of a thread breaking. The invention consists in an arrangement of apparatus in which a rotating disc causes a reciprocating traverse of a sewing piece, one end of which is in connection with the stop rod of the machine, the other being attached to a bent finger, which is thus continually moved in and out of an aperture in the framing of the machine. Above these apertures a light lever is hinged in the said framing, and kept from falling over the aperture by the yarn or thread, which is made to support it, and, whilst in such position the machine can continue to work; but, if the thread become disunited, the lever falls, and prevents the bent finger from entering the aperture, and thus in stopping the sliding piece disconnects the driving power, and stops the faulty part of the machine. One such apparatus is applied to each thread or yarn. *Patent abandoned.*

3370. J. R. HAMPSON. *Certain improvements in the method of securing the extremities of the hoops or bands employed in packing bales, and in apparatus connected therewith.* Dated December 17, 1862.

This invention consists in the novel employment and use of studs or connections having two heads, one of which heads is cut away on each side of the centre to form a T-head. The apertures in each end of the hoop are formed like a straight slot, so that the studs are passed through the ends of the bands, the narrow way, and then turned half round, which prevents them passing back again, and which secures the ends of the band or hoop together. A second part of the invention relates to the punching of the holes in the loops, and it consists in the application of a crank or an eccentric to the ordinary form of punching apparatus, instead of the long levers at present employed. *Patent abandoned.*

3371. J. THORNE. *Improvements in apparatus for regulating the flow of gas to burners.* Dated December 17, 1862.

This invention consists of a valve fixed in a metal chamber, the lower part of which is attached to the supply pipe, and the upper part supplied with a gas burner. The valve is formed of a hollow tube having a set-off at its base, which is of enlarged diameter and capacity; inside this tube is another tube of smaller diameter, having an inverted cup attached to its outer surface at its upper end, so as to fall over the external surface of the larger tube, and rest on projections on the set-off or upper part of its base. This inner tube has a notched ring attached to the outer part of its cup, and is longer than the smallest part of the outer tube. An inverted cup of larger diameter than that which is attached to the second or inner tube is placed over this second tube, resting on the notched ring, and to this large inverted cup is attached a cup or disc of metal, or other suitable material, a little below the lower end of the second or inner tube. The valve in this position has its passage between the parts open through which the gas passes freely to the burner when the pressure is low; but if the pressure of the gas is more than equivalent to the weight of the large cup, they are raised, and the cup or disc is pushed up against the lower end of the inner tube, thereby shutting off that communication to the burner, and on the pressure further increasing the inner tube is raised, the cup or disc coming in contact with the under part of the set-off of the outer tube or seating of valve, the aperture through which the gas has to pass being decreased in size as the pressure increases, and on the pressure of the gas becoming less the parts which had been raised fall, and the apertures again open. *Patent abandoned.*

3372. J. RAMSBOTTOM and G. HACKING. *Improvements in machinery or apparatus for measuring and registering the flow of water and other fluids.* Dated December 17, 1862.

This invention relates to fluid meters, and consists in improved arrangements or contrivances for increasing the simplicity of structure, the accuracy of registration, and the general efficiency of those important instruments. The patentees dispense with the racked piston rod in those meters distinguished as the tumbler class, and thereby effect greater compactness and reduction to a direct, simple, and well supported form what has hitherto been a bulky and more complicated one. The invention cannot be described without reference to the drawings. *Patent completed.*

3373. J. W. HADWEN. *Improvements in machinery or apparatus for spinning, twisting, and doubling cotton and other fibrous materials.* Dated December 17, 1862.

This invention relates to mules and twiners, and consists in building the cop or bobbin upon a tube revolving upon a stationary spindle, the loose tube being put in motion in any desired manner. The stationary spindle is fixed on the top spindle rail, and the tube is made to revolve by a band from the ordinary pin, roller, or drum. The great advantage of this system consists in being able to run the loose tube at much greater speed and with less friction than the ordinary spindle, as much as 8,000 to 10,000 revolutions per minute, whereas the ordinary spindle only runs at from 5,000 to 6,000. *Patent completed.*

3374. T. C. BARRACLOUGH. *Improvements in machinery for spinning, twisting, and rolling tobacco.* (A communication.) Dated December 17, 1862.

This invention consists in an apparatus, hereinafter described, for spinning, twisting, and rolling tobacco at one operation. The patentee takes one or more rectangular or other shaped revolving frames or flyers, each provided with two pivots, one of which forms a hollow trunnion for the tobacco to pass through as it comes from the feeder, and the other carries a pair of driving pulleys, or other suitable mechanical means, for imparting rotary motion to the frame. Transversely to the revolving axis of the frame, and within it, is fixed a spindle which carries a bobbin on which the spun tobacco is rolled up. The bobbin is removed from the spindle in order to strip the roll of tobacco from it; and, for this purpose, one of the flanges is removed, which, when the bobbin is at work, is secured by screws or otherwise to its spindle. The equal distribution of the tobacco on the bobbin is effected by a guide travelling backwards and forwards parallel to the bobbin. *Patent completed.*

3375. F. DE WYLDE. *The protection and preservation of lead surfaces exposed to the action of water, and for the protection of such surfaces from decomposition by atmospheric action.* (A communication.) Dated December 17, 1862.

This invention consists in rendering lead surfaces insoluble in water by transforming the metallic lead into a sulphuret of that metal, thus preserving from corrosion pipes and cisterns exposed to the action of water, and roofs and other surfaces exposed to the alternate action of water and atmospheric air, and also preserving water in contact with such surfaces from contamination. *Patent abandoned.*

3376. L. Latter. *Improvements in ploughs.* Dated December 17, 1862.

This invention relates to an adaptation or combination of parts particularly adapted to ploughing up-and-down land without the necessity for turning the plough at the completion of each furrow. The operating parts of the plough—as the coulter, share, and mould plate—are formed in duplicate, and pointing in opposite directions. The portion of that part of each mould plate which, in ploughs, as generally arranged, is the hindermost, and effects the turning over of the soil, is removed, and in lieu thereof the patentee employs a bar or plate capable of turning near one of its ends on an axis of motion, and of being held in the required position to serve as a continuation of either mould plate to effect the complete turning over of the furrow slice. This bar or plate, at its outer end, carries cutters or seam pressers to cut or pare off a portion of the furrow slice, and allow it to fall into the furrow to receive the seed. The mould plates, from their junction with their shares, rise quickly from near a horizontal to a vertical line, or nearly so, by which advantage is gained, particularly in operating upon heavy land, in completely turning over the slice. The sole plate and other of each set of the operating parts of the plough incline upwards slightly from the centre of the sole plate, by which steadiness in working is obtained. The plough beam is similar at both ends, and has two pairs of supporting or carrying wheels, arranged so that when one pair is in operation the other pair may be out of operation. One of each pair of wheels is intended to run in a furrow, the other on the land. The draught is from the centre of the length of the combined plough by means of a lever or bar, which is capable of turning on such centre for the action of either set of working parts, and of being set as desired. One end of this lever or bar is formed with handles for the use of the ploughman, and the other for the attachment of the horses. *Patent completed.*

3377. R. Wheeler. *Improvements in ploughs.* Dated December 17, 1862.

According to this invention, in place of a single coulter, the inventor employs two or more coulters, producing as many separate slices, then the share follows, and the mould board turns over all the slices at once; thus the land becomes more thoroughly divided, and the air is better able to penetrate it. He also, according to this invention, attaches to a plough having a coulter or coulters, share and mould board, or mole or subsoil line, for stirring the land below the sole of the plough, at the same time that ordinary surface ploughing is effected. *Patent abandoned.*

3378. H. Burton. *Improvements in castors for furniture and other purposes.* Dated December 17, 1862.

In carrying out this invention the inventor proposes, instead of employing a wheel rotating on an axis set in a curved and moveable arm at the bottom of the socket of the castor, to substitute a globe or ball of brass, or other suitable metal or material, nearly one half of which protrudes through a circular aperture at the bottom and centre of the socket. Within the socket a circular plate or disc is to be placed, underneath which three or other number of projections in pairs are to be screwed or fixed, forming bearings for the reception of three or other number of similar but smaller metal or other balls, furnished with trunnions entering the bearings in the projections, these balls forming bearing surfaces for the larger ball. The disc is fixed in the interior of the socket by means of screws, and above the disc; the foot of the piece of furniture or other object is fixed by screws and glue or other adhesive solution. *Patent abandoned.*

3379. G. A. Huddart. *Improvements in buttons.* Dated December 17, 1862.

This invention is not described apart from the drawing. *Patent completed.*

3380. W. Clark. *Improvements in holders for lamps, candles, and other lights.* (A communication.) Dated December 17, 1862.

This invention relates to a means of supporting candles or lamps, or other similar lights, in such manner that the candle, lamp, or other light shall retain its vertical or normal position at all times, or nearly so, although the holder in which the lamp, candle, or other light is held is itself inclined in any direction. For this purpose the inventor applies a sphere to the candlestick or lamp holder, which sphere rests and supports the lamp or candlestick in a ring, or it may be an opening, in the upper and small end of a cone, such ring or opening being of a diameter less than the sphere; from the sphere depends a weighted rod or pendulum, the tendency of which to being always in a vertical position maintains the lamp or candle at all times in its proper position, although the cone stand or other holder may be oscillated or inclined to a considerable extent. *Patent abandoned.*

3381. C. J. L. Leffler. *Improvements in constructing armour for ships and fortifications.* Dated December 17, 1862.

For the purposes of this invention, the inventor employs bars of a width sufficient to form the thickness of the armour, and he places them the one on the other, so that the edges of the bars form the face of the armour. So far the arrangement is similar to what has before been proposed; but the inventor does not as is now usual form rivet or bolt holes through the bars, as such holes greatly weaken the bars, nor does he otherwise connect the several bars the one to the other throughout the whole length, so as to prevent their yielding when struck independently the one of the other, for a rigid mass is more easily penetrated by a shot than one that is able to yield to the blow; but he secures the bars at their ends by causing them to enter grooves in metal ribs or frames, which are attached to the main frame of the ship or structure. These ribs or frames are formed of metal bars rolled in one piece to the required grooved form. He does not attach the grooved ribs or frames to the main frame by through bolts, as this would weaken the frames, but he forms recesses in the grooved ribs or frames to receive the heads of bolts, and these bolts, where a timber backing is employed, pass through this backing to the frame behind. He makes each bar a compound bar—a bar of steel and a bar of iron welded together. The top bar of the series he forms much stiffer and thicker than the others, so that it may be able to keep the other bars in their places—thus the top bar becomes, in fact, a narrow armour plate, and it may be secured by through bolts in addition to the grooved ribs or frames before mentioned. In constructing armour plates he forms a pile of alternate plates of iron and steel laid one on the other until a sufficient thickness is obtained, and he welds these altogether, and such armour plates may be secured in their places by means of grooved ribs or frames retaining their ends. *Patent abandoned.*

3382. E. Precht and V. Toepken. *Making and packing friction matches.* Dated December 18, 1862.

Provisional protection has not been granted for this invention.

3384. J. Clayton. *Improvements in reverberatory furnaces for heating large masses of iron and steel, and in economizing the waste heat of the said furnaces.* Dated December 18, 1862.

In carrying out this invention, the patentee makes the middle of the furnace moveable, the said middle of the bottom of the furnace being supported on a carriage having four or other number of wheels. By this arrangement the bottom of the furnace can be wheeled away or drawn from under the reverberatory arch of the furnace, and the mass of iron or steel to be heated placed thereon. The moveable bottom may then be restored to its place under the reverberatory arch, and the mass of iron or steel heated. The heated mass may be removed on the moveable bottom to the rolls or other machinery by which it is to be rolled, hammered, welded, or otherwise operated upon. The carriage conveying the moveable bottom may be loaded with the pile or mass of iron or steel on the side of the furnace opposite to that at which the heated mass is operated upon; that is, the carriage being wheeled from under the reverberating arch, and the heated mass delivered on one side of the furnace, the said carriage is wheeled back under the furnace and out on the other side where the pile or mass to be heated is hoisted and lowered on the carriage. The cinder or slag produced during the heating of the iron or steel falls on the bottom of the furnace, which said bottom is made concave and inclined downwards from the middle towards either end. The melted slag or cinder is thus conducted to the ends of the bed of the furnace, whence it falls into two under waggons, one placed under the carriage at each end to receive it. The under waggons work under the carriage carrying the moveable furnace bottom. The carriage and waggons work on inclined tramways. The sides and bottom of the furnace are closed by doors. The doors closing the upper part of the sides of the reverberating arch open by a vertical sliding motion, and are supported on balanced levers. The doors closing the space underneath the bed of the furnace work upon hinges, and are provided with ventilators by which air can be admitted to the pile to regulate the temperature. The sliding doors have small sight doors working on hinges. The carriage is moved by means of a chain, which may be worked by a steam engine, or other means. Double grated furnaces are employed, the bottoms of which are concave undermost, and convex at top. Each grate has a door working on hinges with a small ventilator in its middle to regulate the quantity of air entering the fire. The improvements in economizing the waste heat of the said furnaces consist in causing the said waste heat to heat one, two, or more longitudinal or vertical steam boilers, situated over or at the end of the furnace. The said boilers are supported on columns, and are provided with tubular flues through which the heated air from the furnace passes and heats the said boilers, and thence passes to the stacks or chimneys. *Patent completed.*

3385. E. Habel and E. Luckow. *Certain improvements in machinery or apparatus for preparing, spinning, and doubling cotton and other fibrous substances.* Dated December 18, 1862.

This invention consists in a novel and peculiar arrangement and construction of apparatus, which is equally applicable to spinning yarn, either in the form of cops or bobbins, and may be described as follows:—The spindle upon which the cop or bobbin is formed has a bearing in a footstep in a copping rail, and is supported at a higher point by a long bush terminating in a cylindrical case which encircles the spindle, and is sufficiently wide to admit the formation of a cop or bobbin within it, and is driven by a band passing round a pulley thereon. From the upper edge of this case a wire extends in the form of an arc or cone, and is provided with a peculiarly formed "oilet" at the apex, and others at convenient distances on the wire, by which means the yarn passes, and is spun directly from the drawing rollers to the cop or bobbin. The copping motion may be obtained by cams, as in the ordinary manner, or by means of a rotating disc having two studs acting upon a bell crank lever. In spinning cops, a long tube is employed on the spindle, which may either be furnished with a bottom plate and flannel washers to create the required drag, or it may be suspended upon the point of the spindle, and a spring employed acting on the surface of the cop to effect the pressure or drag, or a fan may be placed on the spindle for the same purpose. *Patent abandoned.*

3386. G. Russell. *Improvements in cranes.* Dated December 18, 1862.

This invention has for its object to construct a crane which, whilst it is of comparatively light and simple construction, shall be capable of covering a large area, or, in other words, of transferring a heavy load from any one point to another of a large area. In carrying out the invention, according to one modification, a jib, such as is commonly used in cranes, is combined with a short pillar or standard frame, which is either vertical or somewhat inclined, and from the top of which there proceed the usual adjusting chains or tension rods to the the upper or outer end of the jib. From the upper part of the pillar or standard frame there also proceed one or more tension rods, which is or are jointed to a pin or stud firmly secured in the ground or foundation. The lower part of the pillar or standard frame is connected to the fixed pin or c... triangular or other frame or frame piece serving ... The pillar or standard frame is mounted on a w... porting frame or carriage, or is arranged to slide ... or rails, or on a suitable surface in a circle round ... pin or stud, which thus forms a centre about ... crane may be moved. By connecting the pillar or ... frame in the manner described with a fixed poin... balance is dispensed with, and the jib can be made ... round a circle of much larger area than in other ... rangements, seeing that such area is what can be ... only by the radius of the jib merely, as measur... tally, but by that radius added to the distance of ... or standard frame from the fixed central pin or ... giving suitable inclinations and proportions to the ... to the standard frame or mast, or other subst... fore, the strain may be made to act in a vertical, ... vertical, direction upon the supporting frame ... in which case the horizontal strut between the ... carriage and the central fixture may be dispensed ... made of slight proportions. *Patent abandoned.*

3392. S. C. Lister. *Improvements in preparing, ... and spinning flax, silk, &c.* Dated December 18, 18...

The first of these improvements consists in pre... flax, rhea, and other vegetable fibres before comb... same upon drums or straps covered with fine teeth, ... less than 15 per square inch, but the patentee prefers ... the first operation, 100 for the second, and 200 for the ... time of passing it through the drums. Another par... invention—which is more particularly adapted for ... pierced cocoons, but which also answers well for pre... silk waste—is to make 2 straps of teeth to work ... gether; the cocoons or waste may be fed to them in ... suitable manner. The upper sheet should travel ... opposite direction to the lower. Another impro... consists in using drums for preparing silk waste (other ... cocoons) having more than 6 teeth to the square inch ... he prefers about 20 for preparing it the first time, ... to 100 for the second time over. Another impro... consists in using drums with teeth set much ... have been hitherto used for preparing silk waste ... patentee has discovered that pins standing out of the ... or other surface about half an inch, when very fine ... are used about quarter of an inch, will stand very ... with care will last a long time. Another of the im... ments in combing consists in making filling ... machines such as were patented by the present patentee

7th August, 1855, No. 1785, circled to the form of the :hine, and also having them constructed with gill or er teeth; or if the machine be straight, the filling heads r be made the same, but he prefers a circular machine. other improvement in such machines consists in in- sing the number of rows of teeth, as he finds that when ›ws only are used—as shown in the original patent—that fibrous material is apt to ruck at the back of teeth and ke more waste, and a worse sliver, than is the case when number of rows are increased. This can be readily done placing teeth in the front nipper, and increasing the nber of rows at the back of the back nipper. Another provement consists in making the filling heads of such chines as those patented by Lister and Warburton in 9, No. 2832 (under the first head of the said invention the said patent), to approach the comb, instead of having m stationary, as therein shown. The instrument which present patentee finds answer best is a filling head structed on Rawson's plan. The improvements in spin- g consists in giving a rubbing action to the rollers of a nning frame. The upper roller moves in one direction, ilst the lower moves on the contrary. The shafts upon ich the rollers are fixed have cranks attached to the end them, so as to give the required motion. *Patent completed.*

3393. A. V. Newton. *Improved apparatus for trans- tting power.* (A communication.) Dated December 18, 32.

This invention relates mainly to a novel arrangement or mbination of gearing applicable to the transmission of wer to steering, twisting, or hauling apparatus. The in- ntion may be described as consisting in the arrangement 2 cog wheels with a different or equal number of teeth, ie being firmly secured to the drum of a steering, twisting, hauling apparatus, and the other being stationary; or hen the apparatus is to be used for hoisting or other pur- ›ses, the former wheel being stationary, and the latter cured to the drum or drum shaft. In combination with iese cog wheels are pinions having an equal or different umber of teeth, and attached to a tumbling shaft which carried round the drum-shaft in such a manner that, on otating the wheel or drum shaft by the combined action f the two pinions on the tumbling shaft and the differen- ial wheels, a slow rotary motion is imparted to the drum or to the drum shaft when used for hoisting or other pur- oses). The power applied to the wheel shaft or to the umbling shaft is multiplied in proportion to the number f teeth of the gear wheel, which is fast to the drum, divided by the difference between the number of teeth of he said wheel and that of the stationary wheel, or, if the number of teeth of these cog wheels is equal, divided by he difference between the number of teeth of the two inions on the tumbling shaft, it being understood that a difference must exist either between the number of teeth of the cog wheels or of the pinions, or both. *Patent completed.*

3394. J. Holden. *Improvements in means or apparatus employed in preparing and combing wool and other fibres.* Dated December 18, 1962.

We cannot here devote space to the details of this in- vention. *Patent completed.*

3395. J. Holden. *Improvements in means or apparatus for washing wool and other fibres.* Dated December 18, 1862.

This invention relates to, when employing prongs, grates, or other surfaces adapted to conduct wool and other fibres through a trough of wash liquid for the washing thereof, effecting at the same time an intermittent for- ward and partial retrograde action to such means. For this purpose the prongs, grates, or other instruments may be applied to plates, bars, or carriers, which are controlled to move in irregular courses, or in courses with alternate progressive and retograde action, by which such instru- ments during their progressive motion will effect a forward and partial backward action to their points or operating ends upon the fibre. *Patent completed.*

3396. J. L. W. Thudichum. *Improvements in the pre- servation of beer and other fermented liquids, and in the apparatus and means to be employed therein.* Dated Decem- ber 18, 1862.

According to this invention, it is proposed to supply the cask or other vessel containing the liquid to be preserved with carbonic acid gas derived from any convenient source, such supply of gas being turned on at intervals, or each time a portion of the liquid is drawn off, the atmosphere at all times being excluded from the cask or vessel. *Patent abandoned.*

3397. W. S. Longridge. *Improvements in machinery for rolling tyres, hoops, and rings.* Dated December 19, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3398. E. B. Wilson. *Improvements in machinery or apparatus for forging and pressing metals and other sub- stances.* Dated December 19, 1862.

This invention consists in the use of a powerful lever actuated by a screw cam, steam, or hydraulic pressure, so as to produce either a constant or intermittent pressure upon the metal or other substances to be operated on, such substances being forged or pressed into any desired form by the aid of suitable dies situate under the lever before men- tioned. *Patent completed.*

3399. D. Davidson. *Improvements in the construction of telescopes, and in the method of arranging and fixing the same in combination with firearms for the purpose of adjust- ing the aim thereof.* Dated December 19, 1862.

This invention consists of certain improvements in the construction of telescopes, and in the arrangement thereof in combination with firearms, and supplies the require- ments in the method of taking aim consequent upon the improvements which have recently been made in the con- struction of the rifle and the great extension of its range. One part of the said invention consists of the following improvements in the construction of telescopes to be used in combination with firearms as before mentioned:—The field bar of the telescope is finished with two slides moving at right angles to each other, and worked by screws, each side carrying a cross hair or line, one of such lines thus being horizontal while the other is vertical. The hori- zontal line is for minute adjustment of the telescope in elevation, the vertical line being for allowance for side wind. The intersection of the lines when adjusted gives the aim. This improvement is applicable to the telescope, whether the latter be fixed to the rifle or other piece in the manner hereinafter described, or in any other manner. The other part of the said invention consists of improve- ments in arranging and fixing telescopes, of whatever kind, in combination with firearms, and is especially applicable to rifles and other small arms. The telescope is applied at the side of the piece, so that when depressed for the long range it clears the muzzle of the barrel. The body of the telescope is enclosed in a metallic tube, on which are fixed two collars, one at the object end of the telescope, and the other about 5 in. from the eye end thereof. The collar next the eye end is constructed with a neck furnished with square projections or lugs, the said neck entering a cor- responding hole in the escutcheon plate of one of the lock screws, the lugs taking hold of the inside of the plate on the collar being twisted. A joint is thus formed in which a sufficient amount of elevation or depression can be given to the telescope. The collar at the object end of the telescope is furnished with a quadrant, which latter presses against a plate of metal inserted into the stock of the piece at about 10 in., or at some other convenient distance, from the breech. A screw, furnished with a milled head, passes through the stock under the barrel, and through the before- mentioned plate of metal, and by means of a milled nut on the end of this screw (the head of which screw takes hold of the edge of the quadrant) the quadrant can be clamped securely at any required angle. *Patent completed.*

3400. A. V. Newton. *Improved machinery for attaching metal eyelets to cloth and other materials.* (A communica- tion.) Dated December 19, 1862.

This invention has for its object to facilitate the inser- tion of eyelets into fabrics and garments, and consists in the construction of a machine having a stationary punch or die, and below it a reciprocating bolster or die arranged in line with each other, together with a box for containing the eyelets, attached to which is an inclined shute down which the eyelets pass from the box to a position between the fixed and moveable dies. A reciprocating brush, mounted excentrically in the box, assists in the delivery of the eyelets into the shute, the openings through which the delivery takes place being of such form as to ensure the eyelets being delivered right side up. *Patent completed.*

3401. J. Dalton. *Improvements in knitting machinery.* Dated December 19, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3402. J. B. Morrison. *Improvements in washing machines.* (A communication.) Dated December 20, 1862.

This invention consists in the novel construction and arrangement of the parts of a washing machine, whose mode of operation closely resembles the hand process. This peculiar effect is produced by the employment of a corrugated or plain wash-board in connection with a yielding roller or rollers, or corrugated boards. The parts are so formed and combined as to secure cheapness of con- struction and convenience in operating the machine. *Patent completed.*

3403. F. W. Harvey. *Improvements in fitting and connecting rudders to ships and other floating vessels.* Dated December 20, 1862.

This invention is carried out as follows:—Along the edge of the stern-post of a ship the inventor forms a cir- cular shaped groove or channel, with a slit or opening along the same, and the bottom thereof he forms solid and circular; the said groove or channel is intended to receive the shaft of the rudder, which should be formed cylindrical and fit easily therein. He also forms an open- ing through the deck of the ship sufficiently large to re- ceive the rudder, which has simply to be lowered from the deck through the said opening, the shaft of the rudder being securely guided by and held in the grooved channel aforesaid; by these means the use of "pintels" and "gudgeons" at present used for connecting rudders to ships are entirely dispensed with. To the top of the rudder-post he connects a swivel cap, and the well-known right and left handed screw steering tackle; to that end of the screw of said tackle situate furthest aft, he connects a long pin vertically, the said pin passing through a hole in a standard fixed to the ship's deck, so that upon the rudder striking upon any substance, the rudder will be lifted, and with it the steering tackle and wheel, the long pin serving as the fulcrum for the tackle to move upon. Upon the obstruction being removed, the rudder and tackle will descend to their normal position by their own weight. He proposes to adapt tiller ropes to the shaft of the rudder in case of accident to the screw steering tackle, and to connect the same to an arm fixed on the rudder, the shaft serving also to indicate the true position of the feather of the rudder during the steering of the vessel. These improvements are especially adapted for iron ships. *Patent abandoned.*

3404. A. T. Blakely. *Improvements in breech-loading ordnance.* Dated December 20, 1862.

The object of the first part of these improvements is that the opening of the breech or separation of the breech-piece from the barrel may be effected by the act of firing, so that the firing of one charge will, in addition to throwing the projectile, open the parts and leave them in the position to receive a fresh charge. For this purpose the breech-piece projects into the barrel, and is retained in position by weight or elastic pressure proportionate to the power exerted by the pressure of the charge in firing. The firing causes the propulsion of the projectile, and at the same time the recoil of the breech-piece, thus opening the parts for the supply of a fresh charge. The breech-piece enters the barrel to an extent sufficient to ensure its not leaving the breech end thereof until the shot or shell passes out of the muzzle. Holding means retain the parts when opened. 2. The improvements relate to mounting ordnance to be fired through port-holes or embrasures, so that the axis of vertical motion is at or near the muzzle thereof, and at the port-holes or embrasures. As in this case the weight of the gun and its carriage will not, as is ordinarily the case, be balanced near the axis of rotation, and, consequently, great power will be required to move them, the patentee prefers to apply the power required by means of hydrostatic pres- sure exerted from a reservoir placed at a sufficient eleva- tion, or by hydraulic apparatus. *Patent completed.*

3405. J. Nettleton. *Improvements in stoves.* Dated December 20, 1862.

For the purposes of this invention, it is preferred that the external form of a stove should be cylindrical, though this is not essential. The interior of the stove, which is of iron, is lined with a hollow cylinder of fire-clay. Longi- tudinal air passages are formed up through the sides of such lining; or these air passages may be produced by having two linings of fire-clay with sufficient hollow spaces or passages between them to allow of fresh air passing through such passages from the bottom to the top of the stove without coming in contact with heated metal. In this part of the stove is an opening to receive fire-bars. The lower part of the stove, below the bottom grating of the fireplace, is enclosed, by which means a chamber is formed around and below the ashpit. The chamber at the bottom of the stove is arranged to communicate with the outer atmosphere by a suitable pipe or flue, by which pure air is introduced into the bottom chamber, which communicates with the air passages in the fire-clay lining by which the air thus introduced derives heat from the heating passages in the fire-clay linings. The heated air rises into an upper chamber of the stove above the fire-clay lining, and passes through numerous openings into the room; a sliding drawer is introduced into the ash-pit below the bottom grating of the fire-place. The upper end of the lining of fire-clay is covered with a fire-tile, and from it descends a fire-clay or metal partition which descends below the opening near the upper part of the stove where the products of combustion are conducted off by a suitable flue to the chimney. The air for supporting the combustion is supplied from the room in which the stove is placed, and such air is allowed to pass into the fire through the front fire-bars, also over the fire, and also by passing through suitable air-passages in front of the stove into the ashpit and up through the bottom grating of the fire-place. A valve or damper is applied to close, or partially close, the opening into the flue at the upper part of the stove. *Patent abandoned.*

3406. J. Michaelis and J. Rubino. *Improvements in the construction of locks, catches, or fastenings for purses, bags, or other receptacles.* (A communication.) Dated December 20, 1862.

Provisional protection has not been allowed for this in- vention.

3407. J. Cowpe. *Improvements in machinery for tearing, breaking up, and reducing rags, ropes, waste fabrics, and other similar fibrous materials.* Dated December 20, 1862.

This invention is an improvement upon the common "devil" hitherto used for the purposes above-mentioned, and consists in a new combination and arrangement of mechanism for the purpose—viz., an endless feeder upon which the material to be operated upon is fed between a pair of fluted rollers which deliver it to a rotating cylinder pro- vided with teeth. The journals of the fluted feed rollers are held in stands or brackets, which also hold a pressing roller placed in front of the fluted feeding rollers, and resting upon the roller carrying one end of the feeding apron; these stands or brackets also hold the bearings of a roller covered with card or other teeth, which roller is placed above the top fluted feeding roller, the bearings of the said toothed roller resting upon the journals of the top fluted feeding roller; the fluted feed roller is weighted by a lever at each side, which act upon the bearings of the toothed roller; the same weighting levers also act upon the pressing roller in front of the fluted feeding rollers. The toothed cylinder is rotated so that its teeth act upwards from the fluted feeding rollers, and the toothed rollers rotated so that the teeth when operating will move in the opposite direction to those on the toothed cylinder. Bends are placed on the side frames of the machine opposite the upper half of the toothed cylinder, which serve to carry the ends of a series of bars or "flats" passing across the cylinder from one bend to the other; these bars or flats are fixed at intervals apart from each other, and are provided on that side opposite the toothed cylinder with a series of teeth. These bars or flats are so arranged as to be readily adjusted so that the points of their teeth may be brought nearer to or further from the points of the teeth of the cylinder. The toothed cylinder is cased or covered both above and below. When the materials operated upon have passed the last toothed bar or flat which is furthest from the feeding rollers, it may be carried out through a suitable opening by the current of air produced by the rotation of the toothed cylinder, or it may be driven by the said cur- rent against a rotating wire cylinder, and thus pass out in sheets between the wire cylinder and a roller working against it. This invention further consists in causing the material after it has been taken over the toothed cylin- der to be carried back under the cylinder, and delivered in sheets by a rotating wire cylinder and roller placed under the feeding apron. *Patent abandoned.*

3408. A. V. Newton. *Improvements in the manufacture of automatic toy figures.* (A communication.) Dated December 20, 1862.

The object of this invention is to impart to toy figures a natural walking or stepping movement, in lieu of that heretofore obtained by the use of wheels or rollers. This object is effected by the employment of a peculiar arrange- ment of double eccentric cam joints in connection with vertical or upright levers and pedal supports, whereby, through the medium of suitable clock mechanism, such reciprocating and alternating clock movements may be

given to the pedal extremities of the figure as will ensure the propulsion of the figure along a tolerably even surface. *Patent completed.*

3409. J. PLATT and RICHARDSON. *Improvements in scutchers or beaters of cotton, machinery applicable also to other machinery in which shafts are caused to revolve at high velocities.* Dated December 20, 1862.

This invention relates to a method of keeping the shafts of beaters or scutchers, or other rapidly-revolving shafts, cool; and for this purpose the patentees form the said shafts hollow and place water therein. *Patent completed.*

3410. W. PERKINS. *Improvements in the manufacture of a substitute for turpentine, which is also applicable to the manufacture of varnishes and to purposes to which turpentine is now ordinarily applied.* Dated December 20, 1862.

The inventor proposes to effect the purification of amyle or fusil oil, or of the oxides of amyle, by means of hypochloride of calcium, chromic acid, sulphuric acid, or any mixture of them in about equal proportions, and afterwards to effect the rectification or distillation of the same at a temperature of not less than 270 deg. Fahr. upon such bodies. He afterwards proposes to make an admixture of the aforesaid amyles with their equivalent proportions of liquid hydro-carbons from whatever source obtained. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated April 28, 1863.

1067. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in apparatus for preserving property in case of shipwreck. (A communication.)

Dated May 7, 1863.

1146. C. A. Day, A. Lamb, and T. Summers, Southampton, engineers. Improvements in marine engines.

Dated June 12, 1863.

1475. J. F. Toue, Newcastle-upon-Tyne, civil engineer. Improvements in the prevention of smoke in steam boilers and other furnaces. (A communication.)

Dated June 13, 1863.

1482. R. Blackburn, Exeter, engineer. Improvements in traction engines.

1485. J. S. Benson, merchant, and D. Jones, manufacturer, Birmingham. An improved construction of removeable head for casks, applicable to the closing of other vessels.

Dated June 15, 1863.

1498. R. W. Gordon, Belfast. Improvements in machinery for spinning flax and other fibrous substances.

Dated June 17, 1863.

1520. E. Wolf, Sambrook-court, Basinghall-street, merchant. A new or improved wrapper or wrapping material for use in smoking tobacco.

Dated June 18, 1863.

1525. J. L. Ganne, Cour Cheverny, France, engineer. Improvements in toy pistols.

1527. D. Barker, Milton-street, Wandsworth-road, corn merchant. Improvements in the treatment and preservation of yeast.

1529. E. Ivett, Bedford, brick and tile manufacturer. Improved machinery for the manufacture of tiles.

1531. E. Gossiaux, Laeken, Brussels, manufacturer. An improved machine for making bolts, rivets, and spikes.

Dated June 19, 1863.

1533. E. Howarth, cotton spinner, and J. Brown, machinist, Tonge, near Middleton, Lancaster. Certain improvements in apparatus for steaming cotton or other fibrous substances.

1535. R. Marrison, Great Oxford-street, Norwich, gun manufacturer. Improvements in breech-loading firearms.

1537. A. Morel, Roubaix, France, manufacturer. Improvements in machinery for combing wool and other fibrous material.

1539. J. Watts, Coventry, accountant clerk. Improvements in machinery or apparatus for the manufacture of malt.

1541. W. E. Newton, 66, Chancery-lane, civil engineer Improvements in the manufacture of leaden pipes. (A communication.)

Dated June 20, 1863.

1543. T. Smith, Tenter-lane, Leeds, millwright, T. Moore, Upper Mills, Wandsworth, and Major Murrell, King's Mills, Leeds, corn millers. Certain improvements in the construction of reels covered with silk or other suitable material used as machines for the purpose of dressing flour.

1545. D. D. Kyle, Victoria-street, Westminster. An improvement in baths.

1547. R. Brownlee, Glasgow, saw miller. Improvements in sawing machinery.

1551. J. L. Clarke, 45, Westbourne-terrace, Hyde-park. Improvements in apparatus for turning over the leaves of music and other books.

1553. F. Jenkin, Duke-street, Adelphi. An electric telltale compass.

1555. W. L. and T. Winans, Baltimore, United States, gentlemen. Improvements in the construction of steam vessels.

1557. W. L. and T. Winans, Baltimore, United States, gentlemen. Improvements in adapting propellers for propelling ships or vessels for ocean navigation.

Dated June 22, 1863.

1566. F. Boult, Liverpool, merchant. An improved method or process for obtaining patterns and designs for the arts and manufactures. (A communication.)

Dated July 1, 1863.

1636. T. Boyle, 31, Gray's-inn-road, lighting and ventilating engineer. An improved system of ventilation applicable to every description of dwelling place and building.

Dated July 2, 1863.

1646. R. A. Brooman, 166, Fleet-street, patent agent. Certain compositions for protecting metals and metallic articles from oxidation, and for coating slate, bricks, pottery, and ceramic wares. (A communication.)

1648. E. Lloyd, 22, Wells-street, St. Marylebone. An improved composition for waterproofing, softening, and preserving all kinds of leather and articles made therefrom.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated July 8, 1863.

1701. G. Haseltine, 12, Southampton-buildings, Chancery-lane. Improvements in lever horse-power machines, the cog-gearing employed being applicable to other machines. (A communication.)

Dated July 13, 1863.

1752. H. A. Bonneville, 24, Rue du Mont Thabor, Paris, patent agent. Improvements in certain descriptions of breech-loading firearms. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, July 21, 1863.

629. J. Elsey. Winding of lace on to the work roller in warp lace, bobbin net, or twist lace machines.

640. T. Hancock. Receptacle for coins.

663. R. T. and R. Monteith. Making dyes from aniline and its analogues. (A communication.)

663. J. Cassell. Lamps. (A communication.)

666. H. Wilson. Machinery for shaping wood.

670. J. Werge. Indicating any regulated maximum or minimum degree of temperature. (A communication.)

671. J. Tomlinson. Machinery for opening twisted yarns and woven fabrics.

675. H. D. and J. W. Taylor. Finishing fabrics.

692. J. Page. Taps or valves.

695. R. Alexander. Mariners' compasses.

699. J. Walworth. Washing or cleansing and drying Egyptian wheat.

723. R. A. Brooman. Manufacture of spoons and forks. (A communication.)

724. F. and J. G. Richmond and H. Chandler. Washing vegetables.

727. B. Wren. Cleansing and treating certain descriptions of grain.

735. E. Lover. Composition for the coating and preservation of canvas and other materials.

745. J. and T. A. Nield. Core barrels.

746. R. A. Brooman. Beating and drying wool and other textile and filamentous substances. (A communication.)

795. G. Davies. Engraving upon metals. (A communication.)

885. J. N. Brown. Securing or connecting the bearing springs of railway carriages and waggons to the axle-boxes of the said carriages and waggons.

1070. R. Butterworth. Carding engines.

1212. A. Pilbeam. Sewing machines.

1269. G. R. Harding. Transmitting power on railways.

1390. J. J. McComb. Construction of presses for forming bales of cotton and other materials. (A communication.)

1447. W. Clark. Locomotive apparatus. (A communication.)

1513. W. H. Dawes. Manufacture of iron.

1574. C. T. Burgess. Reaping machines.

2602. R. Mushet. Manufacture of iron and steel.

1701. G. Haseltine. Lever horse-power machines. (A communication.)

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed July 17, 1863.

145. L. Verdure.	222. A. J. Sax.
177. J. W. Mears.	226. W. F. Stanley.
178. A. Phillips.	232. H. H. Henson.
192. H. Caro and J. Dale.	243. H. B. Barlow.
198. J. M. Binger.	260. H. Crichley.
206. J. Milner.	274. W. Clark.
210. F. N. Gisborne.	791. N. R. Hall.

Sealed July 21, 1863.

11. J. E. Baker and J. Landon.	342. J. Cameron.
209. C. Stopford.	400. W. C. Paul and A. T. Shore.
223. R. A. Brooman.	480. H. Mackinder.
237. W. Rollason, jun.	667. W. Wood.
239. J. Edmondson and T. Ingram.	786. G. F. Key.
241. D. E. Hughes.	929. R. Reeves.
261. B. J'A. Bromwich.	1251. J. H. Johnson.
273. G. Blake.	1256. A. Parker.
	1418. G. W. E. Friederich.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

1701. S. C. Lister.	1779. G. H. Birkbeck.
1726. J. Fletcher.	1769. J. H. Young.
1730. A. C. Bamlett.	1772. M. A. F. Mennons.
1731. E. Loysel.	1810. T. and De G. Fowler.
1750. A. B. Woodcock.	1816. A. Gélis.
1754. J. Saxby.	
1764. C. C. J. Guffroy.	

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

1661. W. Watt.	1674. T. Duncan.
1670. H. Turner.	1725. J. E. Hodges.

LONDON, FRIDAY, JULY 31, 1863.

THE BHORE GHAUT INCLINE.

A SLIGHT acquaintance with physical geo-raphy, is sufficient to inform us that very nany of the largest mountain chains, found in oth the Old World and the New, run parallel o the sea-shore at comparatively trifling dis-ances from those littoral regions, whose princi-al towns being seaports, act as the gates of vealth to the country at large.

Such is the character of the immense vol-anic range known as the Western Ghauts of ndia. Extending from Cape Comorin in the outh, almost to Surat in the north, over a dis-ance of nearly one thousand miles, it affords xamples of the most magnificent scenery in ne known world; while, savage, gloomy, nd inhospitable, it has for centuries, proved n almost inaccessible barrier to the develop-nent of the natural resources of the vast terri-ory which it effectually cuts off from all ommunication with the sea; all the benefits f commerce having been confined to a tract f country varying from 30 to 100 miles wide hich separates it from the coast.

Facilities for transport almost invariably rove the measure of the prosperity of a nation. Neither ancient history, nor modern statistics, ipply us with any exception to this rule. ncient Rome, modern England, alike owed nd owe their prosperity, and their might, to nat vast world of waters which offers a path the ends of the earth, and to those magni-cent roads which, penetrating the Continent in very direction, found a common centre in the etropolis of the world.

The enlightened Englishman of the 19th entury was not slow to perceive the advan-ages which proper means of transport would estow on our enormous East Indian posses-ons, and the extension of the railway system that country was early proposed. Its adop-on there, quickly placed in a most important ght the difficulties to free communication ith Bombay, occasioned by the Western hauts, or, to term them by their proper name, e Syhadree Mountains. The general cha-acter of this range is that of an abrupt volcanic carp, the height of the lowest part of the argin of which is about 2,100 ft. above the evel of the sea. From the line of its main irection various spurs project westwards into e Concan, and eastwards into the vast plain f the Deccan, which slopes gently to the other de of the peninsula. These spurs or ghauts orm inclined plains, descending from the ummit of the range by degrees—some-mes gradual, sometimes precipitous—until ey become lost in the level country elow. Little reflection is needed to show e serious injury to commerce caused y a natural obstruction to communication be-ween the interior of the country and the towns n the sea-coast. Steep and precipitous to a egree, the main body of the hills are practi-ally inaccessible, the only feasible places for n ascent being found in the spurs we have just entioned. For a distance of 220 miles, they re unsurmounted by any important path save e Agra road up the Thull Ghaut, and the oona and Calcutta road up the Bhore Ghaut. Were it not for these, Bombay would be cut off om direct communication with the interior. e track up the Bhore Ghaut is little more han a mountain pass, scarcely available for el carriages, travellers requiring two days, goods three, to traverse a distance of 48 miles. The Thull Ghaut road is somewhat better, but, even after a considerable outlay of money and engineering skill, it is still quite inadequate to meet the demands made on it by the traffic of the country. Besides these, there are a multitude of foot-paths and steep bullock-tracks, utterly worthless in a general sense, or at best, only capable of affording a means of local communication of the most insignificant value.

The magnitude of the interests involved is so great, and so thoroughly understood in commercial circles, that it requires no illustration at our hands. It is not, perhaps, too much to say that the benefits of such means of transit over these hills, between Bombay and the Deccan, as only a railway can afford, would not have been dear, had they been purchased at ten times the expenditure which the construction of the Bhore Ghaut railway incline has required. It is in many years hence that the vast benefits conferred by this line will be realized. The resources of the country which it opens up cannot be estimated, because we can but surmise the effects on its trade, which will be produced by good roads, railways, docks, harbours, and, in short, those magnificent works of civil engineering in which India is so deficient, though they are indispensable to her prosperity.

The first decided step towards the formation of a system of railways in India was taken by our Government in 1849. The Great Indian Peninsular Railway Company sprang into existence about the same time; and nearly the first proceeding undertaken by their engineers on their arrival at Bombay in 1850, was an examination of the different Ghauts within moderate distances of that city, which seemed most suitable for the construction of a railway over the Syhadree Hills. The Malsej Ghaut first claimed their attention; but a little examination showed that a route in this direction presented difficulties which, being almost insurmountable, led to its abandonment. The Bhore Ghaut was then the subject of a careful survey. This long spur, projecting a considerable distance into the plain, and rising by a comparatively easy gradient, possessed advantages which the closest examination failed to discover in other Ghauts.

The first result of a somewhat hasty decision was the laying out of a line, the length of which was about 13½ miles, with a total rise of 1,796 ft., or about 133 ft. to the mile, its cost being estimated at £483,900, the most objectionable feature being a stationary engine plane rising 1 in 20, and 1¼ miles long. Further operations, however, fortunately demonstrated that this might be avoided, by laying out a continuous locomotive gradient from the base to the summit of the Ghaut. The magnitude of the work, however, alarmed Lord Dalhousie, the Government being the guarantors for the necessary capital. A still more extensive and careful survey of the Syhadree range was determined on, and executed during the year 1853. Twelve Ghauts were surveyed, with a result which is best expressed in the report made by the late Mr. Berkley, chief engineer of the line at that time:—"For the purpose of laying out the South Eastern Line, I have now examined the Syhadree range, between the Malsej and the Sewta Ghauts, between the Deccan valleys of the Mokree and Neera; and upon the Concan, from the River Kaloo to the River Savitree (a range of 80 miles); and I certify that, to the best of my professional judgment, the Syhadree Mountains afford no place of ascent so eligible for the South-Eastern Railway as the Bhore Ghaut."

Although no better route could be discovered, yet the time expended on these surveys could not be considered thrown away. Mature reflection, and, perhaps, the experience gained by the explorers, led to a great improvement in the proposed line, which was again altered with the effect of flattening many of the gradients from 1 in 35, to 1 in 40 and 1 in 50; at the same time reducing many of the works to moderate dimensions. Subsequently, the reversing stations—one of which has since been adopted with great advantage—were proposed, other slight alterations in the route were determined on, which raised the level of the line where it encountered the heaviest ground, permitted the establishment of a station at Kandalla, and, in short, effected so many improvements, that its construction was at once entered on; a very few alterations being introduced during the progress of the work. The Bhore Ghaut, as now constructed, is 15¾ miles long; the level of the rails at its base is 195 ft. above the sea, and at its summit 2,027 ft., so that the total elevation surmounted by this incline in one long lift is 1,832 ft. Its average gradient is consequently 1 in 46·39, including the reversing station.

The works were commenced about the month of January, 1856, having been let by contract in the autumn of 1855, to Mr. Faviell; the constructive details being placed under the local superintendence of Messrs. Adamson and Clowser.

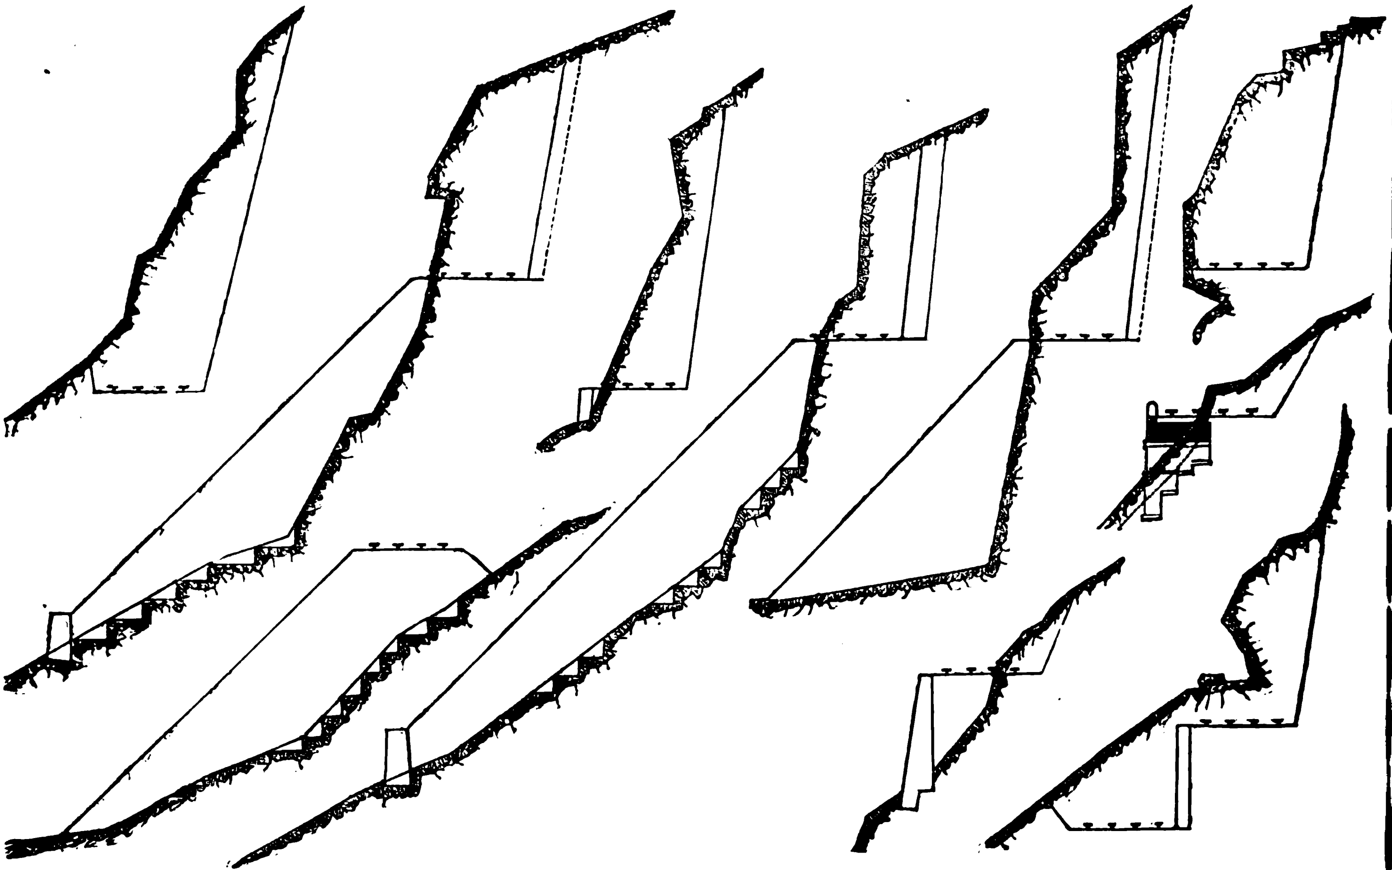
On the 14th January, 1858, the first portion of the incline (from the summit at Lanowlee to the station at Khandalla, a distance of 2¼ miles) was opened for traffic. Beyond the severity of the gradients, and a heavier amount of earthwork than usual—54,000 cubic yards of excavation being hard rock—there is nothing remarkable about this section.

In March, 1859, Mr. Faviell, from circumstances which it is not necessary to particularize, but which were chiefly brought about by the high price of labour, relinquished his contract. The amount spent up to that time was £210,000; but though much of the surface work had been done, the most formidable parts of the undertaking—the lofty viaducts, the tunnels, and the heavy cuttings through rock—were hardly commenced. The works were, however, carried on by the Railway Company's own engineers, Messrs. Adamson and Clowser, until the following November; when Mr. Solomon Tredwell, to whom the contract had in the meanwhile been re-let, commenced operations on a scale commensurate with the magnitude of the undertaking.

On the 15th of March, this gentleman entered on the works; only fifteen days afterwards, however, we regret to say, he was attacked by alarming sickness and died. His character and talents are well known; he was one of the most active and able contractors in England, and his decease was felt to be a public calamity.

Had it not been for the spirit and judgment displayed by Mrs. Tredwell, who in the midst of her affliction courageously entered on the contract, there is no saying how long the works might have been retarded. Misfortune followed misfortune. A little more than a month later, cholera broke out on the lower part of the Ghaut, and of 10,000 labourers employed on the first seven miles, only 1,000 were left after a fortnight had elapsed. Of the rest, many had been carried off by the disease; most had fled from fear of it. In February, the cholera subsided, and the effects of the visitation were being overcome, when it returned with redoubled violence in March. This time it prevailed throughout the whole length of the incline, and the progress of the wor almost stopped for the remainder of t

CROSS SECTIONS OF THE BHORE GHAUT INCLINE, OF THE GREAT INDIA PENINSULA RAILWAY.



Under these circumstances it was proposed to secure the services of Messrs. Adamson and Clowser, who had been the Company's resident engineers on this part of the incline from its commencement; and who, by a careful and liberal management during the time they had been carrying on the works for the railway company, had induced the labouring classes to look with favour upon the locality, and had overcome that previous scarcity of work-people which was the chief impediment to an efficient progress. A measure which was calculated to ensure the speediest completion of the incline, was also best calculated to promote the interests of the railway company; and with the permission of the directors, under the advice of the chief engineer, Mr. Berkley, they consented to take the management of the contract, and Messrs. West and Tate were appointed the resident engineers on the part of the railway company. Including these changes and several delays, the whole time occupied in the construction of this vast work has been about 7¼ years, under three distinct agencies at various times—under Mr. Faviell's contract for 3¼ years; by the railway company for 7½ months; and under Mr. Tredwell's contract (represented by Messrs. Adamson and Clowser) for nearly 3¼ years.

It is difficult for the engineer who has no experience of the system of railway work in India, to estimate the real difficulties encountered in constructing a first-class double line, specially intended for the heaviest traffic, up the side of a mountain, covered with dense jungle in many places; in others, encumbered with huge boulders resting on a soil swampy and treacherous to the last degree. The English engineer accustomed to the control of a well-organized army of "navvies," trained to work together with an almost military discipline, can form but a poor idea of the East Indian railway labourer carrying a few shovels-ful of earth in a basket on his head. Thus we learn from an able little pamphlet by Mr. West, C.E., which has afforded us much of the valuable information we lay before our readers, that the wheelbarrow, the most useful of all the machines employed in the construction of a railway, has scarcely been used; the greater part of the earthwork, having been basketed or carried by the native workmen. In order to give some idea of the magnitude of the works executed by such an apparently feeble agency, we give above a few cross sections of different portions of the line. Numbers and skilful direction compensated for any lack of individual power; and thus the history of the undertaking, is a record of a constant triumph over difficulties and dangers, which entitles the Bhore Ghaut Incline to rank as one of the most magnificent works ever executed by the ancient or modern engineer; and this, be it remembered, at a cost moderate in the extreme, when we compare the advantages gained, with the outlay to obtain them. Much valuable information is embraced in the following summary, from the pen of Lieutenant Swiney, Royal Engineers:—

"At the close of the working season of 1860, £123,000 had been expended by the contractors, making a total of about £350,000. During the same year the maximum number of workmen was 77 Europeans and 18,676 natives.

"The progress in the Bhore Ghaut during the following working season was quite unprecedented; owing to the excellent arrangements made by Messrs. Clowser and Adamson, even so early as October, 18,000 work-people had been collected. In November, there were 30,000; in December and January, 42,000; as much as £46,000 being expended per month in wages. By May, 1861, all the tunnels were in a forward state, and the progress in the viaducts and rock-cuttings was most satisfactory; and the engineers were able to speak with confidence as to the date of the completion of the work.

"The total expenditure then amounted to £600,000.

"During the following working season, the average number of workpeople employed on the Incline was about 25,000, the maximum number being 33,000 in January, 1862.

"The expenditure during this season was above £240,000; and the chief resident engineer reported in September, 1862, that there was every reason to expect that, by the end of March, 1863, the Incline would be opened for public traffic. This expectation has been realized almost to a day."

To enter into a detail of all the engineering difficulties encountered in the construction of this line would fill ten times the space we can devote to the subject, and we must content ourselves with a mention of one or two of the most important works executed.

In the original design were embraced 12 tunnels, their entire length forming 2,532 yards; 14 additional tunnels, making a further distance of 1,325 yards were substituted for cuttings during the progress of the work, in situations where the treacherous nature of the ground rendered the standing of the slopes doubtful. In some cases, the excessive hardness of the rocks rendered the operation of tunneling very slow; in others, a mixture of boulders, through earth otherwise moderately soft, rendered a masonry lining with all its attendant evils absolutely indispensable. Added to this in only two places were shafts practicable or advisable.

The viaducts are built of solid block-course masonry, up to the surface of ground, and above that of block-in-course

work, strongly tied to the internal work of sound rubble; all the arches are built of squared stone laid in courses, with ashlar arch quoins; not a brick has been used in any of the works on the contract.

At the village of Khandalla, the railway passes across an angle of the Tank, its formation level, 15 ft. below the highest level of the water. As the village and the Ghaut traffic, as well as the railway works are dependent upon this tank alone, for a supply of water, it was necessary to cut off the angle of the tank by a water-tight retaining wall 490 ft. in length, parallel with the railway line. By waiting until the level of the water had become low in the hot season, nearly half the length was built without much difficulty from the water; but for the remaining length of 270 ft. it was necessary to incur the expense of a coffer-dam. It was built in four lengths, the foundation averaging 10 ft. below the surface of the water when at its lowest level.

The lime used near Khandalla was brought from the Deccan, from distances of 20 to 40 miles. For the lower part of the Incline, lime from Bombay was used. Much of the sand had to be brought from distances varying from 4 to 10 miles.

The small springs which are to be met with occasionally, within a short distance of the railway, were not sufficient even to afford drinking water for the work-people in the hot season. For the centre and much of the lower part of the Incline, water for general purposes and for the masonry was brought up from the Oolassa on bullocks, a distance of 4 or 5 miles. The upper part of the Incline was supplied in the same way from Khandalla, and for a similar distance. By damming up one of the tunnels before the rains, it was converted into a reservoir, which afforded an ample supply of water during the following season, for the works in its neighbourhood. Pipes were also laid down, which considerably shortened the distance of carriage from Khandalla. It was necessary, however, to keep 1,500 bullocks constantly employed in the carriage of water alone, when the works were in full progress.

About 16 miles of cart road, and more than double that length of bridle and bullock paths, had to be constructed to give access to the works. A railway siding of nearly 2 miles in length, from Telowlee Station to Wonee, was also laid for the purpose of bringing up materials.

The reversing station is simply a means by which the direct ascent of the hill side is changed into one much longer and more gradual. It is so called because the engines being turned there, the tail of each train becomes the head during the remainder of its progress, and the train leaves the station in the same direction in which it entered it, but on a different level. At this station there is a very remarkable viaduct, the roadway being forked like the letter Y. The two diverging lines being inclined at different levels, while that part of the line represented by the tail of the Y is at the same level for both lines.

The gradients of the Bhore Ghaut Incline, which are all ascending, are as follows:—

	Miles.	Chains.
1 in 37	1	38·51
1 in 40	8	4·85
1 in 42	1	11·36
1 in 43·164	0	30·83
1 in 50	2	50·12
1 in 50·08	0	39·15
1 in 75	0	27·45
1 in 880	0	23·00
Level	0	75·74
Ditto, at the Reversing Station	0	20·50

The curves vary from a radius of 15 to 80 chains, an aggregate length of over four miles being straight. A comparison between this and the two most remarkable mountain inclines in Europe cannot fail to prove interesting.

The Giovi Incline, on the Turin and Genoa railroad, is 6 miles long, rising in that distance 889 ft., with an average gradient of 1 in 36, the steepest being 1 in 29; the sharpest curves being 20 chains radius. The Semmering Incline upon the Vienna and Trieste Railway has no less than 30 curves of 10 chains radius, with an ascent from Payerbach to Semmering, of 13¼ miles, rising in that distance 1,325 ft., with an average gradient of 1 in 47, and a descent from Semmering to Murzzuschlag of 8¼ miles, falling 705 ft., with an average gradient of 1 in 50.

The Bhore Ghaut Incline, with a total length of 15¾ miles, rises 1,831 ft., with an average gradient of 1 in 48, the steepest being 1 in 37. The above particulars are derived from a paper read before the Bombay Mechanics' Institute by its President, the late Mr. J. Berkley, C.E., in December, 1857.

The earthwork in cuttings and embankments amounts to 4½ millions of cubic yards.

Several of the embankments exceed 60 ft. in height, and many of the outer slopes are 150 ft. in length, and some of them as much as 300 ft. The greatest depth in the centre line of cuttings is 74 ft., and in one cutting the excavation on the upper side is nearly 150 ft. deep through solid rock!

On the 30th of March, 1863, seven years and three months after the beginning of the works, an experimental train, consisting of two Ghaut engines and their brake vans, were run through for the first time, running 13¼ miles, from Padusdherre to Khandalla in 52 minutes. The engines with which it is intended to work the Incline are fourteen in number, worked in pairs, by coupling them back to back; they are without tenders, carrying the water tanks on their own frames. Their principal dimensions are as follows:—Diameter of cylinder, 15 in.; length of stroke, 22 in. Each engine has two pairs of wheels, of 4 ft. diameter, coupled. Each engine has 160 tubes, of 2 in. outside diameter. The heating surface is equal to 1,055 sq. ft., of which 980 sq. ft. are in the tubes, 75 sq. ft. in the fire-box. Each tank contains 800 gallons. There is a skid-brake between the wheels on both rails. The total weight of an engine, when in working order, is about 34½ tons.

We have already given a notice of the opening of the Incline, on Wednesday, the 21st of last April; since then the regular traffic has been conducted with the greatest success, and, from the permanent character of all the work, there is every probability that it will so continue for a very long series of years, with an extremely moderate outlay on repairs.

It is worthy of note that this, the greatest railway work ever executed by English capital or enterprize, can scarcely be said to have been constructed for military reasons. Although it permits the despatch of armies to almost any part of the peninsula, this was regarded as a very secondary advantage by its promoters; and we trust that a long reign of peace may aid us to forget that it is applicable to such a purpose. A proposal was once laid before Alexander the Great for the construction of a colossal statue, to be hewn out of a mountain, on such a scale, that while one outstretched hand supported a city, the other should pour forth a river to water the plain below. The magnitude of such a work could only equal its absurdity. We more wisely hew mountains, not into statues, it is true, but, nevertheless, into memorials which, enduring for ages, will cease not to sustain cities and pour forth rivers of wealth on nations; such a record is presented in the passage of the Syhadree Mountains by the Great Indian Peninsular Railway.

MANUFACTURING MACHINERY WITH PROFIT.

It requires but a few minutes' walk through a mechanical workshop to fully comprehend that to make money by manufacturing engines or machinery, requires a combination of gifts and acquirements of no ordinary character. The prosperous management of such an undertaking calls for natural inventiveness, scientific ability, practical workshop knowledge, and commercial tact; these must be a combination of the inventor, the man of science, the workman, and the merchant at the head of the concern. To design the work always requires great scientific and practical knowledge, and sometimes high inventive ability. To turn the work out well and cheaply, a long apprenticeship in the shops is absolutely needed; while to get profitable orders in the face of rival competition, demands the mercantile shrewdness and smoothness of the practised salesman. Such a union of natural and acquired gifts has been seldom or never met with in one person. No wonder, therefore, that the number of those who have realized large fortunes by engine manufacturing can be counted on one's fingers. To make rails, pins, buttons, or bottles; to spin, weave, or print cotton, and to make these operations pay, requires little else besides commercial ability. The few profitable engineering undertakings have been those like Boulton and Watt's; where the commercial faculties of a Boulton worked in harmonious union with the scientific genius of a Watt.

Perhaps no great enterprize—and the successful management of an engineering manufactory is undoubtedly one of this character—can be conducted successfully without the application of the great principle of the division of labour. In the words of Adam Smith, "the greatest improvement in the productive powers of labour, and the greater part of the skill, dexterity, and judgment, with which it is anywhere directed or applied, seem to have been the effects of the division of labour." This principle may be said to take the same rank in Political Economy as the Inductive Method in Physical Science. Both principles have been always more or less instinctively practised by mankind; but such intellects as those of Adam Smith and Francis Bacon were required to elaborate and distinctly enunciate their complete significance.

In these times of sharp competition, however, a division of labour in the management is not all that is required. We thus find that the really prosperous firms are those fortunate enough, or skilful enough, to also confine their trade in a special direction. It has been well observed that the happiest nations are those with the dullest histories. In the same way, the most fortunate engineering undertakings are those with the dullest practice; variety may be charming, but it is not always profitable, especially when it takes the shape of weekly wages to draughtsmen and pattern-makers. The maker who is able to confine his practice to special work, assimilates his position to that of a button manufacturer. There are few calls on him for expensive new experiments and designs; the interest and novelty of the work diminish, but his profits proportionately increase.

The first effect of narrowing the circle of variety in an engineering establishment is evidently to diminish the cost of getting out the estimates for tendering, and the book-

keeping expenses generally. Fewer drawings are then required, with their resulting new patterns and templets; all three most expensive items, and always locking up a large amount of capital. In shops doing a variety of work, a number of special foremen are required at the head of the different departments; a want unfelt when the work repeats itself day by day. The capital saved in such a way can be expended on special tools and machines; and the judicious use of these will alone often economize large sums for the proprietors. It is astonishing how far the use of special tools may be carried where there is a repetition of work. The different details can be accurately turned, bored, and tapped to special brackets constructed for the purpose, and the saving in quantity and quality of work by these means is very great. It is only by the use of these apparatus that the same class of engines or machines can be made exact counterparts of each other; thereby greatly cheapening and facilitating the repairs at any future time. The usual result of the division of labour is also seen in the great increase of dexterity in every particular workman; an effect which shows itself very forcibly by enabling a gradual reduction of the piece-work prices for different jobs. Another enormous economy—accelerating the operations of the whole establishment—is that of the saving of time "usually lost in passing from one species of work to another." There is even a division of the labour of the individual; and the difference between a good workman and a bad one is not always mere manual strength or dexterity, but rather a more or less complete recognition and adaptation of the division of labour principle.

To the adoption of this system, the great prosperity of the well-known works of Messrs. Platt Brothers, of Oldham, is greatly due. Before the unfortunate lull in the cotton trade, caused by the American war, nearly 5,000 men were there employed in manufacturing cotton machinery. Few managers are required at these works, but they receive a proportionately larger salary. The men—employed constantly on piece-work—were enabled to earn large wages, with profit to their employers. Machine labourers, at 15s. and 16s. a week, could do the work of 30s. turners and fitters at the special tools. The greater part of the work in the foundry is also done by special moulding machinery.

The well-known works of Clayton and Shuttleworth, of Lincoln, which are confined almost entirely to the manufacture of portable and fixed agricultural engines and thrashing machines, are managed on the same principles. The Gorton Foundry, near Manchester, conducted by Mr. C. F. Beyer, for many years the manager of the Atlas Works, Manchester, is considered a model establishment in every respect—management, system, and work turned out. Little else than locomotives, and tools for manufacturing that class of engines, are made at these works; and perhaps no other workshops can be cited as having acquired so high a standing within such a short period.

Now that many branches of mechanical engineering are getting consolidated in form, and are becoming, to a certain extent, less susceptible of alteration and improvement—*e.g.*, cotton machinery—there is an imperative necessity for any firm wishing to play a large part, to concentrate its trade as much as possible. The houses that fail to do this, will be inevitably distanced by their fellow competitors. Several shops in Lancashire, where locomotives were manufactured a few years ago, have been driven out of this market by the establishments specially organized for this class of work.

If, from a short-sighted greed of gain, orders of an uncommon description be accepted for which even a fancy price be given; even if they bring in a large *direct* profit; nevertheless, by their uncommon character, the profit on the usual work of the shop is lessened, from the derangement of the ordinary course of proceedings. Losses of this description can be ascertained with difficulty—if at all—from the books; while they are often much greater than is imagined by some people. Just as the vast extension of human knowledge has rendered a modern Admirable Crichton an impossibility; just as professional success in the individual imperatively requires the elaboration and adoption of some speciality; so also is it impossible for an engineering establishment to succeed in a variety of things; while the delivery of a second-rate article will often injuriously affect the sale of other manufactures in which the same firm may even happen to excel all others.

At the same time, a narrow range of articles manufactured in any establishment, has a tendency to contract the ideas of the managers; an effect which often conspicuously shows itself when any arrangement be undertaken out of the ordinary line. The pupils and apprentices have also a better chance of learning their business in shops where multifarious kinds of work are executed. Again, there is a danger in executing everything by "piece-work;" a plan to be only fully carried out when there is little variety in the work done. The men are continually tempted to "scamp" their work, and quality is not always obtained in union with quantity. Nevertheless, payments by the piece are the only means of "paying by results" in a workshop—in all cases and situations the most equitable and profitable for both employer and *employé*. As a rule, with "daywork" the *men* have to be looked after, in order to obtain quantity; with "piecework" the *work* itself has to be strictly inspected, that quality may not lag behind. The safest plan when machines are manufactured by "piecework," is to submit them to a thorough practical test; to put them—while still in the hands of the erectors—to the work they are intended to perform when delivered.

It sometimes happens that a firm of long standing in the engineering trade finds itself greatly committed to a variety of work; and other firms, starting later, and thus unfettered in the many ways in which an old establishment is bound, often get the start in special descriptions of machinery. This might, perhaps, be met by a regularly organized system of giving out any unusual orders on commission or in exchange for others of a more suitable description. This plan is carried out by several eminent firms in Lancashire. Some of these establishments also derive a regular trade in designs by selling, at a high price, sets of tracings of any engines or machines that happen to have been completely drawn out on paper. An old firm could often get a profit in this way out of many of the patterns and designs that would otherwise uselessly depreciate by age, and by the continual progress in all things mechanical. With a proper contract, carried out by a strict inspection, as good—or even better, and most certainly cheaper—work could be delivered if the sub-contractors be properly chosen.

THE ROYAL AGRICULTURAL SOCIETY.

THE MEETING AT WORCESTER.

(*From our Special Correspondent.*)

CONSPICUOUS in the midst of the agricultural implements, a great variety of hydraulic apparatus was also exhibited; amongst which we noticed the peculiar pump exhibited by Mes Norton. Its construction is well explained the name by which it is known. The "V shaped pump, then, instead of having a cylinder, and plunger or piston, which is const wearing loose and becoming leaky, has a bed, with a sliding V piece working there without packing. We have already fully described this admirable pump in the MECHANIC MAGAZINE for April 24, 1863; the inven really deserves the high character it has received from those who have tested its meri

Messrs. Merryweather exhibited their well known steam fire-engine "Torrent." Although there were no facilities for a full display of its capabilities, its steam was got up and it was kept at work pumping water from one tank to another. After the close of the show, the engine was tried in the city be several of the authorities, who expressed themselves much pleased with its performances.

Messrs. Warner exhibited a great variety hydraulic machines. Amongst other arti we noticed a large double-action pump moun on wheels (this pump has been purcha for India); also a double 6 in. pump work by steam, throwing about 120 gallons a min and a great number of other articles, all displaying that excellence of design and workmanship for which the firm is so justly celebrated.

THE TRIALS.

The following is the continuation of the report on the trials; which we were oblig omit last week from want of space*:—

The Steam Cultivators.—The prizes offe for this class of implements consisted of and a gold medal for the best applicatio steam power for the cultivation of the soil, of £50 for the best application of steam po which may be effectually and safely adapted small occupations. The judges were th agricultural gentlemen—Mr. Jacob Wi (Northumberland); Mr. C. Sewell R (Norwich); Mr. H. B. Caldwell (Wilt assisted by Mr. William Owen, a Rotherha engineer. As usual, Mr. Fowler got the li share of the prizes. For his large steam tac he received the gold medal and £30; the remainder (£20) going to Mr. Savory. Of th prizes for small steam tackles, Mr. Fowler received £25; Mr. W. Smith (Woolston), £1 Mr. Howard, £10; Mr. Stevens, one of ten silver medals devoted to miscellane awards; while Mr. Coleman was "commende The decision regarding the Bedford firm caus some surprise, as their system embodies considerable mechanical improvements over th of Mr. Smith of Woolston. Collinson Hall a Hayes, of Stoney Stratford, were also com petitors in this line. In the show yard Be of Stow, exhibited a combined steam plo consisting of an iron frame on wheels, at e end of which were attached ploughs hung joints, and to be lifted from the ground by wheel and pinion. Fisken, one of the origi inventors of the balance-plough and self-act anchor, showed both these articles at Sta No. 165. Mr. Williams (Wilts) made appearance with a steam plough forme three wrought-iron frames, holding coulters on separate centres, independen the outside frame.

Mr. Fowler, in the course of the trials, employed his three different systems—the si traction engine, with its clip-drum and s acting anchor; then two engines on the oppo site headlands; and lastly, the plan he brou out last year for working small occupat by means of a portable engine. He us

* At page 522 of our last number, and at the 13th from the bottom of the first column, there is a self-e misprint of "*engine*" for "BRAKE."

one of Clissold's bevel-edged belts (described in our number for March 20, p. 214), for communicating the motion from an ordinary portable engine to a carriage in front, supporting a clip-drum, and working a self-acting anchor at the opposite headland. Fowler's usual balanced tool was used by himself, and by Savory, Collinson Hall, and Hayes.

Hayes, of Stony Stratford, used a similar implement to the one he exhibited in the Eastern Annexe of the International Exhibition. It consists of a 10-horse stationary engine and a windlass, the winding-drums of which are driven by a strap, which can be shifted at pleasure, thus doing away with objectionable gearing. He uses cords laid along the fields, for altering his windlass by the man at the anchor. There is no doubt that Mr. Hayes' system has great merit, and it is certainly very ingenious. Unfortunately, this tackle came to grief on the very first day of trial (Wednesday, 15th), through a coil of rope getting accidently caught in the gearing of the windlass, and thereby smashing nearly one-half of the drum.

Mr. Collinson Hall appeared with one of Turner's 10-horse traction engines, working his steel chain upon a polygonal drum. The chain is formed of circular steel rods and short flat plates riveted at the joints. There is a difficulty in keeping it off the ground, that must add to the consumption of power of the engine, and the wear and tear of the chain; and the whole apparatus did its work rather slowly, from the machinery for setting the rope to the variations in length of the furrow being as yet incomplete. He used Fowler's plough and anchorage. The steel rods of Hall's peculiar chain were about 18 in. long, and ¾ in. in diameter, being riveted to 4-inch plates. They are stated to cost nearly £7 10s. per 100 yds., and to weigh about 1 lb. per lineal foot.

Mr. W. Smith, of Woolston, worked his 3-tined cultivator and windlass with a double cylinder 10-horse engine of Butlin, of Northampton. It at present combines a cultivator and drill, weighing nearly half-a-ton less than the one exhibited at Battersea last year. The framing is balanced on a pair of wheels, and the whole implement is very manageable. The windlass and grubber were worked by Mr. Smith's usual well-known tackle.

Mr. Steevens, of Hammersmith, competed with a Howard's tackle, driven by a traction engine of Garrett of Leiston. His plough may be shortly described as being a great improvement upon the Fisken plough, described in the famous patent, No. 1629, year 1855. The two sets of ploughs balance each other, and they are raised and lowered by a screw and toothed segment. It is a very neat and well-arranged implement, and it does credit to its manufacturer, Mr. Woodbourne, of Kingsley.

Messrs. Howard, of Bedford, worked their double-framed cultivators with one of Clayton and Shuttleworth's 10-horse double-cylinder engines and the usual stationary windlass with coiling chains; the rope laid all round the field, and the slack rope being kept off the ground by means of their ingenious double compensating snatch block.

Coleman and Sons brought their two cultivators, worked by their 10-horse double-cylinder engine. In this system, two implements are alternately pulled between the engine at one headland, and a light anchored pulley on the opposite headland.

The steam cultivation system that attracted the most attention, from its novelty and originality, was that of Messrs. Savory and Son, of Gloucester. They employ two 10-horse power double cylinder traction engines at the opposite headlands. A 6 ft. drum—capable of taking in at one lap 570 yards of rope—is hung upon friction rollers on the boiler barrel of the engine. The rope is fed on to the drum by a pair of small rollers, worked to and fro on a screw shaft. Each engine alternately draws the implement towards it, while the other is running free and advancing along the headland in position for the next furrow. This system is very ingenious, and well deserves the prize it has received from the Royal Agricultural Society. Whether it will keep its ground is a different question. We did not see any arrangement for taking up the wear between the friction rollers and the inside of the drum, nor would any appliance with this intention be very feasible. There must also be a considerable strain upon the boiler seams, and we should say that there must be occasionally some waste of power when the screw passing the rope on to the drum gets slightly ahead of its work.

Mr. Fowler's double engine seemed to us to be equally efficient with Savory's plan, without its drawbacks. Each of the 10-horse power traction engines was furnished with a common vertical winding-drum underneath, with a very simple contrivance for coiling the rope. The double cylinder arrangement is evidently the best for large occupations, and for doing work by contract. Fowler's apparatus of that class adapts itself remarkably well to fields of irregular shape—the rope coiling easily on the drums at any angle.

In a full account of the trials of the steam cultivators, the usual chapter of accidents would take up a large share. On the first day (Wednesday) Fowler burnt out his fire-box plug, from the water getting too low, before he had completed his 1½ acres of ploughing. Collinson Hall was disabled before reaching the ground. Steevens could not work, through several mishaps. Messrs. Coleman's cultivator also met with an accident; and Hayes completely disabled his apparatus for the remainder of the trials. Smith did his work slowly, but well, and Howard made excellent work with his cultivator. Savory very rapidly completed his 1½ acres with one of Fowler's ploughs, manufactured by the Messrs. Ransome. On Thursday, Coleman again broke his cultivator. Fowler, employing three men and three boys, and using 3 cwt. 3 lb. of coal, did 2 acres in 1 hour 57 minutes. Howard, with four men and two boys, grubbed up the same extent of land in the same time; while Savory, employing three men and one boy, and also using Howard's 3-tined grubber, accomplished a similar performance in 1 hour 41 minutes. The latter lost about ten minutes through accidentally breaking an eye off his rope. On Friday, we saw Mr. Fowler doing some extraordinary work, breaking up with his 12-horse engines and digger a soil that looked like a surface of cast-iron; and his plough worked through, turning up solid 12 inch cubes of earth. He did 1 acre 3 roods and 28 perches in 2 hours 33 min., consuming 5 cwt. of coal. Coleman again broke his cultivator, but afterwards did some excellent work. Steevens' plough, worked by Savory's engines, also did some very good work. The general results of the trials seem to be a triumph for the direct-acting system, exemplified in Fowler's and Savory's double-engine plan. The saving of rope, the economy of time in adjusting the tackle, and the general simplicity of the mechanism seem to point to this plan as the steam tackle of the future. If an arrangement could be successfully carried out, for employing the portable engines in this manner, by making them self-propelling, it would no doubt meet with great success in all steam-ploughing operations.

Mr. Amos employed a novel and simple dynamometer, of his invention, for testing the draught of the steam ploughs. It consists of a piston, in a cylinder partly filled with water contained in an india-rubber bag, the bottom of which is between the two discs forming the piston. The edges of the bag are also tightly bolted between the cover and the cylinder, thus forming both the piston and cover joints. One of Bourdon's gauges is screwed on the cover. A hook being fixed to the bottom of the cylinder, and a second hook to the piston, the strain at both ends causes the pressure given out by the piston on the water to be communicated to the Bourdon gauge. This instrument only requires a registering apparatus, to render it complete. The ground, however, where these trials were conducted, was so clayey and indurated, that accurate dynamometric experiments were scarcely practicable; partly from the jerking action; and, on the other hand, from the difficulty of ascertaining the real depth of the work.

The Thrashing Machines.—These barn implements are not much altered in construction from those exhibited at Battersea last year. As we observed in our last, Bruckshaw and Underhill's elevator seems to be getting into more general adoption, but the machines provided with this apparatus gave rather unsatisfactory results at the trials. In fact, the machine of the latter exhibitor was unsuccessful through the choking of the patent elevator. The blast, however, in its various forms, is sure to spread in its applications; and there is no better means of simplifying combined thrashers, or one that offers a better prospect to those determined to simplify the thrashing machine—*coute qui coute*.

Those useful appendages, Coulson's patent wood spring hangers are also getting largely employed, and their use evidently diminished the number of working parts and the strain on the framing of the machines. The machines were driven by one of Clayton and Shuttleworth's 8-horse engines. The thrashing machine judges were:—Mr. Gibson Martin, Thorney, near Peterborough; Mr. Wm. Chalcraft, Brimsholt House, Lephock, Hants; and Mr. John Hicken, Bourton, near Rugby. One hundred sheaves were allotted to each machine, 15 being allowed for bringing it into working order. The points for the consideration of the judges were:—the time taken by each machine for thrashing the hundred sheaves, the cleanness of the sample, and the engine power consumed. The samples were not tested by the judges by screening and weighing, as at Chester—a rather rule of thumb mode of procedure. As will be seen, the machines were very numerous, and in some cases the judges allowed a second or third run when any misfortune occurred. This caused some dissatisfaction in the competitors of the machines so favoured. The prizes offered consisted in £50 for the class of portable combined steam thrashing and finishing machines, and £20 for similar fixed machines.

An exhibitor showing two machines differing essentially in principle, was allowed to try both. The general results are given in the following table:—

TABLE No. 1.

Combined Finishing Thrashing Machines.

Name of Exhibitor.	No. in Catalogue.	Time in which each Machine thrashed 100 sheaves of wheat.		Average Horse-power required by each Machine.	Horse-power that would be required to thrash 100 sheaves in one minute.

Seven of the machines in the above table were weeded out; and each machine received 500 sheaves for the experiment, and 20 for getting the machine into running order. The results are given in the following table. The division of the £50 marks the relative order in merit of each machine in the opinions of the judges:—

TABLE No. 2.

Combined Finishing and Thrashing Machines. Selected and Frictional Trials.

Name of Exhibitor.	No. of Article in Catalogue.	Time in which each Machine thrashed 500 sheaves of wheat.	Average horse-power required by each Machine.	Horse-power that would be required to thrash 500 sheaves in one minute.	Horse-power required to drive each Machine empty.
		m. s.

Barrett & Co.......	2,540	20 55	8·49	177·44	4·089

N.B.—Each machine was run empty for 5 minutes, and the result recorded as per last column.

In the class of fixed barn-works, four machines were exhibited, two of which were weeded out—one of them relinquishing the trial from some derangement in the dressing apparatus. According to the expressed opinions of the judges, the winning machine left nothing to be desired in the work it accomplished.

TABLE No. 3.

Fixed Barn Works.

N.B. The Machines were run empty during a period of 5 minutes. In all these tables 1 horse-power is taken as being equal to 33,000 lb. lifted 1 foot high per minute.

The power consumed in driving the thrashing machines was ascertained by means of an ingenious dynamometer, constructed at the works of Messrs. Easton and Amos. We hope to be enabled to give an illustrated description of this interesting apparatus, and, in the meantime, we will shortly describe its general arrangement:—The pulley driven by the strap from the engine was attached by means of four curved springs to the pulley driving the thrasher. The springs are graduated to 153 lb. at the circumference of the pulley. When—through any extra strain on the thrasher—this pressure is exceeded, the pulley driving the machine gives way, and, being loose, it turns round on the shaft. A double circular inclined plane, fixed to the loose pulley, revolves with it, and, pressing on a spring, it thrusts forward a small spindle fitted inside the shaft. To this spindle a small smooth disc is fixed at right angles, and it presses against another larger disc. This latter is caused to revolve by a train of wheels; a continuation of the same train forming a counter for the registration of the number of revolutions of the engine. When the small disc is at the centre of the larger one, no motion is produced, and of course no registration is then required. On its being in the least thrust out of the centre, however, it is caused to revolve by its friction against the larger discs, and it then transmits its motion to a square spindle upon which it slides. This spindle again communicates its movement to another train of wheels, forming a second counter, upon which, at the end of the operation, the total amount of the power consumed can be read off. The small disc is thus, in its normal position, at ⅛ of an inch from the centre of the larger one; and in that position it represents a pressure of 153 lb. So delicate is this apparatus, that the different stages in the feeding in of the sheaves were very plainly indicated.

According to Mr. Amos, the thrashing machines generally were of a higher order of construction and workmanship than any exhibited at previous shows. The corn-dressing machines were not tested with regard to the power consumed—by means of the dynamometer; as, through an unfortunate omission, the exhibitors were not previously requested to have these machines provided with the exact diameter of pulley required by the instrument.

We must now conclude our notice of the Worcester Show; at the same time regretting that we have not more space at present to devote to the subject.

TRIAL OF THE "MANHATTAN."

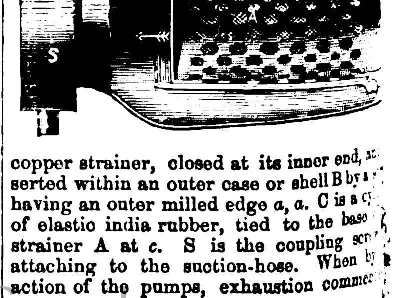
THIS engine, which has received a partial repair at the hands of Messrs. Shand and Mason, underwent some experiments on Saturday, in the presence of a numerous body of engineers and others concerned in such matters. The trials were conducted at the Shadwell entrance to the East London Docks; the site was extremely convenient for testing alike the drawing and forcing powers of the machine, the vertical distance from the rotary pump to the surface of the water in the basin being nearly 15 ft. Steam was got up a little after 1 o'clock; the times and pressures were nearly as follows:—In 1[...] from the application of the match, the [...] got to work with steam at 20 lb., drawing [...] immediately, without priming the pump; in [...] the pressure was 40 lb.; in 15 m. 45 lb., [...] the engine was stopped for a short tim[e] [...] 15½ m. the pressure was 55 lb.; in 16 m. [...] at 62 lb. the engine started, throwing [...] steady jet through a 1¼ in. nozzle to a di[stance] of about 150 ft., with a pressure in the air-[vessel] of about 80 lb; in 18 m. 40 s. a pressu[re of] 100 lb. was reached, with 140 lb. in the air-[vessel]. The engine making about 280 revolutio[ns per] minute, some very fair work was done; [at] this juncture a leak was sprung in the b[oiler], which, though very trifling, so far damp[ed the] fire as to render it impossible to keep [...] After a little time the leak stopped itself, the fire was re-lit, but without producing very good results. Whether from a defect [in the] quality of the coal, or that the boiler has [been] more injured than appears at first sight, [it was] found impossible to keep up the water [...] and the pressure in the boiler at the same t[ime], the introduction of the feed pulling dow[n the] pressure with a rapidity which was very re-markable. The engine and pump of the ma[chine] leave little to be desired; but the boiler [...] cannot accomplish better results than [...] have seen, must, we fear, be pronou[nced a] failure. After a couple of hours, the coal [pro]vided having been consumed, all further [...] ceased, the engine returning to London.

Captain Shaw, of the London Fire Br[igade], gave a very handsome entertainment th[e] evening, at Watling-street, to Mr. Van T[...] the other American gentlemen who accom[panied] the engine from New York. About twe[nty] of his own men were present, in compa[ny with] many gentlemen well-known for the in[terest] they take in all that appertaineth to fire [and] their suppression. The Duke of Suth[erland] honoured the board with his presence [...] evening. The large hall, usually devoted [to the] reception of the engines, was converted [into a] handsome tent by a skilful arrangement of [...]ing. With such a host as Captain Shaw, w[e need] not dwell further on an act of hospitality [...] was a courtesy, in the fullest sense, gra[...] paid to foreigners who well deserved it.

BADDELEY'S VALVED SUCTION STRAINER.

IT is well known, that when pumps or fire-en[gines] are lifting water from great depths, a [...] slight defect in any part of the suction-pi[pe or] its joints occasions much trouble and [annoy]ance, especially if the engine discontinues [work]ing for a short time, as the whole of the [water] immediately runs out of the pipe, and wh[en the] engine resumes working, has again to be [drawn] from its original low level. To obviate [this a] foot valve has sometimes been placed at th[e bot]tom of the feed-pipe. Mr. Baddeley, C.E. [has] recently designed and registered a valved s[trainer] for fire-engines, &c., which was successfu[lly em]ployed in the late trial of steam fire-eng[ines at] the Crystal Palace.

The accompanying drawing is a section[...] of this strainer. A is a cylindrical per[forated]



copper strainer, closed at its inner end, an[d in]serted within an outer case or shell B by a [...] having an outer milled edge *a, a*. C is a cy[linder] of elastic india rubber, tied to the base [of the] strainer A at *c*. S is the coupling scr[ew for] attaching to the suction-hose. When b[y the] action of the pumps, exhaustion comme[nces]

ıotion-pipe, the water rushes through the rations of the strainer, distends the india ır, and passes up the suction-pipe to the ıs. If the working of the engine is stopped, ıdia rubber closes round the perforations prevents the return of any water through ; by this means the column of water is tained, for any length of time, close up to uction valves of the engine, and no loss of ensues when the engine resumes working.

ɜITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

thirty-third meeting of the British Associa- for the Advancement of Science will com- ce in Newcastle-upon-Tyne, on Wednesday, 26th of August, 1863, under the direction of following officers:—President:—Sir William Armstrong, F.R.S. Vice-Presidents:—Sir ter Trevelyan, Bart.; Sir Charles Lyell, D., D.C.L., F.R.S., F.G.S.; Hugh Taylor, .; Isaac Lowthian Bell, Esq.; Nicholas od, Esq.; the Rev. Temple Chevallier, B.D., .A.S.; William Fairbairn, Esq., LL.D., .S. General Secretaries:—William Hopkins, ., M.A., F.R.S., St. Peter's College, Cam- dge; John Phillips, Esq., M.A., LL.D., F.R.S., ofessor of Geology in the University of Oxford, iseum House, Oxford. Assistant-General Se- ıtary:—George Griffith, Esq., M.A., Deputy ofessor of Experimental Philosophy in the Uni- rsity of Oxford, Jesus College, Oxford. General easurer:—William Spottiswoode, Esq., M.A., R.S., F.G.S., F.R.A.S., &c., 19, Chester-street, ılgrave-square, London, S.W. Local Secre- ries for the Meeting at Newcastle-upon-Tyne: Captain Noble, Augustus H. Hunt, Esq., and . C. Clapham, Esq., 5, Grey-street. Local reasurer for the Meeting at Newcastle-upon- yne:—Thomas Hodgkin, Esq.

The General Committee will meet on Wednes- ay, the 26th of August, at one p.m., for the elec- on of sectional officers, and the despatch of usiness usually brought before that body. On ıis occasion there will be presented the report f the Council, embodying their proceedings uring the past year. The general committee vill meet afterwards by adjournment.

The first general meeting will be held on Wed- ıesday, the 26th of August, at 8 p.m., when the President will deliver an address; the concluding meeting on Wednesday, the 2nd of September, at 3 p.m., when the Association will be adjourned to its next place of meeting.

At two evening meetings, which will take place at 8 p.m., discourses on certain branches of science will be delivered.

There will also be other evening meetings, at which opportunity will be afforded for general conversation among the members.

The Committees of Sections will meet daily, from Thursday, the 27th of August, to Wednes- day, the 2nd of September inclusive, at 10 a.m. precisely.

The Sections will meet daily, from Thursday, the 27th of August, to Tuesday, the 1st of Sep- tember inclusive, at 11 a.m. precisely.

The following are the titles of the sections to which communications may be presented:— Section A. Mathematics and Physics. B. Chemistry and Mineralogy, including their applications to Agriculture and the Arts. C. Geology. D. Zoology and Botany, including Physiology, Sub-Section D. E. Geography and Ethnology. F. Economic Science and Statistics. G. Mechanical Science.

Notices of communications intended to be read to the Association, accompanied by a statement whether the author will be present or not at the meeting, may be addressed to George Griffith, Esq., M.A., Assistant-General Secretary, Jesus College, Oxford; or to Captain Noble, Augustus H. Hunt, Esq., and R. C. Clapham, Esq., Newcastle-upon-Tyne.

The iron-clad "Roanoke," supposed to be the most formidable vessel in the Federal service, has proved a failure for sea-going purposes, and has been retained for the defence of New York Harbour.

HOLDEN'S APPARATUS FOR WASHING WOOL.

FIG. 1.

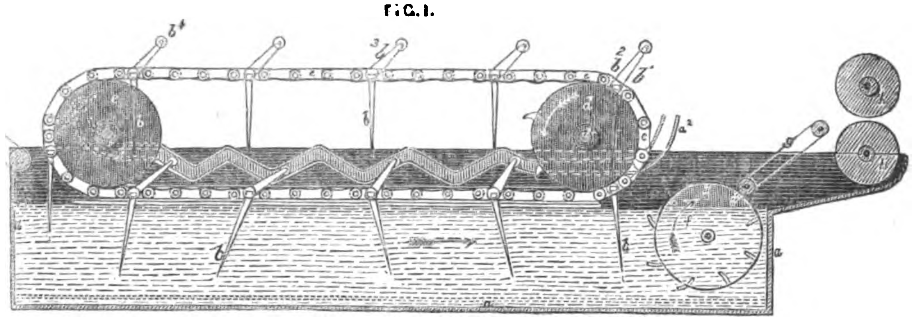


FIG. 2.

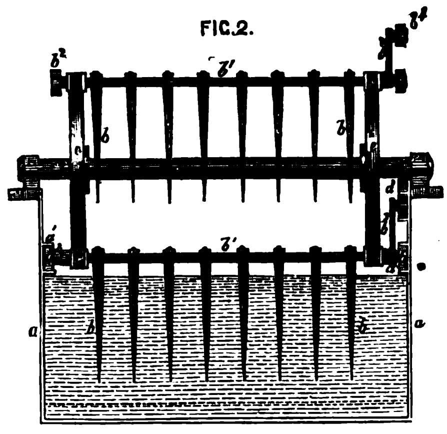


HOLDEN'S APPARATUS FOR WASHING WOOL.

The following improvements in machinery for washing wool have been recently patented by Mr. Isaac Holden, of Bradford. The invention relates to means by which the fibres are operated upon whilst being conducted through the trough of wash liquid by prongs, grates, or other surfaces adapted to conduct the fibres in effecting the washing thereof, and have for their object to effect an intermittent forward and partial retrograde action to such means. For this purpose the prongs, grates, or other instruments may be applied to plates or bars, or carriers, which are controlled to move in irregular courses, or in courses with alternate progressive and retrograde action, by which such instruments, during their progressive motion, will effect a forward and partial backward action to their points or operating ends upon the fibre.

Fig. 1 shows a longitudinal section, and fig. 2 a transverse section, of apparatus for washing wool and other fibres with parts arranged according to this invention.

a, a is the bowl or trough of wash liquid in which is placed the fibre to be cleansed. The wash liquid is supplied to this bowl or trough by any suitable means, and the fibre to be washed is fed thereto at the point A by a feed-cloth, or by other suitable means; *b, b* are prongs, or they may be grates or other surfaces adapted to conduct the fibres through the bowl or trough *a* in effecting the washing thereof. These prongs *b* are affixed to bars, which are at their ends formed into necks, which pass into links of the chains *c, c*, by which those prongs may have progressive motion given to them with progressive motion given to the chains. Each end of each of the bars is also provided with a truck or bowl b^2, which passes between fixed guides, and are thereby correctly supported whilst traversing through the trough *a*. These bars are also provided with arms, with trucks or bowls, which pass into grooves formed between the fixed but curved bars a^2, a^2, by which the points of the prongs, in addition to their progressive motion imparted by the chains *c*, will have given to them, according to these improvements, an intermittent or forward and partial retrograde action. The chains *c, c* pass over drums or pulleys *d* and *e*, and are fixed respectively to shafts supported so as to be capable of revolving freely in suitable bearings. The axis of the drum *d* has motion given to it by a steam engine or other suitable power to give motion to the chains in the direction of the arrow. The fibre having been carried through the trough *a* from the point A to the point B by means of the prongs *b*, or by grates or other suitable surfaces operated, as described, it is thence raised out of the trough by means of a lifting drum *f* with arms capable of protruding for a time, and then of receding within the periphery of such drum during its revolution, such as is now well understood, or by other suitable means, and thence by the endless apron *g* to between the squeezing and expressing rollers *h, h*. The action of the instruments *b* causes the fibre under operation to be alternately drawn upon or pushed forward, and then relieved from such pressure in its passage through the wash liquid whilst a slight agitation will also be obtained, by which the wash liquid employed will be capable of acting more freely on all parts of the fibre, thereby facilitating cleansing without stringing or felting it.

SAFETY-LAMPS.

At the May meeting of the Manchester Geological Society, a discussion took place on the safety of the safety-lamp—a subject which has of late excited considerable attention amongst mining engineers. The subject was introduced by Mr. Binney, who said:—At a meeting held here on the 26th of February, 1861, a gentleman from London (Mr. Philip Holland) sent some seals for looking Davy-lamps. Mr. Holland was at that time not content with stating that his seal was a very capital plan for preventing the opening of lamps, but he also made a very strange assertion. He said, "There is no well-authenticated instance of explosion in a proper safety-lamp." That was the expression made use of. I then stated that this was a very serious matter, and the words I used were—"Now, I say there are many instances. The inventor of the Davy-lamp never said it was impossible to explode fire-damp by one of his lamps, because he knew it could be exploded, and he always cautioned people not to move the lamp against a current of air. We know that lamps are commonly moved against currents of air. He never expected there would be coal dust accumulated on the wire gauze, and then oil spilled upon such coal dust, and the lamp, without being cleaned, allowed to become full of flame. I have myself passed flame through standard gauze which has been covered with coal dust and oil. It is well known that lamps are frequently covered with coal dust, and nothing is more common than oil to be spilled on them. Yet here is a gentleman who sends forth to the world a lock with this dangerous advice—that a 'proper safety-lamp cannot be exploded.' I should like to ask the gentlemen present whether it is not possible to explode a safety-lamp?" Then there followed a long conversation, and many of the gentlemen present wanted to make it out that they did not know of any explosion when the lamp had been properly used. Mr. Livesey, for instance, said—"I know one case where a safety-lamp did fire, and several men were killed. The men finding the lamp get hot, laid it down; the others thinking that if left it might be burnt through, one man

went to fetch it, but it was so hot he let it fall, and the oil running out, it exploded." This was clearly a case of working with a hot lamp and an explosion. In some mines in former times, it certainly was frequently the custom to work with hot lamps. I have been in many mines where most of the lamps appeared to be getting hot, and the men did not take the slightest notice of them. This subject was discussed at a second meeting, and many gentlemen would not admit that such lamps could be exploded. I will, however, now repeat my opinion that the Davy-lamp can be exploded. The chairman did not commit himself so far as the rest, but it was the general opinion that the lamp could not be exploded; that lamps having coal dust and oil about them were not fit to be used; and that the lamps were not cared for as they should be. But in the North of England more decided opinions are now held. In the MECHANICS' MAGAZINE of April 17, there is a report of the North of England Institute of Mining Engineers upon the subject. One of the greatest authorities of the day in the coal trade (Mr. Nicholas Wood) gives an opinion which is entitled to much respect. The general impression in the North, I know, has been held for a long time that the flame would not pass through proper gauze, although the South Shields committee, in their most admirable report, published many years since, declared and proved the contrary to be the fact. What Mr. Wood here says is entitled to the greatest consideration, because it is contrary to what has been advanced before, and contrary to the ideas entertained by the audience whom he was addressing. He says—"His attention had been drawn to the subject by Mr. Greenwell, who had visited a colliery where they were in the habit of heating all their lamp gauzes red-hot previously to using them, to prevent their exploding the gas should they become red-hot in an inflammable mixture. The subject was one of very deep importance, and he (the President) had since made one or two experiments, by inserting new lamp gauzes into the interior of a short red-hot pipe, when explosions occurred from volatilization and subsequent inflammation of the oil attached to the gauze. He had tried, in a similar way, gauzes which had been thoroughly cleaned and brushed, also others after having been steeped in and thoroughly washed with a strong solution of alkali, and the same results followed. It seemed to him, therefore, probable that the oil was contained in the pores of the iron itself, introduced probably in the process of wire-drawing. He thought that the subject should be thoroughly investigated. Several explosions had occurred where safety lamps were in use, and which had never been satisfactorily explained. Careful experiments should be made further to prove the liability of a red-hot gauze to explode an inflammable mixture, and the circumstances under which this could occur; and if it be found that this liability really does exist, then remedial measures should at once be sought for and adopted. Some years ago he (the President) made several experiments on the safety-lamp, the results of which had appeared in their Transactions. The gas was on several occasions exploded by putting the lamp rapidly through it, after the gauze had attained a high temperature; and it was quite possible that the explosion was caused by the co-operation and subsequent ignition of the oil attached to the gauze. It would be well if these experiments were repeated to determine this. He thought the matter might very properly be left in the hands of the experimental committee, to arrange and carry out the necessary experiments." Now I think that after so great an authority as he saying that the gauze will admit of the flame passing through it, we should consider the subject carefully. He seems to think that some portion of the oil left in the wire in drawing it may have done it; but for myself I think in practice we could never have safety-lamps with much cleaner gauze than when they are new. They are far more dangerous when the oil has been spilled upon them after they have been covered with coal dust, and they have been handled by greasy hands. It is, in my estimation, a thing of great importance that a man like Mr. Wood should have his doubts as to the power of gauze in arresting the passage of flame, especially when we remember that hundreds of human lives depend upon it. It seems very strange to me that after nearly all the leading colliery proprietors in the North and other parts of England have been preaching the infallibility of wire gauze for thirty years, the foremost man of all now says such lamps are not safe, owing to a small quantity of oil left in the wire. Surely no time ought to be lost by those who trust the lives of their men to such lamps, in determining the truth of this statement.

Mr. Atkinson said it would appear that at a high temperature the gauze is not safe, but that it then sets fire to the gas on the outside. It is generally explained that the gas is not fired through in consequence of the meshes cooling the ignited gas to some extent, so that it will not flame outside. But may it not be that the gauze can get heated to such an extent that it actually fires the gas outside? I think some careful experiments should be made to ascertain this.

The President (Mr. Joseph Dickenson): I have met with many people in the course of my practice who have been afraid to use a new lamp in fire-damp, and I presume it must have arisen from some known explosion with a new lamp having been handed down by tradition. In South Staffordshire I have met with such cases; and so much afraid have some people been of using even an old safety-lamp that they would not use it in testing for fire-damp unless it had a double gauze. The having a double gauze, however, is I think, going to too great a refinement, and gives scarcely any light. I believe if the lamp is in thorough order, and has had no oil spilled upon it, it is safe under any ordinary circumstances. But at the same time, in some of the collieries of this country, I think we have had too much reliance placed upon the safety-lamp, more so, in fact, than is allowed in other countries. In Belgium, for instance, they actually prohibit the use of the Davy, Clanny, and other lamps which do not become extinguished in an explosive mixture, but which are used so freely in this country. That is a point, however, that is too little recognized, and which deserves more attention from our mining engineers than it has hitherto received.

Mr. Atkinson: It appears probable that at certain high temperatures the heated wire will explode fire-damp the same as flame.

Mr. Binney: All admit now that a hot wire is dangerous. But I was once in Manchester at a lecture, when the late Dr. Murray said that a Davy-lamp red-hot was safer than a cold one.

The President: That is both rashness and ignorance.

Mr. Binney: Yes, and a very terrible thing to tell colliers. The fact is, an ordinary Davy-lamp is not the thing to trust a common miner with in an atmoshere of fire-damp. Many ignorant men, because this is called a safety-lamp, think it is a talismanic, and safe under all circumstances, and away they go and work without any fear. Safety-lamp is a bad name under such circumstances; although the lamp is safe under ordinary conditions, and good usuage, it ought on no account to be continually used in an atmosphere of fire-damp. If it does not go out when the gas is at an explosive point, it ought to be put out or removed.

The President: In my own knowledge, only a few years ago, the safety-lamps were too frequently kept in a bad state—the pricker holes were too large, and the meshes were not the standard measure, and the parts not securely fitted together.

HOROIZONTAL ENGINES.

THERE is an unaccountable prejudice on the part of cotton spinners, corn millers, and brewers against horizontal steam-engines. This prejudice is derived from no experience, for engines of the kind in question have not been put upon anything like a sufficient trial in cotton mills, corn mills, or breweries. Nor is the objection founded in reason, for the balance of fact and argument is decidedly against beam engines. They are heavy and costly, require costly foundations, and occupy a great deal of room, and for all this they present no compensating advantages. In respect of weight, which is a tolerable index of cost, we may compare the non-condensing beam engine exhibited last year in the International Exhibition, by Messrs. Mirlees and Tait, with a horizontal engine of the same power, by the same makers, and intended for the same purpose, viz., driving a large sugar mill. The beam engine had a 22 in. cylinder and a 4 ft. 6 in. stroke, while the horizontal engine has a cylinder of the same diameter, with a stroke of 4 ft., making a somewhat greater number of revolutions with the same speed of piston and same total power. In the case of the beam engine, the bed plate weighed 7 tons 14 cwt., the six columns 5 tons 2 cwt., and the entablature 3 tons 5 cwt., making 16 tons 1 cwt. of framing. The bed plate of the horizontal engine weighs 4 tons 13 cwt., or but little more than one-fourth as much, while its actual stability is even then greater than that of the other arrangement of framing. The working beam of the beam engine weighed 2 tons, 5 cwt., the whole of which is saved in the horizontal engine. The cylinder of the beam engine being supported upon its end, and being, also, 6 in. longer, weighed 17 cwt. more than that of the horizontal, which, with covers, weighs 1 ton 13 cwt. The 20ft. fly-wheel of the horizontal engine weighs 9 tons; that of the beam engine, working slower, weighing 13½ tons, although we cannot charge any difference in this respect to the mere arrangement. The whole weight of the beam engine was 44 tons 9 cwt., while that of the horizontal engine is less than 20 tons. The excess of weight fairly attributable to the beam arrangement may be set down as at least 15 tons, and the proportionate cost may be pretty correctly inferred from this difference alone. The difference in the space occupied would be chiefly one of height, which, in this case, would not, perhaps, be of great consequence. With a still larger single cylinder engine, the beam would occupy from 2,000 to 4,000 cubic feet more space than the horizontal. The difference in foundations is also against the beam. The supposed advantages of the beam engine are that the cylinder and piston wear better, and that the parallel motion may be more conveniently applied, and thus economise power supposed to be wasted in friction on the guides of a horizontal engine. If there are any other advantages we are unaware of them. Examining the points of objection against the horizontal engine, we will first consider the cylinder. in point of fact the wear is little, if any, greater than in the beam engine, and the seat of wear, Instead of being at the bottom of the cylinder, as most of those who object to the arrangement conclude, in view of the weight of the piston, that it must be, is confined almost entirely to the upper part of the cylinder. The side of a cylinder next to the ports is always somewhat softer than elsewhere, owing to the greater mass of metal there; the lubrication is not so abundant at the top as at the bottom, and if the piston chance to blow a little steam, the abrasion thereby caused in a horizontal cylinder will necessarily be on the upper side. A cylinder of good metal is a long time, however, in wearing, whatever may be its position, unless, of course, it is under the care of a careless engine-man. It is not, however, every kind of pig iron that will serve for a cylinder. Those of Messrs. Penn's engines are of Madeley-wood No. 3 iron, and several of the locomotive makers have found an advantage in mixing a moderate quanity of wrought iron turnings with their pig metal, the result being an iron of great hardness, while, except in very large cylinders, the mixture will run very uniformly. The great cylinders, from 70 in. to 112 in. in diameter, employed for screw engines, wear very slowly indeed. In the horizontal engine the piston is much more convenient of access, and the packing is likely, therefore, to be looked after with more care. When, too, the cylinder does become worn it may be easily and quickly bored anew withou moving it from its bed, the portable boring ap paratus now largely adopted in railway wo shops being employed for that purpose. As

the parallel motion, that might be applied to a horizontal as well as to a beam engine, and indeed a Wiltshire agricultural engineer has actually adopted radius rods for the horizontal piston rods of portable engines. We do not, however, approve of "parallel" motions. In the first place, the motion thus given to the piston rod is not mathematically rectilinear, and cannot possibly be made so. But, more than this, with the least inaccuracy in original adjustment, or what is more likely, that resulting from slight wear, the radius rods throw a heavy strain upon the piston rod. With a horizontal engine, if the crank is made to turn in the proper direction, the pressure of the cross-head is always upward upon the guides; and as the upward pressure due to the angularity of the connecting rod is not great, relatively, where the rod is long, its weight and that of the cross-head tend materially to diminish the friction upon the guides. The mean inclination of the connecting rod to the guides should not, and need not, exceed 1 in 10 throughout the stroke, and the friction due to this pressure should not exceed, and probably would not be as much as, one-tenth of this pressure, or the one-hundredth part of the actual steam pressure on the piston. This is without making allowance for the weight of the connecting rod and cross-head, which might diminish the upward pressure due to angularity to an amount which would not probably involve a loss in friction of the guides amounting to one-half of 1 per cent. of the whole power of the engine. The whole friction, however, upon the guides of a horizontal engine can hardly be as much as that brought upon the crank pin and main bearings of a beam engine, in consequence of the worse than useless strain exerted upon them, at every stroke, by the momentum of a heavy and rapidly vibrating beam. A moment's reflection must show the loss of power in changing the motion, sixty times a minute, of a beam many feet in length, and weighing several tons. Indeed, the presence of the beam prevents the adoption of that speed of piston at which, all things taken into account, steam-engines work most economically. This remark applies, of course, to both beams and side levers, the latter typifying the worst form of beam engine. It would be useless to consider the working of a beam engine with 22 in. cylinders and 40 ft. stroke, at 60 revolutions per minute. The strain caused by putting the beam into motion and bringing it abruptly to rest 120 times in a minute would be very great. It is this impracticability of rapidly vibrating a heavy beam that has retained the old standard of 220 ft. to 250 ft. of piston per minute so long in use. Remove the beam, and the other parts of the engine are perfectly adapted to work at twice that speed, the heaviest engine in the navy working regularly and constantly at nearly 500 ft. per minute, while there is really no difficulty in working at an even higher speed. It is because of the necessity for slow speeds imposed by the beam, that such absurdly heavy masses of machinery are to be found in our cotton mills, flour mills, and breweries, and sometimes, we regret to say, in the factories of engineers who should know better. Other things being equal, and provided only that the supply of steam is sufficient, the same engine may exert 100 or 400 actual horse-power, according as it may be driven at, we will say, 20 or 80 revolutions per minute, and conversely, a quick working engine may give off the same power as a slow moving engine, and with a saving of from one-half to two-thirds of its weight. Quick speeds require, at most, only a moderate extension of the bearing surfaces, the work in any case being supposed to be carefully done.

That the preference for a heavy rather than a light job, has had something to do with the recommendation of the beam engine by so many constructing engineers, we may reasonably suppose. There are other engineers, however, not less well informed, nor less successful in the character of their work, who prefer horizontal engines, and are able to assign good and sufficient reasons for their preference. As more generally constructed, there is no doubt that horizontal land engines have not had the advantage of the same workmanship which has been expended upon beam engines; and this circumstance is unfortunate, as tending to the prejudice of the most mechanical arrangement of the steam-engine, instead of being interpreted, as it should be, to the disgrace of the workman. Excellence of material, design, proportions, and workmanship should be accorded alike to beam and horizontal engines, and it will then soon appear that the latter are the most deserving of preference.

Some of the principal Scotch paper-makers have adopted, or are about to adopt, horizontal single-cylinder engines, and we find that, with either one or two cylinders, horizontal engines are slowly working their way into flour mills. Even setting aside their great advantage in point of first cost, we are convinced that, with first-class workmanship, they will ultimately prove themselves superior in every respect to beam engines.—*The Engineer.*

PARADOXES IN THE VENTILATION OF MINES.

AT a recent meeting of the Northern Institute of Mining Engineers, a Paper on the above subject, by Messrs. Atkinson and Daglish, was read, of which the following is an abstract:—

When alterations are to be made in the ventilating currents of mines, practical knowledge is generally relied on to effect these; but it sometimes happens that the anticipated results are not realized, some of the currents proving stronger and others weaker than was expected, and others even failing entirely to establish themselves. In other instances, after accidents have occurred, or when extensive alterations are in progress in the workings or ventilating shafts, whereby some of the ordinary arrangements for ventilation have been materially affected, particular parts of mines have had their ventilation deranged in a manner and to an extent entirely unanticipated. All these cases may, with some degree of propriety, be termed "paradoxes." The Paper then proceeds to describe and explain a number of very remarkable instances where this action has been observable; these all requiring diagrams to be illustrated. The following practical deductions from the cases instanced are thus made at considerable length:—

1. The danger that may attend the use of two open routes from a return air-way, to any part of an up-cast shaft, at a considerable height above the level of the furnace, when the air in one of the routes, in ascending portions, is raised to a much higher temperature than that in the other.

2. The danger that may arise from the injudicious use and application of dumb drifts.

3. The probability of a reversal of the current in the upper seams of any colliery, when the up-cast shaft is contracted above by a cradle or scaffolding during the progress of repairs.

4. The danger attending intercommon ventilation between two adjoining collieries, having separate down-cast and up-cast shafts, arising from the extreme probability of variation, not only in quantity, but even in direction, of some of the splits of air—in cases of the ventilating powers of either of the collieries being considerably increased or diminished.

5. The necessity of insuring that a distinct pressure exists on all stoppings in a direction from where naked lights are used; and that in all cases a return from an in-take split should intervene between it and any separation stoppings of another split.

6. The danger attending the use of regulating doors instead of permanent regulators, placed so as to have as little passage as possible through them.

The necessity of using safety-lamps only in cases of falls in the air-ways, or other causes tending greatly to diminish the gross quantity of air circulating, especially in mines having extensive workings, either to the rise or dip of the shaft; as, in either case, reverse currents from the directions of the goaves would probably be established.

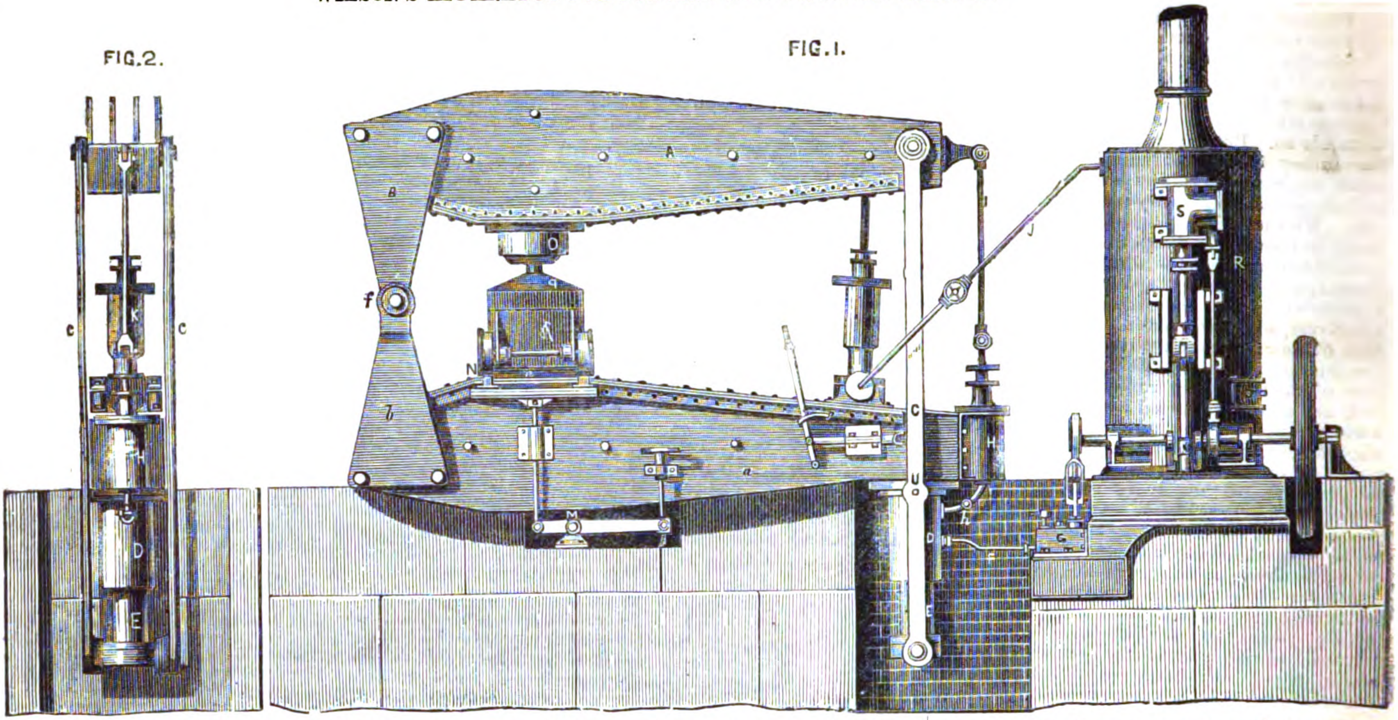
In conclusion, the title of "paradoxes" has not been employed to convey the idea that the ordinary laws of nature were either suspended, or in any way departed from, in producing the results given in these cases; but simply to imply that they were such as were not likely to be anticipated before they were observed, even by those experienced in the ventilation of mines. Cases like those described clearly demonstrate that the thorough and safe ventilation of a mine yielding fire-damp, requires for its accomplishment a great deal more than the mere obtaining and circulation of a large gross quantity of air. Indeed, after providing the power and means necessary, that great judgment, skill, and care should be exercised by the underground manager in making the arrangements for its proper and safe distribution. And, in addition to this, there is further required great and constant vigilance on the part of the subordinate agents; together with implicit obedience to discipline, and prudence on the part of each one of the work-people in the mine, in order to ensure even a moderate degree of safety, and of immunity from explosions of fire-damp. And with all these combined, explosions cannot be entirely prevented, for human prescience and forethought have their limit equally with human knowledge and skill, and all that we can hope for is the diminution of their frequency or the mitigation of their severity.

UNINFLAMMABLE STUFFS.

ON this important subject the French Academy of Sciences have received a report from MM. Payen, Velpeau, and Rayer, in which M. H. Chevalier's Paper sent in to the Academy on the 25th of January last, is discussed. From this report it appears that only three salts have hitherto been found that may be successfully applied to the purpose in question, viz., that of preventing ladies' dresses from catching fire. There are many other salts that would do the same, but not without spoiling the dye, or the gloss, or the texture of the stuff, &c. Of the three in question, the sulphate and phosphate of ammonia have the inconvenience of being decomposed by the heat of a smoothing-iron; but they are applicable in those manufactures where stuffs are stiffened by the action of hot air or cylinders heated by steam. They exercise no action upon either the thread or the colour of the stuff. The phosphate of ammonia may be mixed with half its weight of hydro-chlorate of ammonia. To obtain an efficacious solution, 20 per cent. of this mixture must be dissolved in water. A solution of 7 per cent. of sulphate of ammonia produces the same effect, and is therefore the most economical salt that the trade can employ. But in those cases in which the smoothing-iron cannot be dispensed with, as in linen, for instance, a solution of 20 per cent. of tungstate of soda should be preferred. To obtain the desired effect, all these solutions must be applied to the stuffs after they have been stiffened and dried, because starch is always used in a weaker solution than that required for these salts. Acid tungstates destroy the thread of cotton stuffs, like borax, alum, and other substances previously recommended. The tungstate of soda is prepared in Cornwall, where the tin mines yield a large quantity of wolfram. It costs from £12 to £18 per ton. The sulphate of ammonia costs about £14 per ton, and has hitherto been used for manure.

M. Sauvageon, a French investigator, has discovered that cotton cloth which has been exposed for a certain time to the vapour of burning sulphur, assumes such an amount of incombustibility, that although it will char and become brittle when held over the flame of a spirit lamp, it cannot be made to take fire, while under like conditions similar cloth, but unprepared in this way, is flamed immediately. If the alleged facts be borne out in practice, the problem is solved, for the simplest domestic means may be devised for subjecting, after being washed, all white clothing to the vapour of sulphur, which will tend to make it still whiter. Moreover, it may not prove necessary to repeat the exposure so often.

WILSON'S APPARATUS FOR FORGING AND PRESSING METALS.



WILSON'S APPARATUS FOR FORGING AND PRESSING METALS.

THE following improvements in forging machines have been just patented by Mr. E. B. Wilson, of 5, Parliament-street, Westminster.

The invention consists of a peculiar construction and arrangement of machinery or apparatus for forging and pressing metals and other substances, by the use of a powerful lever actuated by a screw, cam, steam, or hydraulic pressure, so as to produce either a constant or intermittent pressure upon the metal or other substance to be operated upon, such substances being forged or pressed into any desired form by the aid of suitable dies situate under the lever. One end of the lever is connected by a powerful link or strap to the end of a fixed beam which supports the die or matrix. The lever and beam are constructed either of cast or wrought iron or steel, and trussed or otherwise as may be found requisite according to the strength required. The free end of the lever is acted upon either by a screw or a cam, or by direct steam or hydraulic pressure, so as to give either a constant or intermittent pressure.

Fig. 1 represents a complete side elevation, and fig. 2 a front-end elevation of the apparatus.

A is the top or compressing beam, and *a* the corresponding bottom beam for receiving the die and taking up the pressure. These two beams are connected together at one end by powerful links or metal plates B, *b*, and work on the fulcrum or centre *f*. C, C are radial rods connected at their upper extremities to the front end of the top beam and at their lower ends to the opposite sides of the hydraulic ram E, working in the cylinder D. This cylinder is connected by a pipe F direct to the cistern of a hydraulic pump at G, which is worked by a steam engine S attached to the boiler R. Any other convenient arrangement of apparatus may however be employed in actuating the pump G. A water cylinder H (the piston rod of which is connected by a rod I to the lever or beam A) communicates by a pipe *h* with the cylinder of the hydraulic press, and holds sufficient water to fill that cylinder when the ram E is pressed down by the descent of the top lever A. By the use of this water cylinder or chamber H, the same quantity of water may be employed repeatedly without running to waste, since when the lever and ram E are raised the water in the cylinder D of the press will flow back again into the water cylinder H. Another advantage is, that the main cylinder D being filled by the water which is forced into it from the cylinder H as fast as the ram E descends, a saving of time is effected, inasmuch as a small quantity of water only (sufficient to give the final nip or pressure) is required to be pumped into the press through the separate pipe F. The lever is elevated by means of a steam cylinder K, the piston rod L of which is connected to the lever or beam A. J is the steam pipe which supplies the steam from the boiler R to the steam cylinder K, which cylinder is securely connected by a swivel joint to the beam *a*. P, *p* are the top and bottom dies; the top die P is connected by a ball-and-socket joint O to the beam A, and the bottom die is provided with running wheels as shown, whereby it can be readily brought under the beam A along rails or trams for that purpose. So soon as the die *p* is brought into its proper position over the beam *a* and under the top die P, the rail ends, shown at N, N, are permitted to descend a few inches so as to bring the bottom of the die *p* down upon a supporting block *n* on the surface of the beam *a*, when it is ready to receive the pressure of the upper beam and die P. The raising and lowering of the rails N may be effected in various ways, as by a screw spindle acting upon a lever M, as shown in fig 1. In order to maintain the lever or beam A elevated, the patentee employs a lever Q connected to a rod T, which is forked at one end, and works to-and-fro horizontally when the lever Q is moved. The forked end of this rod takes into a stud U fast in one or both the links C, and thus holds the beam elevated until released by the withdrawal of the rod T.

JORNS TIMEPIECES.

LETTERS patent have been granted to Heinrich Jörns, of Tessin, Mecklenburg, for improvements in clocks or timepieces.

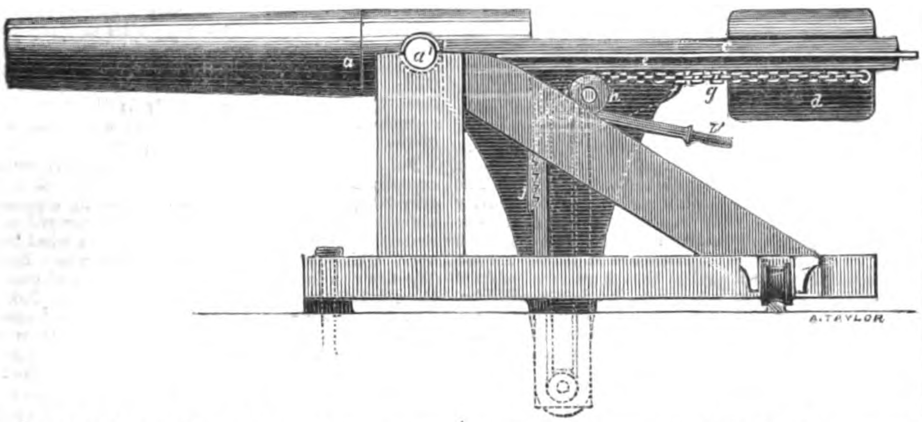
This invention is designed for obviating the necessity for winding up clocks or timepieces periodically, as at present practised. It is proposed to effect this through the agency of the variations in the temperature of the atmosphere, which is constantly taking place both inside and outside of dwelling-houses, and to employ the draught or current of air caused by such changes of temperature to set in motion certain mechanism to be connected to the ordinary mechanism of clocks, and by these means to produce a power sufficient to wind up a clock continuously, instead of having to wind it up by hand periodically, as at present practised. By this invention a great part of the weight at present necessary to keep the going parts of a clock in motion may be dispensed with; for example, a clock, which under ordinary circumstances would require four pounds to keep it going, may by this invention be kept going by the gravitating power of a weight of two ounces.

The following are examples of the means by which this invention may be carried into practical effect, that is to say:—The case containing the clock movements is formed with two vertical chambers, the foremost to contain the clock, and the back chamber for the passage of air by suitable inlet and outlet passages; the top or outlet passage aforesaid is provided with a flap valve, and the bottom or inlet passage is fitted with an ordinary revolving ventilator, upon the axis whereof a worm is formed, which gears into a worm-wheel for imparting rotary motion to wheel-work for winding up the going weight of the clock by means of an endless cord passing over a series of pulleys suitably placed. The action of the foregoing mechanism is as follows:—Suppose the clock to be only partly wound up, in this case the flap valve aforesaid will be open; suppose also that there is a hole made in that part of the wall against which the clock case is to be placed, the said hole will establish a communication by means of the aforesaid air chamber between the air both outside and inside of the room in which the clock is situated, and as the temperature of the air in the room varies from that outside of same, the effect will be to cause the air in the room to pass through the ventilator and outlet passage aforesaid, and thus impart motion to the winding mechanism connected therewith, and raise the going weight of the clock, and continue to do so until the weight is raised to its full extent, by which time a hook will have been brought into action and lifted a sliding piece of metal and weighted lever connected to the outlet air passage aforesaid, and by these means close the said air passage, by which the action of the ventilator will stop, and the winding up of the clock cease until the going weight aforesaid again descends by its gravity, by which the outlet passage will be again opened, when the winding mechanism will again come into action, and again raise the

BLAKELY'S IMPROVEMENTS IN BREECH-LOADING ORDNANCE.

FIG. 2.

FIG. 1.



going weight as before stated, and so on in succession, thus causing the said weight to be continually raised as it descends, the operation of winding being in effect self-acting, and constituting the feature of novelty in this invention.

BLAKELY'S IMPROVEMENTS IN BREECH-LOADING ORDNANCE.

THE following invention for improvements in cannon has been just patented by Captain Blakely.

The object of the first part of this invention is that the opening of the breech or separation of the breech-piece from the barrel may be effected by the act of firing, so that the firing of one charge will, in addition to throwing the projectile, open the parts and leave them in the position to receive a fresh charge. For this purpose the breech-piece projects into the barrel, and is retained in position by weight or elastic pressure proportionate to the power exerted by the pressure of the charge in firing. The firing causes the propulsion of the projectile, and at the same time the recoil of the breech-piece, thus opening the parts for the supply of a fresh charge. The breech-piece, enters the barrel to an extent sufficient to ensure its not leaving the breech end thereof until the shot or shell passes out of the muzzle. Holding means retain the parts when opened.

Fig. 1 shows a side view, and fig. 2 a plan, of a gun and parts connected with it according to this part of the invention; *a*, *a* being the body or barrel of the gun, supported by the trunnions a_1, a^1, in the carriage *b*. The dotted lines a^2, a^2, indicate the bore of the gun; *c* is the breech-piece, which is formed to enter the breech end of the gun, and, according to this part of the invention the breech-piece is affixed to or otherwise forms part of the block *d*, which has a groove formed in each side of it to receive the rails *e*, *e*, projecting from the end of the gun *a*, by which the block *d* with the breech-piece is supported, so as to be capable of sliding to and from the breech end of the gun, and in a line with the bore of it. The block *d* has a tendency to be drawn towards the barrel of the gun by means of a weight *f*, which, in combination with springs, are connected to the block *d* by chains *g*, *g* (or it may be by other suitable means); one end of each of these chains is connected to the weight *f*, and thence passing over a pulley *h* is connected at its other end to the block *d*, as shown. The weight *f* serves also as a platform or table for the support of the fresh charge and projectile previous to its being driven into the gun, and, by preference, a fresh charge is placed on this table, whilst the weight of that table is holding the breech-piece in the breech end of the gun. And when the parts are in the position indicated by the drawing, with the table raised, that table will hold the fresh charge correctly opposite the bore of the gun. The parts, as shown, are in the position they would assume after the firing of a charge, when the effect of the recoil has been to force out the breech-piece *c* with its block *d*, thereby overcoming the force exerted by the weight *f*. And in order that the block *d*, with its breech-piece *c*, may then remain in the position indicated until a fresh charge has been introduced, to the weight *f* a click or pawl *i*, and to the framing a rack *j*, are applied, by which when the weight *f* has been elevated it will be held up with the fresh charge thereon in position for loading. This charge must then be forced a short distance into the gun, and then by lifting the lever handle i^1 affixed to the click or pawl *i*, that click will be released ftom the rack *j*, when the weight *f* will descend again and draw the breech-piece to force the charge fully into the chamber of the gun; *k*, *k* are india-rubber or other elastic media adapted to act as buffers to resist shocks produced.

Secondly, the improvements relate to mounting ordnance to be fired through port-holes or embrasures, so that the axis of vertical motion is at or near the muzzle thereof, and at the portholes or embrasures. As in this case the weight of the gun and its carriage will not, as is ordinarily the case, be balanced near the axis of rotation, and consequently great power will be required to move them, it is preferred to apply the power required by means of hydrostatic pressure from a reservoir placed at a sufficient elevation, or by hydraulic apparatus.

ON THE WAVE OF HIGH WATER, WITH HINTS TOWARDS A NEW THEORY OF THE TIDES.

By THOMAS CARRICK, Esq.

THE author, starting from a new hypothesis on the relations of terrestrial matter to cosmical force, has arrived at the conclusion that the tidal motions of ocean surfaces are caused by a differential action of force centering on land areas. The nature of this hypothesis, and its relation to those motions, were briefly illustrated from the point of view of an assumed nebulous origin of the solar system. The author nevertheless declined to endorse the received "nebular hypothesis" as a genetic theory, and adopted its ideas and phraseology in his Paper solely from considerations of brevity in this incidental portion of his subject.

Assuming the existence of a diffused nebula, composed of ultimate atoms of matter each having a normal rotation on a fixed axis in a uniform direction, and with simple forces of attraction and repulsion arising thereout, then, from causes arising out of diverse molecular groupings of these atoms and their poles, the nebulous matter in condensing upon a centre might take up three successive states, constituting the normal types of the solid, liquid, and gaseous states of terrestrial science—the solid matter forming a spherical nucleus, everywhere covered with a concentric layer of fluid, and this overlaid with a gaseous envelope; these varying layers of matter being in stable equilibrium at the respective surfaces of contact. The force exerted upon such a sphere by another of like origin would therefore act by and through the intermediation of these three states—each successive stage of condensation, alike with a residual uncondensed nebulous matter of space, thus forming an essential link in the chain of gravitative action. But so soon as any portions of the solid nucleus emerge above the surface of fluid covering, into abnormal contact with the gaseous envelope, a differential action of enormous magnitude, centering upon these upheaved land areas would be at once originated, the first measure o which would be the cosmical value of the latent forces by which the fluid state of matter was constituted an essential intermediate link between the solid and gaseous states. In the view of the author, terrestrial matter in all its phases is now related to space, and to bodies in space, in a manner analagous to that which might have resulted from such a hypothetical origin. Not only does this matter exist in the three leading states of earth, water, and air, but each of the simpler forms of inorganic matter can, under given conditions, successively assume the solid, liquid, or gaseous state without undergoing any chemical change. This universal threefold relation of terrestrial matter points strongly towards the simple hypothesis, that the causal laws which now regulate these interchanges of state are the reflex of fundamental laws underlying the entire constitution of matter in the solar system.

Passing over the possible relation of the first land-upheaval to the early changes recorded by geology, and to the formation of heterogeneous solids, liquids, and gases, the differential force arising therefrom would be the initiating cause in the formation of the envelope of comminuted water or vapour which now encircles the whole globe. This vapour-ocean constitutes an intermediate state of matter in unstable equilibrium with other states at all surfaces of contact. By interactions arising thereout, the simple static conditions of force existing prior to land-upheaval are now, in the view of the author, partly replaced by more complex phases of force; and thus light, heat, electricity, and magnetism, which are expressions of these complex phases, which have their root in local reactions between unstable states of terrestrial matter at surfaces of abnormal contact when under the tension ot cosmical force—just as these "imponderable elements" are evoked in the voltaic battery by surface reactions of dissimilar solids and liquids in presence of atmospheric tension. In short, the ceaseless molecular changes and local motions of terrestrial matter would, on this hypothesis, be mainly referred to the differential action arising out of land-upheaval.

Recurring to the "wave of high water" which formed the special subject of the Paper, another phase of the present residual of that differential action would give rise to the tidal motions of ocean surfaces, the perturbative action centering on land areas, and attaining a maximum value on the shores of those areas. By discussing the hours of high water at full and change for the principal places of the globe, given in the Admiralty Tide Tables for 1863 (the data being r

reduced to Greenwich mean time), the author arrived at the following law of the progression of the wave of high water:—

In all areas in the northern hemisphere the wave of high water tends to revolve round the coast in the direction of the hands of a watch, and in like areas in the southern hemisphere against the hands of a watch.

Theoretically, this law should hold good in proportion as land areas approximate to the circular form, with wide uninterrupted ocean spaces all round. In a perfectly circular area of this kind, the differential action would have points of maximum and minimum effect on opposite shores at every instant, these together forming a nodal line, both ends of which would move simultaneously round the coast as the moon passed across the heavens, the wave of high water being everywhere the instantaneous expression of the differential force at its nodal point of maximum action.

By enclosing the continents and land areas which approach nearest to the prescribed conditions within one or more circles intersecting the salient parts of the coast, the author showed that whenever any systematic progression of the hour of high water could be distinctly traced, that progression is almost invariably in the required direction. Owing, however, to the irregular shape of all existing land areas, to the impossibility of including some of these in a single circle approximating to the coast line, and to the way in which some large areas are massed upon others with little or no intervening ocean spaces, many instances of anomalous results are found; and yet, when rightly considered in relation to disturbing causes, even these tend indirectly to confirm the method of grouping the data of tidal hours in relation to land areas as causal centres.—*Proceedings of the Manchester Literary and Philosophical Society, Physical and Mathematical Section*, April 30, 1863.

ON THE STATE OF CARBON IN CAST IRON.

The following Paper, by William Crossley, F.C.S., has appeared in the *Chemical News*:—

I have long been of opinion that anything throwing light upon the chemical constitution of cast or wrought iron and steel is of great importance, and I submit the following considerations, which are partially supported by experiment, as tending in this direction.

In analysis of cast iron the carbon is generally shown in two states—viz., combined and uncombined; combined as a fusible carbide, uncombined as graphite disseminated throughout the mass of the iron; and, according as the graphite or the carbide predominates, we have grey or white iron. The white is said to owe its peculiar properties to containing but little graphite and much carbide. The grey, on the contrary, contains but little carbide and much graphite, or free carbon.

I don't know why these views should be held, never having seen any reason given. They are the views, however, generally held, as may be easily shown.

In the *Chemical News* for Saturday, January 31, 1863, in a Paper on the Chemical Constitution of Iron, &c., by General Sobrero, of Turin, the following passage will be found:—

". . . The cast iron is agitated until the moment it solidifies; for this reason, carbon cannot crystallize separately, but remains in combination, hence white iron results."

F. A. Abel, Esq., in a lecture at the Royal Institution, April 27, 1860, says:—

"In looking at these specimens of cast iron, you will be at no loss to discover a very considerable difference in the appearance of most of them—a difference which is borne out by fully as great a variation in their physical properties and chemical composition. Here is a very dark specimen, with glistening fracture, containing a considerable portion of carbon in a peculiar condition—in the graphitic form, as it is called."

Miller, in his "Inorganic Chemistry," p. 879, says:—

"In many varieties of cast iron the carbon exists in two distinct forms—one portion being chemically combined with the metal, the other mechanically diffused through it as grrphite—the scales of which may be distinctly seen with a magnifying lens, when the surface of a newly-fractured bar is examined; these scales remain unacted upon when the metal is dissolved in dilute acid."

I have frequently had occasion to examine samples of grey iron with a lens, and never yet have I seen the scales here referred to; and I believe if grey iron be carefully examined, it will be found to be made up, not of iron and graphite, but of crystals aggregated together, and containing carbon and iron chemically combined. When iron is acted upon by dilute acids, as shown by Calvert, the carbonaceous matter left possesses the same form, and occupies the same bulk, and, in fact, has the same appearance in every respect as the iron from which it has been obtained.

But, for the sake of argument, we will suppose that in grey iron the carbon is really as graphite; and here at once a difficulty meets us. How is it that grey iron is more fluid than white iron? In grey iron we have almost a pure iron (which is very difficult to make fluid at all) merely mixed with carbon. In white iron, on the contrary, the carbon is chemically combined, and we all know how much more fluid melted carbide of iron is than iron free from carbon. How is it, too, that the graphite does not separate when the iron is in the fluid state? The graphite itself is infusible, and its specific gravity much lower than the iron in which it floats, one would think that it would separate from the iron and rise to the surface. There are those who answer these questions by saying that iron is capable of dissolving graphite when it melts, and again liberating this graphite when it cools, while others say that a carbide of iron is formed when the iron melts; this carbide is again decomposed on cooling.

I think I can prove, that neither of these explanations can be correct, or, indeed, any other where it is assumed that the carbon exists in the two states, combined and uncombined. First, let us see how far the theory that the graphite, when the iron melts, is converted into a fluid carbide, holds good. Before doing this, however, let me draw attention to the fact, that iron made from the same stone, and under nearly the same circumstances, whether white or grey, contains about the same total percentage of carbon. For instance, the carbon determined by combustion in three samples of grey and three of white iron gave the following results:—

	Grey.	Average.	White.	Average.
Carbon	3·94	3·91 per cent.	= 3·86	= 3·87 per cent.
„	3·92		= 3·85	
„	3·88		= 3·95	
Difference	. . .		·04 per cent.	

We will assume, now, that these irons are melted. The white is already a carbide; the grey is converted into one by melting. Here we have, then, two irons in the fluid state both containing the same quantity of carbon, yet one more fluid than the other. Let them cool and solidify. How is it that one separates graphite and the other does not? Not only this, but we actually know beforehand which of the two will liberate the graphite, or, in other words, be the greyest. If this theory be correct, surely graphite ought not to be separated in the one case and not in the other.

2. The theory of solution. This, I think, is even more untenable than the one already referred to. Faraday has shown that iron is capable of combining with 6 per cent. of carbon. Very few commercial irons contain more than 4 per cent., and if a portion of this be uncombined, I cannot understand the iron dissolving without at the same time combining with it, much in the same way that a solution of chloride of iron, and containing an excess of iron, will dissolve more iron by uniting with this iron to form more chloride.

There is an experiment mentioned by Carey, I believe repeated by Wylde, and confirmed by myself, where a little sulphide of iron is added to melted grey cast iron; the iron immediately changed to white, with the liberation of graphite, which rises at once to the surface of the iron; and I hold that if this graphite had been merely mechanically mixed, and yet unable to separate, separation would not have occurred on the addition of sulphide, for the quantity requisite is not sufficient to produce any material change in the physical properties of the iron while in a fluid state.

We will now look at these questions, assuming, first, that there are two carbides of iron, and that cast iron is a mixture of the two with an excess, perhaps, of metallic iron, or of iron alloyed with silicium, calcium, manganese, &c. The one carbide is grey and soft, the other white and hard, and for reasons explained hereafter, we must suppose the grey to be a higher carbide than the white. We can now easily account for the non-separation of the graphite when grey iron is melted, the grey appearance being due, not to this substance, but to a fusible compound of carbon and iron. But it may be said that graphite does separate when the grey iron is melted. Admitted; but how small a percentage of the total carbon present separates in this manner; and this quantity can be accounted for as resulting from the decomposition of the grey carbide; in fact, this brings us to one of the principal properties of grey iron—viz., its instability. Like some of the complex compounds known in organic chemistry, very slight changes are sufficient to effect its decomposition. This is shown by the liberation of carbon when a little sulphide of iron is added to it while in the melted state, also by its non-production, excepting when the furnace is in the very best working condition; very sudden changes of temperature, too, may effect its decomposition. In many of their properties the grey and white carbides of iron may be compared with the two compounds of carbon and hydrogen C_2H^6 and C_4H_4. How much more stable is the lower carbide than the other; and how readily is the latter decomposed with liberation of carbon, and formation of the less highly carbonized compound.

For the purpose of testing some of these views by experiment, I broke four pieces from a pig of very grey iron, and putting three of these in separate plumbago crucibles, each crucible was covered and coated with fire-clay, and then put into a wind furnace, which was gradually urged to a white heat. The fire was then allowed to burn out, and one of the crucibles removed, which was labelled No. 1. The fire was again lighted and urged, and again allowed to cool, and another crucible was then removed, and labelled No. 2. The third was again treated in a similar manner, and then labelled No. 3.

My object in melting in carbon crucibles was to prevent access of air to the melted iron; if any air did succeed in passing through the crucible it would be deoxidized by the carbon of the crucibles.

The button of iron found in No. 1 crucible was coated on the outside with "keech," or kish, as the graphite is generally called. When the button was split, the fracture showed it to be "No." 3 iron.

The button of iron from No. 2 crucible had less graphite on the outside, and, judging from the fracture, it might be called "No." 4 iron.

The button from No. 3 crucible was "mottled," or "No." 5 iron; it was quite free from graphite on the outside.

Thus, by melting "No." 1 once, "No." 3 iron was formed; melting a second time, "No." 4 iron; and a third time, "No." 5 iron.

I explained these changes by supposing that in the first melting a small quantity of the grey iron had been decomposed and a little graphite liberated; in the second melting more graphite separated, but the graphite liberated from the first melting had again united to form the white carbide; in the third melting all the graphite which had previously separated again combined, and "mottled" iron resulted.

I afterwards determined the carbon in the buttons of iron, and the results obtained appear to confirm the above views.

They were as follows:—

Iron before melting, carbon	= 3·93	per cent.
1st melting	= 3·86	„
2nd „	= 3·90	„
3rd „	= 3·95	„

The low results obtained in No. 1 is accounted for by the graphite liberated in melting. In No. 3, the graphite had again combined, hence this discrepancy is not seen.

Another fact which seems to support the view that the carbon in grey iron is chemically combined is the loss of carbon in the form of volatile carbides of hydrogen; when iron is acted upon by acids, no matter how grey the iron may be, or how large the crystals, there is always some loss in this manner, besides a liquid oily substance formed, which floats on the surface of the acid.

In conclusion, many writers mention the fact, although I have never tried the experiment myself, that by exposing a bar of wrought iron to a high temperature in a current of coal gas, it is impossible to convert it into grey iron. Now, if grey iron contains large flakes of graphite disseminated throughout its mass, I would ask how these flakes can possibly enter the pores of the bar and get into its interior in an experiment of this kind? I can understand the outer coating of iron acting as carrier of combined carbon in the inner portion, and by this means the bar of iron increasing in size and assuming a crystalline form; but I cannot understand a flake of graphite being first formed on the outside, and then forcing its way into the interior, changing the properties and form of the bar.

WORKING EXPENSES OF FIRE-ENGINES IN AMERICA.

THE Amoskeag Manufactory Company publish the following statement which is sufficiently interesting:—

In regard to the cost of running a steam fire-engine many people have very wrong impressions, being led, by the reports of the cost of maintaining them in some large cities when they were first put into service, to suppose that the expense must be very great in all cases. In these cities a regular "fire-brigade" is employed, and the extinguishment of fires is a daily business, and the number of men necessary to work an engine are constantly employed and paid. But even here, as shown by the reports, the use of steam-engines has reduced the the running expenses of the fire department. But in cities of 25,000 inhabitants, more or less, where fires occur perhaps not oftener than once or twice in a month, the expense of maintaining a steam fire-engine is very much reduced; in fact, a steamer in such a city can be run at a less expense per annum than the usual cost of main- taining a hand-engine.

In the city of Manchester, N.H., the fire department consists of three steam fire-engines. We append below the expense of running these engines one year, taken from the city report, and the expense of running a hand-engine for the same period. The cost of repairs is found by experience to be no greater on the steam fire-engines than on hand-engines. The first steam-engine, which has been three years in service, has not required a cent. to be expended upon it as yet.

A steam fire-engine company is composed of fourteen men, all told, one of whom, acting as a driver and steward, is constantly employed, remaining at the engine-house with a pair of horses always ready to run out with the engine in case of an alarm of fire. The other members of the company have other employments, and turn out only on an alarm of fire.

STEAM FIRE-ENGINES.

		dols.
"Amoskeag,"	Expenditures	864 32
"Fire King,"	"	855 78
"E. W. Harrington,"	"	496 09

The above expense includes pay of members, team expenses, cost of gas, wood, coal, and all necessities incident to service.

The "E. W. Harrington" is a second-class engine, stationed in the outskirts of the city, and was run cheaper from the fact that no horses were kept for it by the city.

A first-class hand-engine company is allowed to number, all told, fifty men, and the members of the company are paid as follows:—

FIRST CLASS HAND-ENGINE COMPANY.

	dols.
1 foreman	35 00
1 assistant forman	28 00
1 clerk	28 00
1 steward	68 00
46 men, at 18 dols. each	828 00
50 men. Total	987 00

By this it will be seen that in a city like Manchester, with 20,000 to 25,000 inhabitants, a first-class steam fire-engine can be run at an expense not to exceed that of a first-class hand-engine, while in service it will do at least *four times* the work.

In the city of Boston, the comparative cost of running the two kinds of engines is as follows—viz:—

STEAM FIRE-ENGINE.

	dols.
1 engineer	720 00
1 fireman	600 00
1 driver	600 00
1 foreman of hose	150 00
3 hosemen, at 125 dols. each	375 00
7 men	2445 00
Keeping of 2 horses	315 00
Total	2760 00

HAND-ENGINE.

	dols.
1 foreman	150 00
1 assistant foreman	175 00
1 clerk	125 00
1 steward	125 00
3 leading horsemen, at 125 dols. each	375 00
33 men, at 100 dols. each	3300 00
40 men.	4200 00

Here the engineer, fireman, and driver are constantly employed, the horsemen have other employment in the neighbourhood, but all the company sleep in the engine-house.

When a steam fire-engine is drawn to a fire by the men composing the company, the running expenses are of course no greater than they would be if the same company used a hand-engine.

ARE SCRAPED SURFACES INDISPENSABLE?

IN stating this question as broadly as we have done, we disclaim at the outset any intention of dispensing utterly with scraped surfaces, or of erasing from the vocabulary of mechanical technicalities this detail of the workshop. The doubt has arisen in our mind whether much of the time and elaboration expended on scraping iron surfaces might not, without injury to the work itself, be omitted. The value of a positively correct face on a valve seat or on the V-shaped ribs of a slide lathe or planer, is undoubtedly great when it is well done, but when poorly executed the utility of it is, to say the least, questionable. We make the unqualified assertion that not one man in twenty is competent to finish a truly scraped surface. Scraping iron down to a perfect face is an art by itself, and comparatively little attention, so to speak, has been given to the subject in this country. The common method in use is to take an old file of any kind (except round or square), flatten its end out like a chisel, grind it up square on the stone, and then "grub" away on the iron wherever the workman sees fit. The chances are that previous experience has not fitted the operative for this branch of his business, and he mistakes a shade on the iron for a bearing and makes a depression still deeper by misapprehending the "situation." Of course the fallacy of attempting to make a true face in this way is manifest to every one familiar with the subject. It would have been far better to have saved time wasted in such attempts and trust to good planing and attendance in future to rectify inaccuracies.

The better way to make a scraper is to form it like a Venetian stiletto, or, more familiarly, after the model of the section of a beech nut; that is, to have the blade triangular in section, and approaching concavity. With such an instrument, properly tempered, ground, and sharpened, the finest work can be produced. A flat-faced scraper is an abomination, and only fit to dig holes or to rough out the work for the triangular scraper; it is apt to make "chatters" in the surface, and when these occur we may bid a long farewell to any fine work without filing them out—a very pretty task to undertake after something like accuracy has been attained. Most scraped surfaces are nothing but a combination of scratches, shining blotches, and untruth; and while they are a waste of time to execute, they add nothing to the mechanical value of the work. We may fairly question whether valve-seats up to 180 sq. in. of area, say 15 in. by 12 in., are benefited by scraping. In some locomotive-shops in this country it is the practice to plane the valve-seat so that the tool-marks on it run in one direction, and place the valve so that similar marks cross the seat at right angles, and to set the valves running in this way without further adjustment. The results observed are that in a few days the valve has made a seat for itself that is far more durable than if it had been badly scraped. We do not go so far as some persons and assert that a scraped valve-seat is a positive injury, insomuch that the pores of the iron are filled with an impalpable dust that works out to the detriment of the engine in future; this theory is very finely drawn, although it may be partly sustained by facts. A finely-finished mirror-like surface on a valve-seat or lathe shears is indubitably of great value, and we must, in common justice, give credit to English workmen for great skill in this particular; in general they far excel our own workmen.

There is no reason whatever to interfere with the execution of a finely-elaborated scraped surface in our own shops; but our observation convinces us that time spent in doing such work as we have seen, might be better employed in some other way.—*Scientific American.*

PHOTELECTRIC ENGRAVING.

ONE of the most remarkable, if not important results of modern science, is the power of producing an engraved copper-plate without the direct use of instruments. A plate, in fact, which is really an admirable photograph, capable of producing thousands of copies, which resemble ordinary sun pictures in nothing save minute beauty of detail.

It is needless to say that the attempt to cause the image cast by a lens within a camera to register itself on metal or wood in such a manner that impressions in ink might subsequently be obtained, is by no means new; and judging from a specimen engraving taken by Dallas's process which has been laid before us, this desirable end has been obtained at last with considerable success.

Mr. Dallas has addressed a letter to the Society of Arts on the subject:—

"In consequence of the very questionable protection afforded by the patent laws, I deem it advisable at present not to publish the details of my process.

"I can produce, in a period varying from one to three weeks, an engraved plate from a photograph. In this plate, that which constitutes the essence of the photograph and the despair of hand labour —*fac-simile* even to minute and almost microscopic detail—shall be present. To attain this result, all that I require is a good reversed negative (easily produced by reversing the glass), and a positive print merely fixed with "hypo," not toned.

"The methods which have hitherto given most promise are the bitumen process, photoglyphy, and photogalvanography. The other processes of photolithography and photozincography, from their very nature, cannot rival the richness of plate printing. The bitumen process and photoglyphy are essentially etching processes, and involve much hand labour and consequent loss of fidelity. Photoglyphy is the least satisfactory of the two, as the etching ground employed is of a very delicate nature, and the photographic chemical, bichromate of potash, has the unfortunate quality of destroying detail, the longer it is submitted to actinic influence.

"The most important step in advance was photogalvanography. This process came into my hands when in a most crude and impracticable condition, and after it had been given up as useless by others. By much patient labour I succeeded in making it practical, and the process has ever since been worked with the improvements which I effected. I was not permitted to reap the fruit of my labours, and after a considerable sum had been expended, by my then partners, to develop the process in a direction to which it was wholly unsuitable, the process has been almost abandoned.

"Photogalvanography, like photoglyphy, depends on the peculiar action of bichromate of potash, in combination with gelatine. In this lies its weakness. It loses detail—the more so as it requires a very long exposure, sometimes upwards of six hours, and then without any certainty that the right exposure has been attained. There are constantly numerous failures from this one cause alone.

"I experimented long with this process, and found that the result was due to chromic acid. In other words, that with a composition merely of chromic acid and gelatine, a raised image with granulation could be produced. From this raised image the electrotype plate was subsequently made. Independently of the loss of detail, and the uncertainty in the exposure—both defects inherent in the process—the granulation was of a peculiar zigzag and wiry character, which was of great value in the vigorous parts of the picture, but became broken or unconnected in the half-tones and fine details. This led to a pretty free employment of the graver and roulette, just in the very parts which made hand labour expensive. The process, indeed, was never capable of the high flight which was attempted, and, as I predicted, it broke down. Where expense was no object, the graver was a great assistance, but it lessened the value of the *fac-simile*.

"In photoglyphy and photogalvanography, the results are obtained from a positive impression.

"It was after experimenting some time with photogalvanography that it occurred to me to strike out in a different direction. Any one acquainted with engraving is aware that acquatint and "chalk," or stippling, produce fine grain, half tones, and detail. The problem I set myself was how to imitate this combination. The acquatinter employs common resin dissolved in spirits of wine. This poured over his plate evaporates, and leaves numerous globules of resin attached to the surface. The size of these globules depends on the proportion of resin to spirit. When the acid is put on the plate the resin acts as a resist, and a tint is produced in the intermediate parts. If the plate were now electrotyped before the removal of the resin, and a print taken from the electrotype, the resin parts would give a kind of stipple or "chalk" marks, interspersed with tint. It is something similar to this which I have succeeded in imitating, with peculiarities *sui generis*, by photography and the electrotype. I can also, as it were, modify the size of the

dots, obtaining them so fine as to carry almost microscopic detail; but if too fine there will be deficient depth in the dark. In this as in all things there is the happy medium, and this I believe I have secured. I commence with the negative. This should be reversed. From the negative a positive proof is taken; this I prefer not toned but merely fixed in the sepia colour by the "hypo." I cover the negative, which must be varnished with a material from which I obtain the latent positive. This latent positive I turn by a simple process into a suitable negative, and it is with this negative that I subsequently manipulate. I can time the exposure to a nicety, a few seconds over or under making an inappreciable difference. The excess or deficiency must not, however, extend to minutes. If necessary I can electrotype direct upon my material; but as this might lead to the discovery of part of my process, I prefer to make a different kind of matrix."

MANCHESTER STEAM BOILER ASSOCIATION.

At the last ordinary Monthly Meeting of the Executive Committee of this Association, held at the Offices, 41, Corporation-street, Manchester, on Tuesday, July, 28th, 1863, William Fairbairn, Esq., C.E., F.R.S., in the chair, Mr. L. E. Fletcher, chief engineer, presented his monthly report, of which the following is an abstract:—

"During the past month there have been examined 324 engines and 450 boilers. Of the latter, 17 have been examined specially, 11 internally, 55 thoroughly, and 367 externally; in addition to which 3 of these boilers have been tested by hydraulic pressure. The following defects have been found in the boilers examined:—Fracture, 8 (2 dangerous); corrosion, 16; safety-valves out of order, 9 (3 dangerous); water gauges ditto, 2; pressure gauges ditto, 8; blow-out apparatus ditto, 37; fusible plugs ditto, 2; furnaces out of shape, 4; over pressure, 1 (dangerous); deficiency of water, 1 (dangerous); blistered plates, 3; total, 110 (6 dangerous). Boilers without glass water gauges, 2; without blow-out taps, 38; without back pressure valves, 41.

"It is gratifying to find that the number of 'thorough' examinations of boilers, though not high during the past month, is steadily increasing. During the month ending June 26th last, as many as 104 were made, in addition to 12 'internal,' and 10 'special'—making 126, independently of the ordinary 'external' examinations. This number is a greater one than has been reached in any previous month.

EXPLOSIONS.

"One explosion has occurred during the last month, of a very fatal character, to an ordinary mill boiler of the two-flued 'Lancashire' class, by which 10 persons were killed and four others injured. This boiler was not under the inspection of this Association.

"The dimensions were as follows—length 30 ft., diameter of the shell nearly 7 ft. 6 in., and that of the furnace tubes—which were parallel throughout, and not strengthened by any hoops or flanges—2 ft. 8 in.; the thickness of the plates in the shell and tubes, seven-sixteenths, in the flat end plates half an inch, each of them being strengthened with three gusset stays, secured with double angle irons.

"The longitudinal seams in the shell were not laid in line, but disposed so as to break joint. The age of the boiler was about two years. It had not been tested by hydraulic pressure.

"The boiler had been fitted with a single lever safety-valve, the valve being enclosed in a box bonnetted over, from which the waste steam escaped through a discharge pipe, carried through the wall of the boiler-house. It had also been fitted with a glass water gauge—a feed-check and back-pressure valve combined, fixed to the front end plate, a little below water level—a blow out or mud tap, and a steam pressure gauge, of the dial class; but the boiler had no tap for fixing an indicator, so as to check the accuracy of the gauge, and ascertain the actual working pressure with the steam up.

"The boiler was rent into so many fragments by the explosion, that it was completely destroyed, while considerable damage was also done to the surrounding property. Both the furnace tubes were torn away from the end plates, as well as separated into two pieces, dividing at one of the transverse seams at the middle of their length. Three of these lengths, weighing upwards of a ton each, were blown over a row of cottages, one alighting on the first floor of a dwelling beyond, having broken through the roof in its fall, the other two lengths falling at intermediate distances between these two rows of buildings; while the fourth fell on a cottage, carrying in the roof. The safety-valve weight, which was a ball of about 8 in. diameter, was shot upwards, and on its fall, broke through a roof of a third cottage. The shell of the boiler had been torn up into so many small pieces that it was difficult to trace the course of the rents, and to determine where they had first commenced; but it may be remarked, that one of them ran through the manhole, which was not strengthened as it should have been by a substantial mouth-piece. These fragments of the shell lay scattered near the original seat of the boiler, while some were buried under the ruins. The end wall of the mill was blown down, and the various floors laid open, while the engine was completely buried in the *debris*. The chimney was gashed by a large rent, running up it for half its height, and stood tottering over the old seat of the boiler, so that approach was dangerous; while the ground surrounding was covered with bricks, and the ruins of the injured buildings. But it is difficult to convey an adequate idea of the ruin that had been produced.

"The cause of the explosion has twice been investigated before a coroner's jury, conducted in each instance by a different coroner on account of the localities in which the deaths occurred. Scientific evidence was given in each case. At the first trial, one scientific witness gave it as his opinion that there were no traces of there having been any deficiency of water, but that the safety-valve had been deranged and inoperative; while at the second trial, another scientific witness thought that the safety-valve had worked quite 'glibly,' and that shortness of water had caused the explosion. A verdict of accidental death was brought in in each instance.

"With regard to the explosion having arisen from shortness of water, it was given in evidence at the inquest that the gauge-glass was blown through, and plenty of water observed shortly before the explosion happened: the correctness of which was borne out by subsequent examination, since the flues were found to be coated with incrustation which overheating, had it occurred, would have disturbed; while, in addition, the furnace-crowns could not have retained their shape as they did, had the water been low.

"As to the explosion being due to excessive pressure consequent upon the defect of the safety-valve, it is true that the spindle of the valve was bent, but it is a matter of opinion whether this did not become so subsequently to the explosion, and was its consequence rather than its cause. At the time of making my own examination, which was done immediately on the explosion being reported, there was no opportunity of seeing the safety-valve, since it was in the hands of the jury who were then engaged on the inquest—but I am informed, on good authority, that the injury was such as could not have occurred to the valve in regular work, while it was known to have been previously in good order.

"But, apart from the condition of the safety-valve, there are other considerations affecting the view that the explosion was due to excessive pressure alone. There was no evidence to prove that the pressure exceeded 60 lb. per square inch, and neither that nor twice the amount would have rent the shell had the material and workmanship been good; while from the fact that the flue-tubes were not collapsed, and the shell was rent into fragments—although the latter should have resisted twice the strain of the former—it is clear that the explosion did not result from simple over pressure.

"It cannot be doubted that the plates were of very bad quality, one of them in the shell, situated at the top of the external flue, had fractured through the solid when the boiler was at work a few months since, while it is reported that one of the scientific witnesses who gave evidence at the inquest stated—that merely with the blow of a brick he had broken off a piece of plate about 15 or 16 sq. in. in area, and seven-sixteenths in thickness. The cast-iron nature of the plates rendered them less adapted to withstand the tensile strain of the shell than the compressive one of the furnace tubes which therefore accounts for the shell having been broke into pieces, while the furnace tubes were uninjured, except by the effects of the explosion itself.

"Such is the simple cause of this explosion. The evidence given at the inquest, as well as the examination of the furnace-crowns, forbids the conclusion that the explosion was caused by a deficiency of water; while, further, the fact that the shell, which should have been stronger than the tubes, rent into a number of small pieces while the tubes did not collapse, shows that the explosion was not due to excessive pressure, but to the defective quality of the plates of which the boiler, on examination, was found to have been made."

"In conclusion, the attention of our members may be specially called to the following points:—

"The contradictory nature of the evidence too frequently admitted at coroners' inquests as to the cause of boiler explosions, of which the case above is an illustration.

"The short-sighted economy of purchasing low-priced boilers, erroneously termed 'cheap,' which leaves the maker no alternative but to use plates of inferior quality, a practice not only detrimental to the interests of the steam user, but also unfair to the honest boiler-maker.

"The importance of having all boilers thoroughly tested with dydraulic pressure; this had never been done with the boiler under consideration; had the test been applied, there can be little doubt that the inferior quality of the plates would have been detected, and the explosion prevented."

L. E. FLETCHER, Chief Engineer.

TO CORRESPONDENTS.

G. G.—We will try to let you have all the particulars you request next week.

W. P. (Manchester.)—Willow or alder seems to be more suitable for millstone bushes than any of the harder woods; but why not employ the regular hemp packed stuffing-box, which you will find in every respect superior?

BOILER (Newcastle).—The angle iron rings should be put on at distances of every 10 ft., or thereabouts, on the internal flue. They are seldom welded up, more frequently being made in halves so that when put in place they may butt well again each other at the ends. The complete rings should be an inch greater in diameter than the outside of the flue; washers being provided, through which rivets pass, so that the water may circulate freely between the flue and the ring.

P. B. (Glasgow).—Your steam-pipe is greatly too small; replace it by one double the diameter, carefully clothed.

C. Y. (Brighton).—It seems to be an established rule that the air-vessels of fire-engines can scarcely be made too large.

RECEIVED.—C. W.—E. B. D.—M. O.—W. L. and Co.—J. W.—T. B.—C. F. and Co.

THE STEAM PROBLEM.

HALL'S PATENT SECTIONAL DRUMS AND ROPE FOR STEAM CULTIVATION.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—The diagram on the next page is intended to represent my steel link chain rope passing round two drums, each under a 6-horse power traction engine, working on the opposite headlands of a field in the direction shown by the arrows, for the draught of cultivating implements.

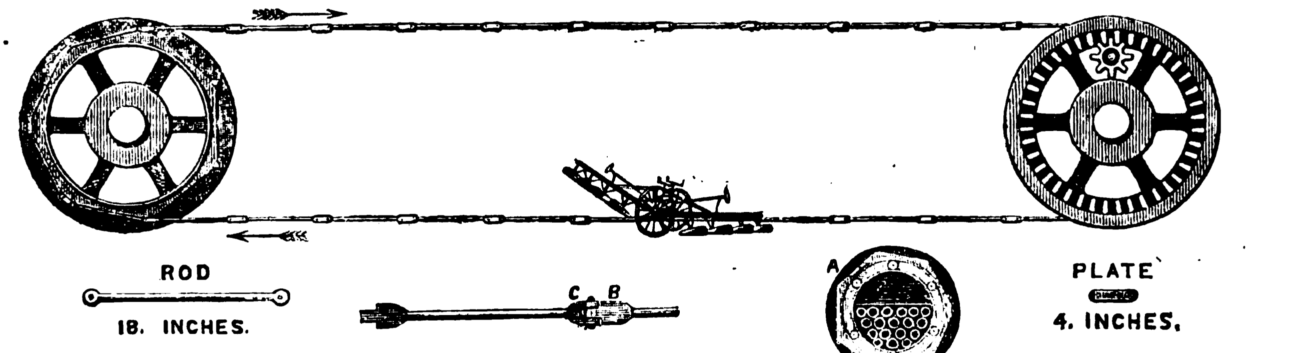
For this purpose, no unity or simultaneous action of two engines has hitherto been practical. We saw at the Worcester Royal Agricultural Show the two very effective 12-horse power engines of Mr. Fowler acting alternately, and the second prize engines of Savory and Son also acting alternately, no means having been devised for uniting their powers.

My rope and drums being a piece of elongated gearing, enables me to use, not two 12-horse power engines, as the above-named gentlemen did, but two of 6-horse power acting together, the united force of which is equal to all heavy land tillage, and by their light, portable, and diminished capacity and consumption of fuel, are better adapted to the other requirements of the farm for thrashing, chaff-cutting, &c.

A represents my sectional drum around the boiler in place of the circular drum and wire rope, as used by Messrs. Savory and Son, and patented by me in February, 1859. C B is another form of rope that will pass around it; but I prefer the plates.

I think it will be readily admitted that a rope

HALL'S PATENT SECTIONAL DRUMS AND ROPE FOR STEAM ENGINES.



formed of ½-in. solid steel rods riveted together, has a superiority over one composed of fine steel wires woven together, which at best is a delicate fabric, and soon destroyed by friction, rust, and unequal [illegible] in in passing over a gritty soil and small drums.

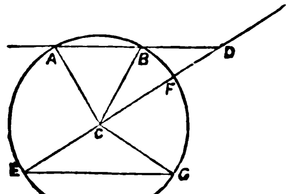
The above system was shown in action at Worcester during the three days' show, and the ploughing (Plot No. 6) was acknowledged to be superior to the other work done, though my engine and tackle had never been at work before, but were exhibited in an incomplete state, rather than miss the opportunity altogether.

I remain, Sir,
Your most obedient servant,
COLLISON HALL, Sen.

Prince's Gate Dairy Farms,
Near Brentwood, Essex.

TRISECTION OF AN ARC.

SIR,—The trisection of an arc or an angle is generally considered a geometrical *crux* of the same character as the construction of a square equal to a circle, of which I sent you a solution lately. The other problem may be solved with equal facility, and by means exactly analogous to the recognized method of drawing an ellipse by a point on a stick of which the ends slide along two straight lines at right angles—or indeed any angle—to each other.



Let AE be the arc, or ACE the angle, to be trisected. Draw the straight line ECFD projecting beyond the circle. Take a straight stick, with the length of the radius BD = AC marked off from one end, and slide that end along FD, keeping the stick on A, until B coincides with the circumference; then BF will be = $\frac{AE}{3}$, or BCF = $\frac{ACE}{3}$.

PROOF.—Draw EG parallel to AB; ∴ BG = AE, and GED = ADE = BCD, because CB = BD; and FCG, the angle at the centre, = 2 FEG, the angle at the circumference, = 2 FCB; ∴ BCF = $\frac{BCG}{3} = \frac{ACE}{3}$.

It is right to add that this proof, though not the construction above, is taken from Mr. Potts's Euclid, p. 162, 5th edition. If the angle to be trisected exceeds 135 deg., this construction becomes impossible, because then BD becomes a tangent. In that case, bisect the angle first, and then trisect it, and double the resulting angle.

E. B. DENISON.

INDIAN RIVER STEAMERS.

SIR,—I read with interest, in your number of July 3, the report of Mr. Leys' Paper on Indian River Steamers, read before the Scottish Shipbuilding Association, March 2, 1863. In it I find the following:—The Indus Flotilla Company had a steamer built on the Thames by a celebrated builder, and tried on that river. Her dimensions were:—Length, 200 ft.; beam, 38 ft.; and depth of hold, 8 ft. She was propelled by a condensing three-cylinder oscillating engine, two of the cylinders being below and the third above deck. At her trial on the Thames she attained a speed of 13 miles per hour with 688 indicated horse-power; her draught of water was 1 ft. 11 in., and her immersed midship section 70 ft."

Immediately after he says:—"There were other six steamers built from this model one, and, from my last account, only one of them had been tried. The results were so unfavourable that not one of them was taken off the contractor's hands after being put up at Kurrachee, the Company having purchased some of the boats belonging to the East India Company, and are carrying on their trade with them."

From these two statements, it would be natural to infer that the "other six," as well as the "Stanley," were built by the same celebrated builder. Such is not the fact. I was engaged in building the "Stanley," which, as Mr. Leys states correctly, went 13 miles an hour on the Thames, drawing only 23 in. of water, and in the shallow water of the Indus, 10 miles an hour—a performance admitted to be the greatest ever obtained there.

I may also add that on the Thames she towed a collier brig, with 350 tons of coal on board, at the rate of 9 miles an hour, her draught being, as above, 23 in. These results, I think, show her to have been remarkably successful. The "other six" vessels, which Mr. Leys asserts were failures, were neither built nor engined by the builder of the "Stanley," nor do the engines and boilers at all resemble the three-cylinder engines and boilers of the "Stanley," which continues to maintain her speed and power in water where none of the others have yet been able to make a single voyage. The author may have been misled by the fact that competing tenders were taken for exact copies of the model boat, the "Stanley;" but the tenders accepted were those of parties who professed themselves able to make great improvements on the machinery and boilers of the "Stanley," which improvements consisted in an entire abandonment of the model in the construction of those vessels of which Mr. Leys truly says the results were so unfavourable that not one of them was taken off the contractor's hands.

It is true the "Stanley" broke down from the failure of a piston-rod; but this accident resulted from the owners not sending out a spare one; they therefore continued working the vessel after they discovered a flaw in it. The vessel which Mr. Leys describes as suitable for shallow rivers, is a description of the "Stanley" with some modifications which I think are not improvements. He says truly, that "light draught is of the utmost importance combined with strength and moderate speed."

It requires very little proof to show that this can be done best by making the vessel as short and wide as possible. In two rectangular tubes of the same length and depth the area of metal in the cross section must be the same for the same strength; hence the weight per foot must be the same, whatever the width; but in order to get the same displacement at the same draught, Mr. Leys must lengthen his vessel to 250 ft., or one-fifth of the whole length; but since the strength varies inversely as the length, it is obvious that he must add one-fifth to the sectional area; therefore, the long, narrow ship of equal displacement and strength weighs one-fifth more per foot than the short wide one—that is, if the iron hull of the long narrow one weighs 100 tons, the short wide one weighs only 70 tons.

The short wide ship will also steer more quickly than the long narrow one—a not unimportant matter where the navigation is difficult.

The arrangement of barges which Mr. Leys advocates is the same in all respects as that provided for in the "Stanley."

The relative merits of high and low pressure engines for such vessels I cannot enter into now, for I fear I have already trespassed too much upon your patience; but the subject of light-draught steamers is an interesting one.

My principal object in writing is to point out that the "Stanley" was eminently successful as regards her speed and power of navigating the river Indus, and that the "other six," which proved failures, were not built or engined by the builder of the "Stanley," nor was she taken as a model to be imitated. I have also endeavoured to show that the vessel which Mr. Leys proposes is the reverse of an improvement upon the "Stanley."

Yours, &c.,
MORGAN H. DAVIES.

Blackheath-hill, July 27, 1863.

Miscellanea.

The total number of registered steam vessels in the United Kingdom on or before the 1st of January, 1863, was 2,192, the amount of registered tonnage being 535,596, and the amount of gross tonnage, 810, 538.

A large cylinder has been constructed at the Caledonian Foundry, Kilmarnock, by Mr. Andrew Barclay, for the Coltness Iron Company. It is 84 in. in diameter, 15 ft. or 16ft. in length, and weighs about 19 tons. It is the largest of the kind ever made in Scotland, and its says much for the skill and enterprize of Mr. Barclay that he has carried off the palm from Glasgow tself in this line of workmanship. This is the second large-sized pumping engine which has been constructed at the Caledonian Foundry for the same company.

The striking feature in the passenger traffic in India still continues to be the enormous preponderance of third class travellers. In the year ending June 30, 1862, there were 61,817 first-class passengers and 299,820 second-class, but no less than 6,447,055 third-class, to whom may be added 342,958 who travelled fourth-class, while carriages of that class were run.

The oldest vessel afloat has just been condemned on the Peruvian cost. She was ninety years old. This was none other than the the whaling barque Maria, of New Bedford, United States. She was the first ship which carried the United States flag in the British Channel after the great revolution.

We learn from the *Army and Navy Gazette* that the first heavy gun made in the royal gun factories with an internal tube of steel instead of wrought iron, was, on its completion a few days since, at once put to its work of testing the Armstrong 100-pounder vent-pieces. This gun has now stood 300 rounds with proof charges, and shows no sign of alteration either in the interior tube or on the outside, a result that must be highly satisfactory to Mr. Anderson, to whom this improvement in gun manufacture is due. It is true that small pieces of steel have been for years past tempered inoil, but the application of oil to temper gun blocks or other large masses of steel was, if not untried, at least not so succesfully carried out as to cause itsadoption.

The screw steamer "Italia," whose trial trip we noticed a short time back, belonging to the fleet of the London and Mediterranean Steam Navigation Company, has just completed her first voyage

to Genoa in 9 days 18 hours, which, considering the very unfavourable weather she encountered throughout the whole voyage, is believed to be the quickest on record. The excellent working of the engines reflects the highest credit on the engineers, Messrs. Maudslay, Sons, and Field, who have fitted two other vessels belonging to that company with similar engines.

It is worth knowing at this time of the year that meat may be kept sweet for a long time in an atmosphere strongly impregnated with acetic acid. The meat is placed on a wooden support, or suspended in a close vessel, on the bottom of which some strong acetic acid is poured.

During the visit of the Lords of the Admiralty to Woolwich Dockyard on Tuesday, they witnessed a series of experiments with the challenge steam fire-engine constructed by Mr. W. Roberts, of Millwall, for the performances of which at the Crystal Palace the patentee has received a special vote of commendation from the Steam Fire-engine Committee, of which the Duke of Sutherland is chairman. The engine, with its pipes and all necessary gear, weighs 1¾ tons, and was conveyed from Millwall to Woolwich by three horses, the whole of the firemen being well accommodated on the vehicle. Steam was got up from cold water in eleven minutes, and the engine was worked up to pressure of 140lb., a powerful jet of water being propelled to a height of 182 ft. Mr. Roberts, is now engaged in preparing an experimental engine for the War Department.

The benefits attending the use of various substitutes for brass or gun metal in bearings is well understood by engineers. Some interesting experiments to decide the relative merits of the patent anti-attrition, and gun metal, took place about a year ago on the London, Chatham, and Dover Railway, and on the London and North-Western. The results are too long for an insertion more *in extenso*, but we have selected the following as sufficiently suggestive. Two patent anti-attrition bearings, weighing 10 lb. 14½ oz., were fitted to a second-class brake carriage on the first mentioned line, on the 23rd of June, 1862. They were removed on the 23rd of August, and weighed 9 lb. 15 oz., thus wearing at the rate of 7½ oz. per month. Two gun-metal bearings fitted on the same day to the same brake weighed 12 lb. 14 oz. On their removal, they weighed 10 lb. 13 oz., having thus lost 16½ oz. during the month. Such facts are sufficiently suggestive of the saving to be effected by the use of such a material.

The following scrap is from Cyrus Redding's "Yesterday and To-day."—It could not be many years after 1720 that the first engine was erected in Cornwall, near the North Downs at Huel Hose, seven or eight miles from Truro, and Mr. Joseph Hornblower was the engineer, who had been sent for into Cornwall on purpose. It may be interesting to know that it required three hands to work Newcomen's first engines. I have heard it said that when the engine was stopped, and again set at work, the words were passed, "snift, Benjy!" "blow the fires, Pomeroy;" "work away, Joe!" the last let in the condensing water. Lifting the condensing clack was called "snifting," because on opening the valve the air rushing through it made a noise like a man snifting. The fire was increased through artificial means by another hand, and all being ready, the machine was set in motion by a third."

We understand that a company is being formed for the purpose of supplying the metropolis with a main trunk underground railway. The suggestion appears to be due to Mr. Charles Baylis, of the Poultry, who has for some time recommended the construction of such a line of railway, to commence at Stratford, in Essex, to proceed to Bow, Mile End and Whitechapel Roads, through the City, down Holborn, Oxford-street, and Bayswater-road, and terminate at Shepherd's-bush, Middlesex. According to Mr. Baylis's suggestion, it is to have four lines of rails, at the least; and is to be furnished with chambers, for the care and keeping of gas and water pipes, telegraph wires, or any other desirable purposes. An opening in the road of say 7 ft. wide, will here and there be left to furnish light and air.

The directors of the Pneumatic Despatch Company state, in their report, that the experimental tube and machinery have been removed from Battersea, and laid underground from the Euston Station of the London and North Western Company to the District Post-office in Eversholt-street. The length of the tube is 600 yds. On the 20th of February last the Post-office authorities intrusted the company with the transmission of the mails. From that date the service of the district has been entirely performed by the company. Thirty trains per diem (Sundays excepted) have been despatched, with perfect regularity, and upwards of 4,000 trains have run without impediment or delay. The time occupied in the transmission has not exceeded 70 seconds. The daily cost of working has averaged £1 4s. 5d., and five times the number of trains could have been conveyed without any appreciable increase of expense. Confirmed in their views by this result, the directors proceeded to carry out the decision of the last general meeting by the issue of a capital sufficient to enable the company to lay a main line of tube 54in. in diameter, with the necessary stations, appliances, and machinery, from the Euston station to the General Post-office in St. Martin's-le-Grand, and forward to Gresham-street. This capital having been subscribed, the directors entered into contracts with Mr. Barrow, of Stavely, Messrs. James Watt and Co., and Messrs. John Aird and Son, for its completion. The length of this tube will be nearly 2¾ miles, and the entire cost, so far as can be foreseen, including the laying, station accommodation, and the necessary apparatus and pumping engines, will be about £65,000. The whole route has been carefully examined and definitely determined. From the active measures taken by the contractors in the preparation of the tubes and engines, the directors hope to commence laying the line at an early date, and will press forward its completion with all practicable expedition. A considerable portion of the further issue of shares has been taken up by the original proprietors and the contractors, and the remainder has been allotted among 76 new shareholders.

We learn, from a Newcastle paper, that Mr. Dryden and Alderman Robinson, two of the River Tyne Commissioners, accompanied by Mr. Guthrie, their secretary, and Mr. Wake, harbour master, Mr. Ure, their engineer, Mr. Messent, the engineer of the Tyne Piers, and other gentlemen, visited the new dredger, No. 5, moored off the New Quay, North Shields, on Friday last. This stupendous machine, which was constructed by Messrs. T. Wingate and Co., of Glasgow, for the Commissioners, was launched into the Clyde on the 1st inst., and left two days afterwards for the Tyne, under the command of Captain Bell. She was accompanied by Mr. Ure, and went "North about," encountering near the Orkneys on her voyage some heavy seas, which proved her to be a good sea-boat. She arrived in the Tyne on the 10th, and was immediately fitted for operation. The Commissioners and officers went down to the new craft at seven o'clock in the evening on board their steamer, and after inspecting the craft and the steam-engines, the order was given to set the machinery in motion. The two ladders, each containing 35 baskets, and weighing upwards of 100 tons, were easily managed by a single man at each pulley, and were let down upon the bottom of the river, and very soon gave evidence of their powers, working without the slightest check from the moment the engine was started, and in the space of little more than an hour filling two of the Commissioners' hopper-barges, one on each side, and each containing 300 tons of mud and water. Mr. Wingate directed the trial of the engines and machinery, which was completely successful. A novelty of the construction is the manner in which the power is communicated by the engine to the dredging apparatus by means of the friction wheels of Robertson, of Glasgow, instead of the toothed or cog-wheels generally in use. The new wheels seem to answer admirably. It is calculated that the new dredger, when in full operation, will raise 10,000 tons of material per day, and we believe we are not mistaken in saying, will be one of the most powerful dredgers in Europe. The engine is of 50-horse power nominal, and is capable of being worked up to three times that power. Each bucket weighs a ton and a quarter, and the ladders are calculated to operate in 30 ft. water, and when working at speed, will each fill a hopper-barge in from 50 to 55 minutes.

The annual congress of mechanical engineers is to meet in Liverpool on Tuesday, the 4th of next month, and its sittings will extend over the Wednesday, Thursday, and Friday of that week. An efficient and active local committee has been formed. Mr. William Clay, managing partner of the Mersey Steel and Iron Works, having been appointed its chairman, and Mr. William Stubbs its secretary. The arrangements have been all but completed, and these are such as to give assurance of a highly interesting meeting. The congress is to assemble each morning in the Concert-room, St. George's-hall, where papers will be read and discussed, after which excursions will be made for the purpose of examining the noteworthy establishments in Liverpool and its vicinity. The steam-tender "Satellite" has been most kindly placed at the service of the committee by Mr. C. MacIver, and the railway companies offer every facility to the members for visiting the various places of interest. The programme of proceedings has not yet been officially announced, but we understand the following, among other places, will be visited, namely:—The Mersey Steel and Iron Works; Messrs. Laird's Shipbuilding-yard; Bibby's Copper Works, at the Great Float; the Dock Board's chain-testing machine; the North Docks. Visits of inspection will also be made to the Plate Glass Works at St. Helen's; Messrs. Pearson and Knowles' Collieries, near Wigan, and to the Kirkless-hall Iron Works; and also to the London and North Western Railway Company's Locomotive Works at Crewe. During the meeting there will be a grand banquet in St. George's-hall, under the auspices of Mr. Robert Napier, of Glasgow, the President of the Institution, and, so far as can be gathered from present appearances, the meeting promises to be highly interesting and successful. The congress last year was held in the Mansion House, London, and was in all respects very interesting.

It appears from a parliamentary return, that the Armstrong guns supplied by the Elswick Ordnance Company to the Government have cost in all £394,660 6s. The guns supplied from Woolwich have cost £445,205 7s. 9d. The Armstrong shot and shell, including fusees, supplied by the Elswick Company, cost £414,194 5s. The shot and shell supplied from Woolwich cost £142,930 8s. 7d.; making a total—which, we may remark, is exclusive of any expenditure which may have been incurred for machinery, alterations, repairs, and fittings required for the manufacture of Armstrong guns—of £1,396,990 7s. 4d.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c., 3421.
BOILERS AND FURNACES, 3430.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 3422, 3428.
SHIPS AND BOATS, including their fittings, 3434.
CULTIVATION OF THE SOIL, including agricultural implements and machines, 3425.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 3443.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 3420, 3424, 3431, 3433, 3436, 3542, 3444, 3445.
BUILDINGS AND BUILDING MATERIALS—*none*.
LIGHTING, HEATING, AND VENTILATING, 3412, 3417, 3427.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 3437, 3439, 3440, 3448, 3460, 3461, 3467.
METALS, including apparatus for their manufacture, 3414, 3426, 3438.
CHEMISTRY AND PHOTOGRAPHY, 3418, 3423, 3429.
ELECTRICAL APPARATUS, 3411.
WARFARE, 3435.
LETTER-PRESS PRINTING—*none*
MISCELLANEOUS, 3413, 3415, 3416, 3419, 3432, 3441, 3446.

3411. F. C. BAKEWELL. *Improvements in transmitting and receiving communications by means of electricity.* Dated December 22, 1862.

We cannot here give space to the voluminous details of this invention. *Patent completed.*

3412. J. MCLEAN. *Improved apparatus or arrangements for obtaining oil and other products from shale and the like bituminous minerals.* Dated December 22, 1862.

The improved apparatus for carrying out this invention comprises a number of cast-iron retorts disposed horizontally, and, by preference, in sets of three to each furnace. Each retort is about 7 ft. 6 in. long, by 3 ft. wide, and 1 ft. 6 in. deep, all as measured internally, of a fair oval form in cross section, and about 2½ in. in thickness. Two of the retorts are disposed within 1 foot 4 in. of each other, and the third is placed in the centre space above them, the three being arched over. The furnace grates are about 3 ft. 6 in. in length by 2 ft. wide, and 3 in. fire brick flags are interposed between them and the retorts to support the latter. The retorts are fitted with doors of boiler plate, which are fixed by cross bars, screws, and levers, and each retort is provided with two outlet pipes by which the dis-

tilled products pass off. The outlet pipes are passed through condensing cisterns provided with feed and overflow pipes, and kept constantly free of cold water, and on leaving the cistern the pipes descend vertically downwards to the lying pipe or main by which the products of the several sets of retorts are conveyed to the collecting tank. A second condensing apparatus is provided for any overflow of gas or vapour not condensed in the first cistern, and at a part of the main before it reaches the collecting tank an outlet is provided for separating the ammoniacal liquid from the oil. *Patent abandoned.*

3413. W. FRANCIS. *Improved apparatus for cutting soap.* Dated December 22, 1862.

In carrying out this invention, the inventor makes a frame of the same length as bars of soap are generally made, and of a width corresponding thereto, in which frame are fixed knives of a peculiar shape, placed at proper distances to cut the soap into pounds, half-pounds, or quarter-pounds, at the will of the operator, the knives being moveable, so as to admit of the soap being cut into only pounds, or, if desired, pounds and half-pounds, or pounds, half-pounds, and quarter-pounds. To give strength to the knife blades, and also to keep them immoveable while they are being used, they are made with a screw at each end; the ends of the knives being square are let into the sides of the frame and then tightened by means of the said screws, which renders the cutting easier. When the cutter is used, a quantity of soap is simply placed in a heap (one bar on another), the cutter carefully placed on the top, then pressed down, thereby cutting through the soap, and leaving it ready to be wrapped up in paper, without the necessity, as a rule, of it being weighed, the frame being so adjusted as not to require it; but it is not solely for the purpose of dispensing with the weighing apparatus, but also for facilitating the cutting up of soap for sale in pounds, half-pounds, and quarter-pounds. *Patent abandoned.*

3414. A. S. STOCKER. *Improvements in rolling iron for the manufacture of tips and other articles.* Dated December 22, 1862.

This invention (which refers to a previous patent, dated March 17, 1862, No. 728), relates to rolling iron applicable to the manufacture of boot heels and toe tips plain on both its surfaces. The patentee produces the iron in two or more bars, and afterwards divides them by the aid of shears or otherwise. *Patent completed.*

3415. G. E. M. GERARD. *Improvements in the fabrication of threads from vulcanized india rubber and the apparatus connected therewith.* Dated December 22, 1862.

This consists in cutting bands or sheets of vulcanized india rubber with little or no waste and great rapidity into threads of perfect regularity, and the ends of which are united by a sort of selvage formed of the edge of the band or sheet. *Patent completed.*

3416. E. B. DANN. *Improvements in goffering apparatus.* Dated December 22, 1862.

This invention consists in forming the bars used in goffering apparatus in two or more parts, or bent at angles, one part of each bar to the next of it, or in series of curves, in place of such bars being straight, round, or flat as heretofore. The patentee forms the bars of various sizes of angular or other section, and in series of the same or varying sizes, corresponding with the form to be produced. *Patent completed.*

3417. R. A. BROOMAN. *Improvements in stoves or apparatus for heating and drying.* (A communication.) Dated December 22, 1862.

This invention consists in the construction of apparatus for heating and drying, in which the air is heated by being caused to circulate in a zigzag direction through a casing surrounding pipes and chambers, in which the products of combustion, from a stove, are made to pass all as hereafter described. The stove consists of a grate, with a dome-shaped casing above it, in communication with a series of chambers one above the other, and connected by pipes, each chamber containing plates for dividing the products of combustion in their passage to the outlet or chimney. The apparatus just described is enclosed in a casing, with division plates alternately fixed to each chamber. Air is admitted near the bottom of the apparatus, and, circulating round and in contact with the chambers, is heated, and passes upwards in a zigzag direction, to be used for heating or drying as required. *Patent completed.*

3418. M. CLARK. *Improvements in treating waste liquors obtained when dyeing Turkey red colours.* Dated December 22, 1862.

In the process of Turkey red dyeing by the new or machine process, a liquor is produced containing water, carbonate of potash, or soda, or a mixture of these two salts, and olive or other oil. Before running off this liquor, sulphuric, nitric, muriatic, or other acid is added. This separates the oil from the potash or soda solution, causing it to come to the surface. The oil is then skimmed off; and the liquor remaining has hitherto been considered waste and runs away to the stream. This invention consists in utilizing this waste liquor, by artificially heating the same in order to evaporate it, and then to crystallize the sulphate, nitrate, muriate, or other salt of potash or soda, depending on whether potash or soda (or a combination of the two) was the alkali used. *Patent completed.*

3419. J. B. DALHOFF. *Improvements in cutting files, and in machinery to be employed for that purpose.* Dated December 22, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3420. C. FARRAR. *Improvements in machinery or apparatus to be employed in treating certain fibrous materials.* Dated December 22, 1862.

This invention has reference to improvements in machinery or apparatus to be employed in the boiling and cleansing of rags or other fibrous material applicable to paper-making or other manufacturing purposes, whereby the said process of boiling and cleansing is more effectually and expeditiously performed than at present, and consists in employing, in connection with a rectangular vessel or boiler charged with water or otherwise, to which heat is applied, an open work cylinder, drum, or cage, mounted horizontally, so as to contain the goods under operation, and to travel or revolve slowly within the same, the open work cylinder or drum being mounted upon short disconnecting trunnion bearings, through the medium of glands or stuffing-boxes, fixed upon the ends of the said boiler, in lieu of a continuous or solid shaft, for the convenience of lifting the same in or out of the boiler, and discharging the contents thereof; employing, also, with the above apparatus for the washing and cleansing process, an open work cylinder or cage, in like manner mounted and caused to revolve upon hollow trunnion bearings, through which water or steam is admitted to the goods contained therein under operation, and in enclosing the same within an outer case or tank, provided with outlet ways or passages. *Patent abandoned.*

3421. C. PIEPER. *A new improved governor for steam-engines, turbines, water-wheels, and other machinery, with valvular arrangements to regulate the speed of the same.* Dated December 23, 1862.

The documents relating to this invention are with the law officers, and cannot at present be seen.

3422. F. PARKER. *Improvements in carriages.* Dated December 23, 1862.

This invention consists—1, in connecting the shafts or front bar directly to the axle by means of steering irons or tension rods connected therewith, thus giving to the ends of the springs liberty to play along the shafts, through the medium of sockets or rings passing round the shaft in connection therewith, instead of at one of the said ends only, as at present; 2, in attaching one end of the springs to the shafts by means of iron clips or bands passing round the same, in lieu of lug plates bolted through the shafts, where it may be necessary to leave one end only of the springs at liberty to play; 3, in the employment of india rubber, gutta percha, or other flexible material combined with metal, instead of being entirely of iron (as at present) for forming or manufacturing the sockets or rings through which the shafts play by the expansion or contraction of the springs when in motion; 4, in placing and fixing the shafts at the sides of the elliptic springs, in place of passing them between the upper and lower halves thereof, when found desirable, the shafts being connected or attached to the ends of the springs by either of the methods herein described; 5, in the employment of springs of substance proportionate to the minimum weight intended to be carried, in connection with auxiliary springs, arranged so as to be brought into play when additional weight is placed on the carriage, in lieu of springs proportionate to the maximum weight (as at present employed); as also in placing the auxiliary springs either within the same or parallel to the ordinary springs, so that, when a certain amount of weight is placed upon the carriage, the ends of the upper halves of the auxiliary springs may be brought together and made to rest upon the lower halves thereof, through the medium of india-rubber pads attached to the ends; 6, in the employment of clips or bands for attaching the upper halves of the springs to the body, and the lower halves to the axle, in like manner, whereby a more effectual method of securing the same is effected than by passing the bolts through the springs as hitherto; 7, in the employment of bearings of india-rubber placed between the body and the upper halves of the springs, as also between the lower halves of the springs of the axle for lessening or checking concussion, noise, and wear and tear when in use. *Patent completed.*

3423. R. A. BROOMAN. *A new or improved colouring matter or dye.* (A communication.) Dated December 23, 1862.

The object of this invention is the production of a new colouring matter for dyeing and printing, which the inventor terms "Imperial Ruby." The colour (the normal tone of which is a cerise, or its derivative shade) is obtained by the combination of fuchsine and coralline, or any other yellow or orange colour extracted from coal. Process:—The fuchsine and coralline are dissolved, together or separately, in methylated spirit, acetic acid, alcohol, or other spirit. The coralline predominates in quantity over the fuchsine; thus, to obtain the normal tone of imperial ruby, the inventor takes, say, three parts of coralline to two parts of fuchsine. These proportions may, however, be varied; any excess of coralline in the dyeing bath tends to produce a yellower cerise, while an excess of fuchsine, on the contrary, imparts a more violet shade; thus, by varying the proportion of one or other of the products, all the graduations of shades of cerise and its derivatives may be obtained. *Patent completed.*

3424. C. A. F. COLLETTE. *A new kind of lace, to which it is intended to give the name of "Collette's" laces.* Dated December 23, 1862.

This invention consists in the reproduction, in coloured silk lace, of all natural, artificial, or fancy flowers, or of any other coloured designs or patterns to be applied to various uses, such as ornamental flowers for state robes, ball-dresses, parasols, screens, fans, and all sorts of articles of the same or other kinds. In order to obtain these various products, the inventor first punctures the model or pattern to be reproduced on cartoons; he then proceeds in the ordinary manner of making common lace, but with as many bobbins of silk of the required colour as may be necessary, that silk known as Alais silk being preferred. He does not restrict himself to that kind of silk, however, as several other materials, such as bobbin, flat core, twist, brass, and iron wire; and other kinds may be used, according to the work required to be done. *Patent abandoned.*

3425. J. PATTERSON. *Improvements in machinery or apparatus for grinding, crushing, cutting, cleaning, and hulling, or shelling various kinds of farm or vegetable produce, also applicable to the crushing or grinding of minerals and other substances.* Dated December 23, 1862.

The present improvements have reference to that class of mills wherein the surfaces between which the substance to be ground or otherwise operated upon, consists of discs placed parallel or nearly parallel to each other, as in the case of a pair of ordinary millstones. The surfaces themselves may consist of ordinary grinding stones, or of steel, or any other suitable material. According to this invention, in place of imparting to the runner a simple rotary motion on its axis, it is proposed to impart a compound or twofold motion thereto, by causing it to revolve round its own axis, whilst at the same time such axis itself is made to describe an orbit round an imaginary axis. By this compound motion of the runner a wrenching or compound action is obtained upon the substances to be ground or otherwise operated upon, in addition to the effect produced by the ordinary motion of millstones or other similarly arranged guiding surfaces. *Patent abandoned.*

3426. E. B. WILSON. *Improvements in apparatus to be employed in the manufacture of malleable iron and steel.* Dated December 23, 1862.

This invention relates to a peculiar construction and arrangement of what are known as atmospheric converting vessels employed in the manufacture of malleable iron and steel, whereby they are rendered more firm and steady under operation than converting vessels of the ordinary construction. According to this invention it is proposed to dispense entirely with the axis, pivots, centres, or trunnions hitherto employed in suspending converting vessels, and to cause such vessels to turn or rotate upon hoops or rockers fitted thereto. *Patent abandoned.*

3427. G. HASELTINE. *Improvements in the mode and apparatus for converting petroleum or coal oil into gas for lighting and heating, the said improvements being especially applicable to lamps and stoves.* (A communication.) Dated December 23, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3428. J. WHITLEY and J. W. BURTON. *Improvements in the construction of the permanent way of railways, which improvements are also applicable to railway wheels.* Dated December 23, 1862.

This invention consists in the application of a packing or cushion of wood, paper, or felt between the connecting plates or fishes for connecting the rails together and the rails. These cushions may be compressed and chemically prepared, as is well understood, to aid in their preservation from the action of damp. *Patent completed.*

3429. S. RUSSELL. *Improvements in stereoscopes.* Dated December 23, 1862.

For the purposes of this invention, the patentee constructs an instrument in the form of a box, of a length, depth, and width suitable for containing, when out of use, a number of stereoscopic slides or pictures. The instrument is closed by a sliding or other suitable cover when out of use, and on the interior and against one side mirrors are fixed. Not only may the top have a moveable cover, but the bottom also may be made moveable, so that when in use a stereoscope may be open both at top and bottom when desired. The lenses or eye-pieces are fitted in apertures in the lower part of the opposite side of the box, this part of the side being suitably inclined to the plane of the mirrors. The stereoscope pictures or slides are, when about to be observed, placed in suitable grooves or holders opposite the mirrors, and on the side where the lenses or eye-pieces are applied, they are held in a position inclined to the plane of the lenses, and also to the plane of the mirrors. By this arrangement no reflector is required to throw light on the picture, but the light falls directly on it so as to illuminate it thoroughly. *Patent completed.*

3430. T. C. HINDE. *Improvements in furnaces or apparatus for generating carbonic oxide.* Dated December 24, 1862.

This invention consists of certain improvements in furnaces or apparatus for generating carbonic oxide, whereby the said carbonic oxide may be conveniently and economically made from small anthracite, or other small coal or coke, as well as from large coal or coke. The said carbonic oxide may be used for heating steam boiler and other furnaces, and for various other purposes. *Patent completed.*

3431. S. HASLAM and A. EATOUGH. *Improvements in machinery or apparatus for preparing cotton or other fibrous materials to be spun.* Dated December 24, 1862.

Instead of one doffing cylinder with card teeth, as hitherto adopted, the inventors employ two cylinders, each mounted with belts or bands of felt, flannel, or other similar material, so as to leave spaces between them. The cylinders are placed in relation to each other in such manner that the belts on one cylinder enter the spaces of the other cylinder, and when revolving motion is given to the cylinders slivers are taken off the main card cylinder the same width as the belts, instead of one wide fleece, as at present. *Patent abandoned.*

3432. G. H. BIRKBECK. *Improvements in instruments for surveying and levelling.* (A communication.) Dated December 24, 1862.

This invention has for its object the arrangement and combination of parts so as to form a compound surveying instrument, to be called a "level-graphometer square," which is capable of executing the various operations which each of the above-named instruments is only capable of performing separately. This improved instrument is composed of a cylinder of brass, or other suitable metal, divided longitudinally with its axis into two equal parts, connected together by a central pin or axis, thus forming two cross-staffs, to each of which "pinicles" are hinged, so as to fold down out of the way when out of use. Between the two semi-cylindrical parts a dial or plate having divisions thereon is fixed and used. When the instrument is employed as a "graphometer," the instrument in this case is mounted, by means of a screw-pin or otherwise, upon a suitable stand or support. When the instrument is employed as a level, it is suspended by a ring attached to the upper end thereof, and it is accurately adjusted perpendicularly by a moveable weight actuated by an adjustable screw attached to the lower end. Sight holes or openings are formed through the

moveable semi-cylindrical part of the instrument, through which the divisions on the dial plate may be seen and read off when required, a fine wire or thread being stretched across each aperture in the direction of the line of sight. Flat plates, connected by a central pin or axis, may be substituted for the semi-cylindrical parts before described, by which the construction of the instrument will be simplified, but its form will not be so elegant. The divisions on the dial plate are in sections of five, or other suitable number of degrees, so that the instrument acts not only as a "square" (which, in other respects, it replaces very advantageously), but it also admits of small angles being taken, as with the "graphometer." *Patent completed.*

3433. J. BROADBENT and J. ROBINSON. *Improvements in machinery for opening and cleaning cotton and other fibrous materials.* Dated December 24, 1862.

The nature of this invention consists in directing currents of air through apertures in the circumference of a toothed drum, or drum with beaters, forming part of an ordinary opening machine, which air not only strikes the fibrous material against the grid, and assists in removing the dirt and other impurities, but also carries the fibrous material forward against the usual wire cages from which it is carried in a fleece, and formed into a lap by the usual lap rollers. The currents of air pass through apertures in a line with the teeth or beaters, and strip the cotton or other fibres off them; the air is admitted through openings in the ends of the drum, and is produced by a fan or by vanes placed within the drum. *Patent abandoned.*

3434. F. N. GISBORNE. *Improvements in the means for indicating the speed of ships at sea.* Dated December 24, 1862.

In carrying out this invention, the inventor employs magneto-electric currents, excited by a soft iron armature revolving before electro-magnets attached to a permanent magnet, and motion is given to the armature by the action of water upon screw fans attached to a shaft, at the end of which the armature is secured, in accordance with the speed at which the apparatus is towed through the water. The currents generally are conveyed through the insulated wires to a step-by-step electro-magnetic indicator, and the number of progressive movements within a given time will thus indicate the speed of the vessel. Sometimes he uses the revolving axis simply to make and break a galvanic current, which, in effect, answers the purpose hereinbefore mentioned. *Patent abandoned.*

3435. A. P. TRONCHON. *Some improvements in the construction of firearms.* Dated December 24, 1862.

This invention consists in forming a hole through the entire length of the stock, so as to communicate with the barrel; this hole is filled up with cartridges. Several means may be employed to facilitate the pushing of the cartridges and their introduction into the barrel. *Patent completed.*

3436. J. S. SMITH. *Certain improvements in looms for weaving.* Dated December 24, 1862.

Provisional protection has not been granted for this invention.

3437. W. C. GALLOWAY. *Improvements in pianofortes.* Dated December 24, 1862.

This invention relates to contrivances or means for modifying or softening the tone of the instrument at the will of the performer. In carrying out the invention, according to one modification, there is provided a kind of curtain or a layer of a suitable soft and elastic material, such as felt, leather, or rubber, which, by the action of a pedal or equivalent mechanism, can be interposed between the hammers and the strings, and which, by modifying the force of the hammers' stroke, will produce the required softening of the tone. The degree of modification of tone may be varied by the pedal or equivalent action bringing the interposed material more or less near to the hammers, so as to offer more or less resistance thereto; or a similar variation may be obtained by the interposed material being more or less tightly stretched. *Patent abandoned.*

3438. W. HENDERSON. *Improvements in obtaining iron and steel from certain ores and residual products.* Dated December 24, 1862.

In the manufacture of sulphuric acid from iron pyrites the residue consisting principally of oxides of iron still contains from 3 to 9 per cent. of sulphur and cannot therefore be used with advantage for the manufacture of iron. When copper pyrites or iron pyrites containing copper are used for this manufacture, the residue contains copper besides a certain proportion of sulphur which renders it still more unfit for the manufacture of iron. By treating burnt copper pyrites by the process for sulphuret copper ores, described in the specification of a previous patent granted to the present patentee dated 20th December, 1859, No. 2900, practically all the copper and sulphur are extracted and a very pure oxide or mixture of various oxides of iron remains as a residue. When found desirable iron pyrites residues containing no copper may be treated in the same manner and a very pure oxide or mixture of oxides of iron will be the result if the pyrites have been originally rich in sulphur. These residues, after treatment by the above process for the extraction of copper, are in a very fine state of division and cannot be used advantageously in a blast furnace for the production of cast iron. They produce little or no slag and pass rapidly through the furnace not properly reduced, choke the furnace, or are blown away by the blast. The present invention relates—1, To means of producing cast iron from these residues or a mixture of these residues with other ores. 2, To a method or methods of obtaining steel from these residues or a mixture of these residues with other ores or other substances. 3, To a method of obtaining malleable iron from these residues or a mixture of these residues with other ores. 4, To a method or methods of obtaining other qualities or compounds of iron from these residues either mixed with other substances alone or in conjunction with other ores. The details are voluminous. *Patent completed.*

3439. W. CLARK. *Improvements in the means of applying the feet in boots and shoes, and otherwise, part of which improvements is applicable to other heating purposes.* (A communication.) Dated December 24, 1862.

This invention relates to an improved apparatus of simple construction to be applied to the heel of a boot or shoe, for the purpose of warming the feet without danger of burning them. The apparatus consists of a hollow metal heel, with a false bottom, which is hinged to a metal sole piece, and serves to contain the charcoal used for transmitting warmth to the foot. The combustion of the charcoal when once lighted is maintained by the admission of cold air, which distributes the heat throughout the boot or shoe. The inventor applies a metal gauze to neutralize the effect of too strong a flame, which would be apt to burn. The lump of charcoal is maintained in position by means of a spring; the parts are also fixed by means of a spring button or pin, which serves for throwing off mud; or a spur may be substituted for the pin above mentioned. *Patent completed.*

3440. H. TWELVETREES. *Improvements in washing machines.* Dated December 24, 1862.

This invention consists in the combination in a washing machine of an endless web or belt, to which the clothes or other materials to be washed are attached, the rollers used having elastic pressing surfaces of india rubber. The endless web is conducted over suitable rollers to carry it down under the water or washing fluid, and upwards and between the india rubber rollers above the fluid. The belt is of a breadth, and conducted so as to traverse the area of the machine. The elastic rollers are situated at one extremity, while at the other extremity is another pair of rollers, the lower one of which serves as a conductor of the web, while the upper one resting on it has knuckles or projections formed on it, and which, by its weight, acts on the clothes in their passage between it and the conducting roller. The heavy knuckle roller may be further pressed down by springs taking effect on its axis. The clothes or other things to be washed may be secured to the web while it is in the machine; or the inventor sometimes makes such endless web to disconnect readily at one point, so as to remove it with the clothes; another web being used and ready charged may be at once introduced into the machine, and the time of the machine thereby economized. *Patent abandoned.*

3441. J. FAIRLESS. *Improvements in apparatus or machinery for milking cows.* Dated December 24, 1862.

This invention consists of an elastic pipe connected with four branches, which fit on to the teats of the cow; the other extremity of the pipe or tube communicates with an air pump, which is contained in the lid of an ordinary milk can, the lid being formed hollow for containing the necessary valves. This air pump consists of a flat disc of vulcanized india rubber, or other suitable material, which is moved upwards and downwards by means of a rod passing out through the top of the milk can, and actuated by a handle. The action is as follows:—The air being exhausted from the pipe or tube, by means of the air pump, the milk runs into the lid of the can, and by means of a valve opening outwards passes into the interior of the can. When no more milk can be got, the extra pressure of the air causes it to pass between the cones which fit on to the teats of the cow, so that they can be easily detached. *Patent abandoned.*

3442. R. LAKIN and J. WAIN. *Improvements in machines for spinning and for doubling cotton, and other fibrous materials.* Dated December 24, 1862.

The first of these improvements is applicable to certain machines for spinning, commonly known as doublers or twiners, in which the spindles recede from and approach to the creel, and consists in improved mechanism for regulating the winding on motion in the before-mentioned machines, when constructed with the screw usually attached to the radial arm known as Richard Roberts's. The second improvement is also applicable to the said machines called mules, and to such doublers or twiners as aforesaid, and consists of an improved arrangement and combination of mechanism whereby motion may be given from a shaft placed below the rim shaft to the scrolls or equivalents therefor, which draw in the carriage, and also to the cams or cam shaft, and to the backing off wheel. This shaft has attached to it a wheel, which receives motion from another wheel attached to the pulley on the rim shaft usually termed the loose pulley. The motion of this shaft when in rotation may be communicated as required by suitable means to the scrolls or equivalents therefor to the cams or cam shaft, and to the backing-off wheel. The third improvement is applicable to the machines called doublers or twiners, and consists in improved means of holding the threads during the operation of winding on in lieu of the jaws and slide usually employed. The fifth improvement, which is also applicable to doublers or twiners, consists in certain means of preventing or stopping the continued rotation of the cops or bobbins caused by the momentum they acquire during the drawing of the yarn from off them by the machine, so that the rotation may cease when the machine ceases to draw off. This the patentees effect by fixing a support or retarding surface, so that each cop or bobbin, or the skewer on which it is placed, falls against or comes in contact with the same when the machine ceases to draw the cop or bobbin, and thereupon the friction created by their contact acts as a break, and stops the rotation. *Patent ompleted.*

3443. E. STEVENS. *Improvements in machinery for preparing dough, and paste suitable for making bread, biscuits, pastry, cakes, and similar articles.* Dated December 24, 1862.

For the purposes of this invention, the patentee employs a mixing vessel, made by preference of sheet metal, galvanized or enamelled, or cast iron may be employed. The vessel is mounted on wheels, so that it can readily be moved from place to place. One of these wheels is a pivot wheel, and has a handle connected with it, by means of which the vessel can be drawn from place to place and readily guided. The bottom of the mixing vessel is made semicircular interiorly, and double, to contain in the space between the two parts warm water to facilitate fermentation. It should be fitted with a gauge and thermometer. In place of using water to warm the mixing vessel, it may be warmed by steam, hot air, or otherwise. In hot climates the mixing vessel will need to be cooled in place of heated. In addition to this mixing vessel he employs a fixed frame, consisting of a bed plate and two standards suitably tied together, and at such a distance apart as to receive the mixing vessel between them, and suitable turn buttons or clamps are provided for securing the mixing vessel in this position. To effect the mixing of the dough or paste when the materials have been placed in the mixing vessel, a horizontal cranked axis or bar, with inclined toothed stirrers upon it, is employed. The toothed stirrers may be made either round or rectangular in cross section, and may be much varied in form. The cranked axis or bar is of such a length as to be able to be placed in the mixing vessel, and it is of such a form that, when caused to revolve, it passes just clear of the sides and bottom of the mixing vessel. *Patent completed.*

3444. J. TAYLOR. *Improvements in engines for carding cotton and other fibrous materials.* Dated December 24, 1862.

This invention relates to mechanism to be used for the purpose of stripping the carded fibrous material from that card cylinder termed the doffer in carding engines, and it consists in the application to the doffers of carding engines of a combination of a roller and concave straight edge or disc. The roller rotates against the concave straight edge or surface, which is pressed slightly against the periphery of the roller for the purpose of giving it sufficient adhesion to take hold of and strip the material from the card surface of the doffer, and carry it past the concave straight edge or surface in the form of an endless fleece. *Patent completed.*

3445. J. and W. LORD. *Improvements in machinery for fluting rollers, used for preparing, spinning, and doubling fibrous materials.* Dated December 24, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3446. J. H. JOHNSON. *Improvements in apparatus for stamping or marking paper and other materials.* (A communication.) Dated December 24, 1862.

This invention relates to a peculiar construction and arrangement of ink stamper for marking papers and documents of all kinds, and for obliterating postage and other stamps, and consists of a rotating die contained in the lower end of a forked frame or holder, within which frame works vertically, by the action of the handle of the apparatus, an inking pad. On the stamp being pressed on to any surface, the pad descends and inks the upper surface of the die, which is provided with the proper type, according to the words or characters to be printed or impressed. A spring is employed for elevating the pad after the pressure of the hand is removed, and simultaneously with the rising of the inking pad a spring arm in connection therewith acts by means of a pin at its lower extremity upon a slotted disc fast on the end of the axis of the disc, and imparts on rising a partial or semi-rotation to the die, so as to bring the other surface upwards, whilst the other last inked is turned down in readiness for the next impression. In conjunction with the slotted disc there is a stationary cap fitted outside the disc, which cap has an inclined surface made therein, over which the pin slides in descending, but on arriving at the bottom of its course it drops into a curved an incline slot, which guides it into a semicircular course, and causes it to carry half round with it the disc and die. Thus at each depression of the handle the upper surface of the die is inked, and at each elevation or release thereof that surface is turned under, and a fresh one brought under the inking pad. *Patent completed.*

3447. D. G. HOPE. *Improved machinery for obtaining and applying motive power.* Dated December 24, 1862.

In carrying out the object of this invention, the inventor mounts upon the face of a vertical fly-wheel three or more cylinders, in such a manner that they will balance each other. These cylinders he fits with loose plungers, and he brings the cylinders into communication (by means of the hollow shaft of the fly-wheel and a pipe) with the working cylinder of the engine. This cylinder he fits with a piston, connecting rod, and a crank shaft, in the same manner as an ordinary direct acting steam engine, with the exception that the front end of the cylinder is left open. The plunger cylinders on the fly-wheel are so arranged, that one or other shall be horizontal at the same moment that the piston of the working cylinder arrives at the end of the stroke. *Patent abandoned.*

3448. A. V. NEWTON. *An improved construction of skate.* (A communication.) Dated December 24, 1862.

This invention consists in so constructing the runner of the skate that it will form in its transverse section a section of a circle or a curve approximating thereto, and in providing the runner with longitudinal blades or projecting edges to catch into the ice and prevent lateral slipping. The invention further consists in applying to the skate or pawl a hold-fast arranged on a hinge joint, so as to offer no obstruction to the progresses of the skater, but to prevent a backward movement of the skate upon the ice. *Patent abandoned.*

3449. J. PLATT and W. RICHARDSON. *Improvements in machinery or apparatus for disintegrating or pulverizing artificial manures, chemical salts, and other substances.* Dated December 24, 1862.

Provisional protection has not been granted for this invention.

3450. C. J. DENTON. *An improvement in the process of revivifying animal charcoal.* Dated December 24, 1862.

The object of this invention is to effect the drying of animal charcoal in the filters in which it has been used, or in the cisterns in which it has previously been revivified, by what is known as the wet process. This the inventor proposes to effect by introducing into the filters or cisterns (as the case may be) suitable heating apparatus, such as steam or hot air pipes or flues, or by throwing blasts of hot or cold air into the filter or cistern, and causing it to

circulate therein, and thus carry off the moisture from the charcoal. *Patent abandoned.*

3451. R. Knox. *Improvements in the manufacture of metallic pens.* Dated December 24, 1862.

In carrying out this invention, the inventor proposes to form the pens either of steel, gold, silver, or other metal or alloys suitable for the purpose, and instead of pointing or nibbing one end of the pen only, as is ordinarily done, he proposes to form a nib at both ends. Thus each end of the pen may be made with fine points, or one point may be fine and the other coarse, or when desired one point may be extra coarse for engrossing. By this invention two pens may be formed of one piece of metal of about the same size as the ordinary pen. *Patent abandoned.*

3452. W. Clark. *Improvements in firearms.* (A communication.) Dated December 26, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3453. C. F. Varley. *Improvements in electric telegraphs.* Dated December 26, 1862.

The first part of this invention consists in employing for electric telegraphy the increment and decrement of electric currents, instead of, as has hitherto been the case, the flow of the current itself. The patentee carries this part of his invention into effect in various modes. Another part of the invention consists in the employment of what he terms a test circuit, formed by induction plates and resistance coils, so adjusted to each other as to produce an artificial line possessing the same amount of retardation as the cable itself. Another part of the invention consists in forming a contact piece of metal in the delicate spring contacts of telegraph instruments as described. *Patent completed.*

3454. E. T. Losesy. *Improvements in the construction of instruments for ascertaining the pressure and the moving force of the atmosphere.* Dated December 26, 1862.

This invention has for its object improvements in instruments for ascertaining the pressure of the atmosphere for increasing altitudes, and for ascertaining the direction and moving force of atmospheric and other currents. The said improvements relate, first, to the instruments for measuring the barometrical pressure of the atmosphere and other gaseous bodies or vapours, the object being thereby to obtain greater accuracy and longer ranges in a smaller and more portable instrument than the aneroid now used for that purpose. One method by which the patentee effects this improvement is by the introduction of a micrometer screw to measure the rise and fall of the vacuum box, in place of the ordinary aneroid mechanism of levers and chains. This micrometer screw is placed immediately over a steel stud, which is attached to the centre of the vaccum box, and projects above it; between this stud and the endof the micrometer screw a pivoted drop piece is placed, and which falls the instant the screw is unturned sufficiently to move the bearing points of the screw stud and drop piece out of contact with each other. By this improvement the amount of atmospheric pressure upon the vacuum box is accurately determined by the rotary motion of the screw, and indicated by a hand in connection therewith travelling round a graduated dial. Secondly, to instruments for measuring the force of horizontal vertical or oblique motions of air or other gaseous bodies from gentle currents to strong gales. One form of this improvement consists of a disc fixed on the end of a lever moving on a pivoted axis, and having a weight on the opposite side to counterpoise the disc and lever. A spiral spring is coiled concentrically with the axis, and attached to it at one end, the other end of the spring being secured to a dial, which in use is turned round to wind up the spring until its strength balances the force of the wind impinging on the disc, and thus enable its force to be read off on the dial. A second scale is placed at the end of the disc for measuring very gentle currents of air. *Patent completed.*

3455. J. Swainson. *Improvements in the manufacture of pill boxes and similar boxes from solid wood, and in the machinery to be employed in the said manufacture.* Dated December 26, 1862.

This invention consists in improvements in the manufacture of pill boxes and similar boxes from solid wood lengths, and in the machinery employed in the said manufacture, by which improvements great saving of wood and labour is effected. In making pill boxes and similar boxes, according to this invention, the patentee cuts the wood into short lengths, the said lengths being somewhat greater than the length of the boxes to be made, and he afterwards turns the exterior of the said lengths to the size required by means of a turning machine commonly called a thread bobbin machine, the said machine also fashioning one end of the wood length for the reception of the box-lid. He next places the said turned lengths in the holder of the machine hereinafter described, and by means of the said machine he bores or cuts out the inside of the wood lengths to the required depth. Pill boxes, or similar boxes, are thus manufactured, and are ready for the reception of the lids, the said lids being made by turning the exterior and boring out the interior of the short wood lengths as described with respect to boxes. *Patent completed.*

3456. W. H. Samson. *Improvements in certain machinery for cultivating land by steam power.* Dated December 27, 1862.

This invention consists -1, in constructing the apparatus used for ploughing as follows:—The plough-frame carries three ploughs, side by side, but a little in advance of each other; these ploughs can be turned so as to be a right or left-handed plough, similar to the Kentish plough; also, the position of the plough cad be changed—for instance, the first plough in advance can be drawn behind, the hindermost plough drawn to the front, the centre one keeping its position. 2, Two traction engines are used when ploughing, one at each side of the field, and opposite to each other, and attached to each engine is an inclined plane upon which the plough mounts as it arrives at either side, and thus withdraws itself from the soil. When entirely clear from the soil, the engine is moved forwards, the width of the plough carrying with it the inclined frame and ploughs; the ploughs are then turned round on the inclined planes, either by means of a turntable constructed thereon, or it is first lifted by a small crane and turned by hand. The position of the mould boards is then changed from right to left, or *vice versa*, as the case may be, and the first plough pushed backwards and the last one forwards, the middle one retaining its position, as described. The plough is then ready to recross the field, when the same operation is repeated. 3, In order to economize steam power as much as possible, the inventor couples the two engines together by means of a chain or rope, which passes round a pulley fixed to, and driven by, the engine from one to the other across the field, so that, when one engine is not drawing the plough, it may, through the means of the chain, assist the other. *Patent abandoned.*

3457. M. F. A. Courtois. *Improvements in wax and other candles and torches.* Dated December 27, 1862.

This invention consists in providing wax, stearine, spermaceti, tallow, or other candles, with a tubular wick or wicks, instead of with the solid wick hitherto made use of in such luminaries, for the purpose of procuring a suitable admission of air to the interior of the flame, and thus insure a better combustion. *Patent abandoned.*

3458. J. and S. Freemantle. *Improvements in apparatus for propelling vessels.* Dated December 27, 1862.

In carrying this invention into effect, the inventor proposes to construct a paddle attached to two arms, the ends of which arms are connected with moveable horizontal beams; the arms and paddles are actuated by means of a crank connected to the engine shaft, and situated on the exterior of the vessel within the paddle-box, a similar paddle with arms, beams, and crank being arranged on the opposite side of the vessel. The revolution of the crank will carry the paddles downwards and backwards in a descending and ascending curve, and will cause them, on leaving the water, to be extended to their foremost position on a level above the water, thereby avoiding contact with the surface of the water. *Patent abandoned.*

3459. J. Petrie. *Improvements in slide valves for steam engines.* Dated December 27, 1862.

The patentee claims—1, opening a portion of the back surfaces of slide valves to the atmosphere, or placing them in communication with the condenser; 2, forming slide valves as cylinders, or portions of cylinders, and imparting an axial motion thereto. *Patent completed.*

3460. M. Ker. *An improvement in wardrobes or other pieces of furniture or fittings, with glass silvered doors or panels used for toilet purposes.* Dated December 29, 1862.

This invention consists in the addition of a looking-glass to a wardrobe or other piece of furniture or fitting, having a glass silvered door or panel, in such manner as that it can be drawn out and adjusted so as to reflect in the glass door or panel the back of any person looking in it. This is effected by cutting the frieze of the cornice over the door or panel, and inserting sliding frames or other extending arrangements with a glass frame hung to them on centres. These frames or extending arrangements when closed will be entirely concealed behind the frieze, and when drawn out will extend the requisite distance behind the observer with the glass frame at the end of them, which can then be adjusted to the proper angle to cast the reflection of the observer into the glass door or panel when he is standing between it and the moveable glass frame. Cords and pulleys can also be applied to the extending apparatus, by means of which it can be drawn out and closed without being touched itself by the hand. The cord can be extended to any convenient part of the wardrobe or fitting, from which the apparatus may then be drawn out or closed. *Patent completed.*

3461. J. G. Taylor. *Improvements in dress fastenings, and in the ornamenting thereof.* Dated December 29, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3462. J. H. Riddell. *Improvements in cast metal or other pipes or tubes for conveying gases, fluids, or vapours, and in the mode of connecting such pipes or tubes.* Dated December 29, 1862.

This invention consists in forming a groove or recess in the face of the flanges the sectional form of which groove may be either the segment of a circle or any other convenient shape, and by preference the patentee forms this groove or recess in the face of the flange in the space between the internal orifice or bore of the pipe, and the holes cast and made in the flange through which the bolts or screws pass are used in connecting the different lengths or pieces of pipe together. These grooves or recesses being formed upon the face of each flange, must be arranged to meet with each other when brought together, forming a grooved channel round the face of each flange; and in connecting these improved pipes together, he places a ring of india rubber, hemp, or other suitable and elastic material in this groove, and draws the flanges together by bolts and nuts or screws, thereby compressing the elastic ring or packing, and forming a joint impervious to gas, water, or steam. *Patent completed.*

3463. J. H. Riddell. *Improvements in stoves.* Dated December 29, 1862.

This invention relates to improvements in stoves usually called hot-air or slow combustion stoves, and consists in an arrangement by which the heated or radiating surfaces of such stoves are so increased as to cause a large volume of air to be rapidly heated to a comparatively low temperature, instead of, as in former arrangements, heating a small volume of air to a high temperature, and which heated air can only be used after being mixed with a large volume of cold air. The patentee carries his invention into effect by forming a fire-box of cast iron or other material, which may be lined with fire-bricks, and which fire-box is connected with one or more chambers, through which the heated products of combustion pass on their way to the chimney or vent, such chambers being fitted with metal or other tubes either in a vertical or sloping position, through which tubes a current of air is constantly and rapidly flowing, and which air becomes heated in its passage, and prepared for warming and ventil[illegible]arches, or large halls or buildings. *Patent compl[illegible]*

3464. A. W. Sleigh. *Rendering or making ships and vessels and floating and shore batteries, or ambulant or stationary defences impenetrable to shot and shell and other missiles and projectiles and war rams.* Dated December 29, 1862.

This invention consists in the employment and use of elasticity and reaction obtained by the mode of arranging, placing in a certain direction, and fixing the hereinafter mentioned materials in the following manner:—The improved method is to construct elastic or reactionary metal plates or timber slabs of any required thickness or extent; this is done by placing between each of those plates or slabs (of equal size, but of much less thickness) a metal plate or timber slab, or several slabs or plates thickly and closely studded with tufts of thin fine fibre of vegetable or metallic or animal production, such as fine springing metal wires, bristles, or whalebone, or a fibre called drafts; those materials may be used singly or combined. *Patent abandoned.*

3465. F. Tolhausen. *The use of petroleum or coal oil as fuel, and also for the machinery and apparatus to be employed for this purpose.* Dated December 29, 1862.

This invention relates to the use of petroleum or coal oil as fuel, more especially for generating steam for operating machinery; also to tanks for containing, and a furnace for burning, the oil; and to apparatus or machinery for conveying the same to the furnaces as rapidly as may be desired. The furnace—which may be of any suitable size and shape, is constructed of ordinary materials. Instead of a grate or bars now used, the bed of the furnace is constructed solid, to prevent the escape of the fluid. This bed may be made either smooth or corrugated. The draught is obtained through a grating in the side or end of the furnace, which admits the air, but confines the flame, and an additional supply of air comes to the flames through pipes terminating within the walls of the furnace. The oil enters the furnace at the bottom, and is at first ignited by surrounding the mouth of the pipe through which it passes with a small quantity of burning coals. A cap may be placed over the furnace for protection, in case the flame should escape through the gratings. Tanks for holding the oil are provided with pipes, which permit the escape of explosive gases, and renders the use of this oil perfectly safe. These tanks are connected with each other, and with a distributing reservoir by pipes of suitable size. A steam or hand pump may be employed to draw the oil from the tanks to a distributing reservoir. From this reservoir, which is situated in a higher plane than the bottom of the furnace, the oil passes into the furnace, the flow being regulated as may be desired by a stop-cock, which is governed by the pressure of steam or by hand. A waste-pipe carries back any surplus that may accumulate in the distributing reservoir to the tanks. *Patent completed.*

3466. G. Haseltine. *Improvements in cartridges, and in the mode of charging small arms and ordnance.* (A communication.) Dated December 29, 1862.

This invention consists in separating the powder or other explosive substance of a cartridge or charge into two or more parts, by means of a disc or discs made of metal, hard wood, or other suitable material. The discs are made to fit closely, thereby forming a complete separation of the explosive material, with the exception of a central perforation through which the fire is communicated from one part to another of the cartridge or charge. When these discs are employed, the separated portions of the charge successively explode, and a perfect ignition of the powder is secured. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated March 27, 1863.

807. J. King, Chadshunt Farm, near Kineton, and T. H. Marshall, Combrooke, Warwick. Improvements in machinery and apparatus for preparing land for seed, and for harrowing land.

Dated June 2, 1863.

1375. G. H. Cottam, St. Pancras Iron Works, Old St. Pancras-road. Improvements in bricks suitable for being used for paving stables and other places.

Dated June 17, 1863.

1519. F. de Wylde, Great College-street, Camden Town. An improved means for the protection and preservation of lead surfaces exposed to the action of water, and for the protection of such surfaces from decomposition by atmospheric action. (A communication.)

1522. A. Samuelson, 28, Cornhill, engineer and steam ship builder. Improvements in apparatus for evaporating liquids.

Dated June 19, 1863.

1540. W. Hicklin, Balls Pond. Improvements in metal screens and sieves for screening and sifting, applicable also to other openwork articles.

Dated June 20, 1863.

1559. W. Clark, 53, Chancery-lane, engineer. Improvements in the treatment of broom for the manufacture of paper pulp. (A communication.)

Dated June 23, 1863.

1578. W. W. Sleigh, London, doctor of medicine. A new method for obtaining motive power.

Dated June 24, 1863.

1592. E. Myers, 2, Millbank-row, civil engineer, and W. R. Williams, meter maker, 35, Lamb's Conduit-street. Improvements in wet gas meters.

Dated June 25, 1863.

1598. C. A. Count de Goddes de Liancourt, 19, Holly-street, Dalston. Improvements in apparatus for the preservation of life from drowning.

Dated July 3, 1863.

1654. W. E. Newton, 66, Chancery-lane, civil engineer, Improvements in the treatment and preservation of of all kinds. (A communication.)

1656. C. Baulch, Bristol, boot manufacturer. Improvements in the manufacture of boots and shoes.

1658. H. Thomas, Birmingham, manufacturer. An improvement or improvements in candle-sticks.

1660. E. Lelios, Threadneedle-street. Improvements in the means of and apparatus for churning.

Dated July 4, 1863.

1666. H. A. Bonneville, 24, Rue du Mount Thabor, Paris. Improvements in steam engines. (A communication.)

1670. J. Oxley, Frome, brickmaker and engineer. Improvements in filtering apparatus.

Dated July 6, 1863.

1672. A. Gower and B. S. Gower, Market Drayton, agricultural engineers. An improved sowing and harrowing machine.

1676. J. McG. Croft, 8, Abbey-road, St. John's Wood, doctor of medicine. Improvements in propellers for propelling vessels.

1680. G. C. Collyer, 152, St. George's-street East, tobacconist. Improvements in the treatment of cut tobacco for its better preservation.

Dated July 7, 1863.

1684. E. Edwards, Birmingham, manufacturer. Improvements in instruments or apparatus to be used in the manufacture of glass finger plates and other articles made of glass, and in kilns for annealing articles made of glass.

1686. J. Orr, Kidderminster, manager. Improvements in weaving piled and other fabrics, and in the machinery or apparatus connected therewith.

1688. W. E. Gedge, 11, Wellington-street, Strand. Improved apparatus for milking. (A communication.)

Dated July 8, 1863.

1692. G. Haseltine, 12, Southampton-buildings, Chancery-lane, civil engineer. Improvements in brick machines. (A communication.)

1694. F. Ely, Totton, Southampton. An improved composition applicable to corn plasters.

1700. R. and L. A. Tallerman, 131, Bishopsgate-street Without. A new method of waterproofing and ventilating boots, shoes, and slippers, for preventing wet and damp feet.

1704. J. Thomas, Battersea, ironfounder. Improvements in treating ores and earths containing iron in order to obtain the metal therefrom.

Dated July 9, 1863.

1708. E. Phillipson and W. Bond, Accrington, overlookers of power looms. Improvements in temples for looms.

1710. P. G. B. Westmacott, Newcastle-upon-Tyne, civil engineer. Improvements in cranes and in dock-gate and other crabs.

1712. P. G. B. Westmacott, Newcastle-upon-Tyne, civil engineer. Improvements in hydraulic engines.

1714. R. Agate, Hornsey, plumber and builder. Improvements in the construction of skylights and rooflights for railway stations, conservatories, and other similar structures.

1716. W. Tent, Birchin-lane, glover and hosier. Improvements in pins or hooks for suspending fabrics, dresses, or parts of dresses, curtains, and other articles of upholstery or apparel.

1718. W. Tasker, Waterloo Iron Works, near Andover, agricultural engineer. Improvements in thrashing machines.

Dated July 10, 1863.

1720. A. R. Johnston, Grove, Yoxford, Suffolk, gentleman. An improved portable fence for sheep and cattle pens or for other enclosures.

1722. J. J. Shedlock, 12, Abingdon-street, Westminster, engineer. Improvements in the construction of soil pits, and in the mode of emptying the same. (A communication.)

1724. W. Clarke, Forest-road, Nottingham, lace manufacturer. Improvements in the manufacture of ornamental lace.

1726. R. Hornsby, jun., J. Bonnall, and W. Astbury, Spitalgate Iron Works, Grantham. Improvements in traction engines, and in apparatus for ploughing and tilling lands by steam and other power, part of which improvements is also applicable to driving or giving motion to machinery.

1728. W. Henderson, Kensington, chemist. Improvements in treating ores and other substances containing iron, in the manufacture of iron, steel, and alloys of iron, and of a purifying and deoxidizing agent therefrom, also in the constructinn of retorts or kilns for treating the said ores and substances.

1730. J. Campbell, Silvertown, Essex, contractor. Improvements in the permanent way of railways, and in supporting the rails thereof.

Dated July 11, 1863.

1734. M. W. Ruthven, 72, Oxford-terrace, Hyde-park, engineer. Improvements in rudders or apparatus for steering vessels.

1736. J. Orr, J. Brinton, and J. Lewis, Kidderminster, carpet manufacturers. Improvements in weaving "chenille" and in the machinery or apparatus connected therewith.

1738. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in cartridges for breech-loading arms. (A communication.)

Dated July 13, 1863.

1740. J. Mortimer, 47, Gresham-street, architect and builder. Improvements in the construction and arrangements of dwelling-houses in combination with the means employed for ventilating the same.

1742. H. Coulter, Liverpool, lamp manufacturer. Improvements in the burners of hydro-carbon and other fluid burning lamps.

1746. R. S. Walker, High-street, Wapping, ship surveyor. Improvements in sheathing or coating iron ships.

Dated July 14, 1863.

-- C. Opperman, King's-road, Peckham, chronometer [illegible]. Improvements in means or apparatus to facilitate the connecting and disconnecting horses and other animals with carriages.

1753. J., T., and F. R. Holmes, Norwich, agricultural engineers. Improvements in thrashing and dressing machines.

1760. J. Davison, Southwick, near Sunderland. Improvements in furnaces for boilers, smelting, and other useful purposes.

1762. W. Wood, Monkhill, near Pontefract. Improvements in "warping" or covering land, bog, or peat, with earth or soil.

1764. W. Roberts, Lylands Twyford, near Winchester, farmer. Improvements in ploughs.

1766. J. Slater, Derby-villas, Park-row, Plaistow, engineer. Improved machinery for compressing bricks, tiles, and other plastic materials.

Dated July 15, 1863.

1768. T. Wimpenny, Holmsfirth, York, manufacturer. Certain improvements in machinery or apparatus for roving and spinning wool, cotton, and other fibrous substances.

1770. W. H. Cheetham, Ashton-under-Lyne, mechanical draughtsman. Improvements in obtaining hydraulic motive power.

1772. P. A. J. Dujardin, 29, Boulevart St. Martin, Paris, physician. Improvements in electric telegraphs.

1774. R. A. Brooman, 166, Fleet-street, patent agent. Improved means of, and apparatus for, reducing charcoal and other friable substances to fine or impalpable powder, particularly applicable to the manufacture of a substitute for lamp black. (A communication.)

Dated July 16, 1863.

1782. H. Elliott, Birmingham, gunmaker. Improvements in breech-loading firearms.

1784. L. R. Bodmer, 2, Thavies-inn, Holborn. The manufacture of a new product from peat and peat tar. (A communication.)

1788. A. Montleart, Mildmay-park, widow, and W. Tent, of Birchin-lane, glover and hosier. An improved mode of attaching hooks to furniture or fabrics for suspending dresses or parts of dresses, fabrics, curtains, and other articles of upholstery or apparatus.

1790. O. Wakefield, 10, Union-place, Lambeth-road, Lambeth. Improvements in cocks or taps.

1792. E. Maw, Leamington. Improvements in the manufacture of pillars, posts, columns, mouldings, and buildings, when corrugated metal is employed, and in machinery used in corrugating, moulding, and shaping metal for such purposes.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, July 28, 1863.

702. F. Hoyos. Stove or firegrate.

704. W. Vernon. Communicating signals or intelligence to or from railway trains.

709. W. G. Eavestaff. Pianofortes.

712. W. H. Atkinson. Studs or fastenings.

713. W. E. Gedge. Framing pictures, looking-glasses, and other objects. (A communication.)

721. W. Donbavand and D. Crichton. Looms.

722. J. Roberts and R. Naylor. Organs, harmoniums, and pianofortes.

728. E. Legris. Thrashing out the seed of flax.

729. T. Oldknow. Construction of jacquards.

731. W. Lorberg. Treatment of rags and obtaining valuable chemical products from the animal fibre therein.

732. A. Morel. Generating carbonic acid.

751. J. Brigham and W. Bickerton. Reaping or mowing machines.

757. E. Hartley, J. Clegg, T. and J. Mellodew. Looms.

758. J. M. Hetherington. Combing cotton and other fibrous materials.

768. H. Cook. Transmitting electric currents and signals for telegraphic purposes. (Partly a communication.)

773. A., J., and J. Topham. Manufacture of ornamental twist lace.

807. J. King and T. H. Marshall. Preparing land for seed.

811. J. Leeming and R. S. Markindale. Carding engines.

819. H. Hughes. Shaping metal and plastic substances.

840. W. West. Working railway signals.

847. E. F. Clarke. Fastening rails for railways.

849. J. Cassell. Distillation of petroleum and other heavy oils.

871. E. T. Hughes. Manufacturing the ornamental tips of parasols, umbrellas, and similar articles. (A communication.)

1035. L. A. J. Bruet. Registering, indicating, and verifying the time and distance passed over by vehicles.

1040. A. Legras. Making ices.

1357. E. T. Hughes. Transmission of motive power. (A communication.)

1375. G. H. Cottam. Paving stables and other places.

1376. D. Wilson and E. A. Cowper. Presses.

1478. G. Davies. Oiling journals or axles. (A communication.)

1648. E. Lloyd. Waterproofing, softening, and preserving all kinds of leather and articles made therefrom.

1690. G. P. Reed. Watches or timekeepers.

1724. W. Clarke. Manufacture of ornamental lace.

1772. P. A. J. Dujardin. Electric telegraphs.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, AUGUST 7, 1863.

IMPROVED ORDNANCE.

Whichever system of ordnance may be ultimately adopted for fighting the battles of the country—whether the chosen plan be Armstrong's, Lancaster's, Whitworth's, Blakeley's, or Thomas's; whether it be a combination of the best points of each system; or whether (as is most likely) a special build of gun be ultimately used for each particular service—there has certainly been no lack of discussion as to the relative merits of the different guns and their several inventors. Ever since the quondam Newcastle solicitor prevailed over the ordinary coyness of Government officialdom, and received a title, a fortune, and a reputation as a reward for his *ingenuity;* like the "Champion of England," Sir William Armstrong has had to meet the onslaughts of all comers; while the merits of his guns and the originalities of their details have been questioned on all sides by his rival competitors in ordnance improvements. With an appropriateness to the subject delightful to contemplate, a merciless cannonade on paper has raged at intervals for several years, to the bewilderment of the uninitiated and the amusement of a few. Fully prepared, by the law-training of his youth, Sir William Armstrong has always vigorously backed up by his pen the productions of his workshop; Mr. Whitworth has retained a distinguished legal gentleman for the defence of *his* system of artillery; while the gallant Captain Blakeley has conducted his own defence in person. A mere recapitulation of this paper warfare would take up many pages; it may be sufficient to state that no combatant has come off completely victorious. The only feasible plan of ending the contest would appear to be an actual triangular duel, similar to the species of combat advocated by that friend of our youth, Mr. Midshipman Easy; and to the gun and inventor coming out of the ordeal with the least damage, should be adjudged the palm of merit. The ordnance gentlemen, however, have not had all the campaign to themselves; and amidst the roar of artillery, the sharp crack and whizzing bullets of a rifle have been occasionally heard. The instant that any marked feat had been accomplished by any one of the rival artillerists—such as that of the flat-pointed shell by Mr. Whitworth—a concise little note from the veteran Captain Norton would make its appearance in the public prints, suddenly laying the embargo of priority on the merit of all inventions whatsoever in projectile warfare, and a more special and determinate claim to the invention that might be in question.

The inquiries as to relative priority of invention are evidently of no importance to the nation, and rival inventors may well be left to fight out such questions amongst themselves; the relative merits of gun construction, however, are questions of national importance, which cannot be put off to the decision of the hour of trial on a field of battle. Urged by the representations of the press in general, and of this journal in particular, the Government appointed a Select Committee last year to inquire into "the expenditure incurred since the beginning of 1858 on various improved natures of ordnance," and the result is a report, now lying before us—in substance a mere apology of the Government for its shortcomings with regard to the Armstrong gun.

As almost all the outlay incurred during the last five years was on Armstrong guns, the report sets out with a history of the adoption by the Government of this system of ordnance. It thus appears that the then Mr. Armstrong first made half-a-dozen of his guns in 1854 for the Government, and that one of these guns was favourably reported on after an examination by the Ordnance Select Committee. This same gun was re-bored up to a 5-pounder, and in December, 1856, its practice at 1,500 and 2,000 yards was said to be excellent. In the beginning of the year 1858 another gun was tried with success in competition with a service 32-pounder, and in the presence of the Ordnance Select Committee. Two 18-pounder guns were then ordered by Government, and their performances being favourably reported on by Colonel Lefroy, General Peel appointed a Special Committee to fix upon the best rifled gun for field service. It is reported (with what truth we know not) that the previous *Select* Committee—under the Presidency of General Kater, well known for his scientific attainments—found themselves unable to give a favourable report on the Armstrong gun. This latter Committee determined to examine no other guns but those of Armstrong and Whitworth; and as Mr. Whitworth had then no guns of his own construction, nor any particular system of gun, and as he "had only rifled Government blocks of brass and cast-iron," the experiments were almost confined to Mr. Armstrong's system. The Committee thus consider that the adoption of the Armstrong gun by the then Secretary of State for War was fully justified.

A guarantee was then given to Sir W. Armstrong to enable him to expend £12,000 on plant and machinery. In 1859 he made over all his patents to the Government. In order to increase the number of guns to be delivered, the Elswick Company was formed in 1859; and the guarantee was progressively raised from the original amount to £50,000, £60,000, and lastly—by Lord Herbert in October, 1859—to £86,000. Sir W. Armstrong was appointed "Engineer of Rifled Ordnance" in February, 1859, and "Superintendent of the Royal Gun Factory" in November; and having resigned these two posts in February last, and the engagement with the Elswick Company being also terminated two months later, the £86,000 guarantee money have been handed over to the Company, for which only £19,000 has been returned to the Government in plant and stores. During this time, the sum of £1,471,753 1s. 3d. was being spent at Woolwich on Armstrong guns; and with the sums paid, and those still due to the Elswick Company, a grand total of more than two millions and a-half of pounds sterling have been expended on Armstrong ordnance.

The evidence adduced before the Committee is scarcely doubtful as to the results of this enormous expenditure, although the Duke of Cambridge and the Adjutant-General of Artillery are stated to be "perfectly satisfied with the Armstrong field-gun." Colonel Bingham qualified his opinion by the assertion that half the field-guns in the service are "patched up;" in answer to this, Mr. Anderson, of Woolwich, adduces an ingenious theory of progressive improvement in the manufacturing of Armstrong guns. The preponderance of opinion of witnesses is evidently against the Armstrong gun for field-service on account of its liability to damage through its complication; although, on the other hand, it appears to the Committee itself that "the Armstrong field-gun is the best known for field-service." For efficiency against iron plates the old 68-pounder is, on all hands, acknowledged to be immeasurably superior, as is well pointed out in the letter of Admiral Halsted in our present number. Substantially, what is called Armstrong's system of ordnance evidently stands or falls with the contrivances for breech-loading; and the "shunt system," by which Sir W. Armstrong "attempted to have muzzle-loading guns rifled—without mechanically fitting projectiles—is still an experiment."

Each marked stage towards the culmination of this job—the most gigantic specimen of modern times—is rounded off with some impotent excuse. Where was the Lancaster gun when in 1858 only Armstrong's was tried? This report states that the then Committee refused to try any other guns but those of Whitworth and Armstrong, "because it was not expedient to incur the expense;" and in the very next paragraph it is stated that Whitworth had no system at all. Two millions and a half of pounds sterling have thus been spent by the penny wisdom that refused to expend a few hundred more pounds in experiments. Lord Panmure seems to have had some qualms as to the endurance under actual service of Armstrong's complicated breech-loader, and he advised that the guns "should be handed over to the artillery to knock about, and be reported on as to their endurance of work." Lord Derby, however, took the most common sense view of the question, and in a letter to General Peel, in December, 1858, he strongly deprecates "the expediency (in the then infancy of the invention) of pressing for the immediate supply of a large number of guns." At the conclusion of the report, the Committee—although confessedly believing that the Armstrong gun is still the best—advise that all the different systems now before the public may be experimented upon; that scientific men be freely admitted to the trials; and that all the different guns to be tried be manufactured with an equal amount of good workmanship.

In conclusion, we cannot help remarking, that we ourselves have previously anticipated almost all the opinions of the report. In our volume for 1860, pp. 317, 360, 381, and 413, we pointed out the enormous cost of the Armstrong gun; and in other places we have shown up its mechanical structure. We are thus justified in looking upon this report as a triumphant answer to the stricture made by Mr. Baring, in the House of Commons, on our statements in our number for the 1st of March, 1861—for in that article is contained the main substance of the report we have just examined.

THE SUEZ CANAL.

Projects never present themselves in so dangerous a light as when they appear extremely easy of execution. The diplomatist and the financier, the general commanding armies, and the engineer weilding the powers conferred on him by money and science, can equally bear testimony to the truth of our proposition. When an individual or a company, a government or a nation, ardently desire the accomplishment of a scheme, or the gratification of a desire, calm reflection is seldom employed in investigating the importance of the difficulties to be overcome. Obstacles shrink within their due proportions, and are underrated and combated, in a spirit which fails to provide for contingencies, listens with difficulty to the warnings of experience, or the reasonings of science, and but too frequently plunges into a strife from which it comes forth perhaps vic-

torious, after an expenditure of energy, money, labour, and intellect, which renders the dear-bought victory worthless to the victorious. The strife might never have been entered on, possibly, had not the enemy seemed so weak, the obstacles so trifling.

The scheme for uniting the Mediterranean with the Red Sea, is just such a project, which its proposers undertake to conduct to a successful termination, in just such a spirit. The apparent ease of its execution is the very point which renders its accomplishment most unlikely. It seems unreasonable that the people of Europe, with all the vast resources at their command, should permit a wretched barrier of one hundred miles or so of flat sandy desert, to enforce a detour of some thousands of miles on ships proceeding to the East Indies or Polynesia; and the practicability of removing such a hindrance to commerce, appears still more evident when we remember that the Isthmus of Suez is already a valley under water for more than half the distance to be traversed by a ship canal. Lake Menzaleh extends inland, from Port Said on the Mediterranean, more than 30 miles; Lake Ballah, its continuation, nearly 10 more; while Lake Timsah and the Bitter Lakes increase the distance already under water to 70 miles, or thereabouts, leaving apparently about 30 for actual excavation. Such is the state of the question as far as we can gather information from the map; and 30 miles of excavation is such a trifling task, and the advantages to be gained by its execution are so manifest, that we feel no surprise that the work has been entered on with vigour and energy. M. Lesseps is by no means the first proposer of a scheme which promises to open a gate of communication between the West and the East.

The results of an experience extending over many months, and of investigations carried out with a moderate degree of care, have dispelled much of the illusion; and we find that the execution of this work is encumbered with difficulties of the gravest character on every side. Thus the very lakes which were once considered as being so much of the work already accomplished, are in reality amongst the most serious obstacles to be encountered. Too shallow to be available for navigation, they are deep enough to preclude all the ordinary operations of excavating, imperatively dictating a recourse to the tedious and expensive process of dredging, in order to provide a sufficient depth of water to render the proposed canal available for ships of even moderate tonnage. The sinking of a canal for a distance of nearly 20 miles under water, through Lake Menzaleh—even if dredging is not found necessary through the Bitter Lakes—is no slight engineering achievement, however lightly its proposers may be disposed to regard it. This work alone, cannot fail to demand the expenditure of a sum of money which scarcely admits of an approach to accurate estimation when we consider the treacherous nature of the materials to be excavated. The bottom of the lake is generally sand; and the difficulty of forming anything like a well-defined channel, without the removal of ten times the proper quantity of material, requires none of the colouring of imagination to show its importance. The mere opening of such a subaqueous canal, is not perhaps the worst. It is more than probable that it will be necessary to embank it, in order that ships in passing through, may not fall foul of margins rendered invisible by the depth of water above them. When we reflect that this embankment must be formed of sand or loose material, deposited in great part under water, in just the semi-fluid state in which it leaves the bottom of the excavation in the buckets of the dredger, we think no engineer will be rash enough to determine positively the slope at which it will stand, or the quantity to be dredged.

Mr. Hawkshaw's able report to the Egyptian Government on the construction of this canal lies before us. The eminence of Mr. Hawkshaw's professional reputation, entitles his opinions to deep consideration; a consideration, indeed, which might probably set the matter at rest under other circumstances. In the present case, however, singularly enough, such different sentiments are entertained by men of the highest standing as engineers; that the expressed opinion of any one individual, no matter how able he may be, bears too little weight to be of any very great practical value. It is just a case where the multitude of councillors is not wisdom; and agreeing with Mr. Hawkshaw's views in the main, as we do, we still feel inclined to believe that he has underrated every difficulty to be encountered, as well as the probable expense at which they can be overcome. It is true that his report merely glances at the financial department of the undertaking; still, he tacitly admits the truth or probable accuracy of certain estimates which have been laid before him, and which we consider far too low. On this subject, however, it is impossible to speak positively, without folly. It is one of those questions which only future events can decide. The two French engineers, M. Mongel Bey and M. Linant Bey, who prepared the estimates for the International Commissioners, have, it is true, resided a long time in Egypt, but they have had no experience whatever as regards the deep-dredging of the canal at its entrance; just the situation where unforseen events may occasion an enormous outlay.

We do not wish our readers to imagine that we disbelieve in the feasibility of the work. On the contrary, there is not, so far, any evidence before us of the existence of an obstacle which can prevent the canal being finished in a satisfactory manner. We do, however, more than doubt the possibility of bringing the scheme to its proper termination, without an expenditure of money on which no traffic which the canal is likely to enjoy can pay a fair dividend. Fifty years ago, when a great work was proposed, the nation asked, "Is it practicable?" Half a century's experience in engineering works, and the commercial transactions on which they are based, has altered the question to "Will it pay?" and although we do not doubt for a moment that the Suez canal may prove a magnificent triumph of civil engineering, we have little reason to conclude that it will not be a commercial failure as well.

Quitting for the present the monetary consideration of the question, let us examine the works yet to be executed. Not the least important of these is the completion of the canal which is intended to supply the workmen engaged in the desert, with fresh water brought from the Nile near Cairo. The greatest difficulty in carrying on engineering operations in the East is frequently found in the want of water; and the difficulty certainly attains a maximum when many thousands are employed in the midst of an arid desert, under a tropical sun. M. Lesseps' men have been hitherto almost without water, save that brought for their use on the backs of camels. The canal, however, lately opened between Ras-el-Wadé and Timsah, provides a supply for a short time until the dry weather sets in, ere which the directors of the enterprise hope to have it completed from Timsah to Suez, and from Ras-el-Wadé to Cairo. Suez is at present wholly without fresh water, except that brought by railway from Cairo. The total expense of this preliminary work is estimated at £360,000. The work to be executed on the main canal is concisely put before us by Mr. Hawkshaw:—

Beginning at Suez, a channel will be dredged into sufficiently deep water. The mouth of this channel is to terminate to the southward of the entrance to the basin and graving dock, now constructing for the railway and steam packet traffic. The portion to be dredged will average 16½ ft. deep. Between the upper end of this dredged channel and the Bitter Lakes is a distance of 12½ miles, and the canal between these points will be wholly in excavation, varying from 29½ ft. to 55¾ ft. in depth.

The canal will pass through the Bitter Lakes for about 23¾ miles. Between the Bitter Lakes and Lake Timsah the canal will be in excavation for a distance of 8 miles, the depth of the cutting in this length varying from 29½ ft. to 62 ft. It will then pass through Lake Timsah for a distance of 2¾ miles, the excavation of this part averaging about 26 ft deep. At El Guisr, which lies between Lake Timsah and Lake Ballah, a distance of 11½ miles, the canal encounters the highest ground. The depth of the excavation between these two lakes will vary from 29½ ft. to 85 ft. From the south end of Lake Ballah to Lake Menzaleh is a distance 11 miles, and the depth of excavation between these points will average 29½ ft. The canal then passes through Lake Menzaleh, and with small exceptions the ground throughout this lake is below the level of the sea. The distance between the south end of Lake Menzaleh and Port Said is 20 miles, and the depth of excavation will average 24¾ ft. The works at Port Said consist of a basin 875 yards square, and of an eastern and a western stone jetty extending into the sea. The eastern jetty will be 3,609 yds. long from the coast line, and the western jetty 2,515 yds. long, and the distance between the two is to be 437 yds. The channel between these jetties is to be dredged to a depth averaging 11½ ft. below the present surface. The canal between Suez and the Bitter Lakes was originally intended to be 328 ft. wide, and 262½ ft. wide between these lakes and the Mediterranean. The width between the Bitter Lakes and the Mediterranean is now intended to be 190 ft. The reduced width between the Bitter Lakes and Suez is not yet determined upon, but it will probably be 262½ ft. The length of the canal, from sea to sea, will be 90 miles.

Now, it certainly seems at first sight incredible that works such as these, dealing with no materials more obdurate than sand or clay, should require the outlay of nearly £8,000,000. Yet the mere fact that such is the estimate, places in the strongest possible light the immense difficulties to be encountered from the presence of water, the system of labour, and the want, in a secondary degree, of proper facilities for the supply of necessaries. Mr. Hawkshaw wisely admits that even £10,000,000 may be required; and it would be folly to assert that even this sum is sufficient. The dredging of entrances through treacherous sands, and shoals which constantly shift, is in itself a work of the greatest magnitude and uncertainty. Even after the expenditure of this money, and the completion of a navigable channel, the work does not cease. The maintenance of the canal cannot fail to demand the yearly expenditure of a large sum. Inland, there will be little difficulty in keeping the bed clear of sand or deposit, and we are not disposed to agree with Stephenson that the canal will become a stagnant lake. The evaporation from the large surface exposed by the

inland waters; the slight changes of level produced by the tides; will, in combination with moderate dredging, suffice to prevent any inconvenience of this kind. It is on the sea-shore, from sand drifts brought down by the Nile, that the real difficulty is to be expected by the consequent silting up of the entrances. Mr. Hawkshaw seems to regard the danger as trifling; but even if the Nile never brought down a grain of sand, who can foretel the effect which might be produced by a gale in the Mediterranean, on a channel dredged in sand and imperfectly protected? Steam or other vessels, too, instead of stopping at Alexandria, will have to perform a rather dangerous voyage of more than 150 miles ere they can reach Port Said; a risk which will deter many from using the canal.

Commercially speaking, we cannot conceive how the canal can prove othewiser than a failure. In an engineering sense, there is nothing to prevent its success, provided funds are supplied; and of this there can be little doubt, should the French Government once identify itself with the scheme. Its magnitude and importance are well calculated to extend French honour and power in the East; but with such political questions we, as engineers, have nothing to do. In any case, the present system of forced labour, for the employment of which M. Lesseps has once more got the sanction of the Porte, cannot fail to prove to the last degree injurious to Egypt, and its effects will be felt for many years to come, without the prospect of a benefit, as far as the country is concerned, which could make the existence of the system excusable.

THE COINAGE OF 1862.

A return has just been published of the number of coins of all denominations issued from the Mint during the year 1862. Why that return makes its appearance at so late a period in the present year we know not. It is just possible, however, that *red tape* may have had some share in causing the delay. From this tardily printed official document, we gather that from the 1st of January, 1862, to the 31st of December, in the same year, there were coined at Tower-hill 7,886,413 sovereigns, the total weight of which was 2,012,562·126 ounces. No half-sovereigns were struck, and this therefore comprises the total gold coinage of 1862.

Crowns and half-crowns have long since ceased to be coined, and the next denomination of money referred to in the return is the florin. The number of florins pressed into existence during the period named was 594,000, representing a weight of 216,000 oz., and a value equal to £59,400. Of shillings the quantity struck amounted to 954,300, weighing 173,520 oz., and being worth £47,718 sterling. The number of sixpences produced in 1862 amounted in number to 990,000, in weight to 90,000 oz., and in value to £24,750. There appears to have been a comparatively much greater demand for threepenny pieces, for they equal in number 1,160,808, in weight 5,267·73 oz., and in value £14,510 2s. This list comprises the whole of the silver coinage proper of the year, for like crowns and half-crowns the groat appears to have become obsolete. In addition, however, there were struck for circulation in our West Indian Colonies, 319,774 three-halfpenny pieces of the same metal, weighing in all 726·71 oz., and equalling in value £1,998, 11s. 10d.; besides the annual batch of Maundy money, composed of fourpences, twopences, and pence—these latter numbered, in the aggregate, 16,830, weighing 516 oz., and being worth £141 18s.

Of bronze money, the statistics for the year 1862 are much heavier; but in this case the exertions of the Royal Mint have been supplemented to a very considerable extent by the celebrated engineering firm of James Watt and Co., Soho, near Birmingham, who contracted to supply no less than 1,720 tons of pence, half-pence, and farthings. We accordingly find that the number of new pence put into circulation was no less than 50,534,400, weighing 470 tons, and representing £210,560 in value. The half-pence coined amounted to 61,107,200 pieces, the weight of which was 341 tons, and its nominal value £127,306 13s. 4d. Of farthings, there were struck and issued 14,336,000, weighing 40 tons, and being nominally worth £14,933 6s. 8d.

We have deemed it proper to render an exact account of the moneys coined in 1862, because in the *Times* and other journals the coinage returns of the last ten years have been mingled in inextricable confusion, and are, therefore, of no value as regards any particular year. The general summary of the coinage of 1862 stands as follows:—

Gold coins struck.	Silver coins struck.	Bronze coins struck.
7,836,413.	4,035,412.	125,977,600.

The bronze coinage has been going on at a corresponding rate up to the present time, and nearly another hundred millions of pieces have consequently been put into circulation this year.

VENTILATION OF COLLIERIES.

It has long been admitted that theoretically machine ventilation is superior to furnace ventilation, inasmuch as there is something very anomalous in introducing an enormous furnace into a colliery, in which the greatest enemy to be contended with is an inflammable gas of the most destructive character, but in practice it has hitherto been found, that from the great difficulty in obtaining anything like the theoretical quantity of air by a mechanical contrivance, it is preferable to rely upon the furnace as the smaller of two evils. It is only within the last few months that the success achieved at the West Ardsley Colliery has afforded some tangible evidence that coal cutting by machinery can be satisfactorily and economically substituted for hand labour, and it is now stated that at the same colliery a system of mechanical ventilation is in operation which promises equally good results. The West Ardsley ventilator is the invention of Messrs. Ridley and Jones, and may be briefly described as a modification of some of the more approved forms of centrifugal pumps; such modifications, however, being of so important a nature that no difficulty is found in passing 100,000 cubic feet of air per minute with a comparatively small apparatus, propelled by no more than a 15-horse power steam-engine. The top of the upcast shaft is closed from the external air, and placed in direct communication with the centre of the apparatus itself, the opening between the shaft and apparatus being of the full size of the shaft itself, and so constructed as not to interfere with the passage of the air.

The apparatus consists of a series of spiral chambers, which rotate upon an axis carried in suitable bearings. The spiral chambers are thus produced:—The periphery of the apparatus is not cylindrical, but is formed with openings, by preference four, in planes radiating from the centre of the apparatus. The circumference of the apparatus is closed, except at these openings, by four curved plates, if there be four opening, or outlets, each plate springing from the inner end of one opening to the outer end of the next. The apparatus when in use is caused to rotate with considerable velocity in such a direction that a partial vacuum shall be produced in the spiral chambers, by which means the air is drawn from the upcast shaft into the apparatus, and escapes by the several outlets. It is found in practice that the apparatus works most efficiently in a vertical position, but it is obvious that it may also be placed horizontally by arranging the centre of the apparatus over the upcast shaft, and closing the opposite side; the position of the axle and bearings being necessarily suitably varied.

The dimensions of the apparatus, which must be published in order to enable an opinion of the efficiency of the machine to be formed, are:—Diameter from [illegible] point of two opposite chambers in feet; distance from centre of axis to inner end of chamber in feet; size of central openings to shaft, one on each side, in feet; width of periphery in feet; width of nearest axis in feet; total weight of apparatus in cwts.; and the number of revolutions per minute to produce a current of 100,000 cubic feet per minute. The extent of workings in the colliery at which the apparatus is applied must also be made known, and also the length of time that the apparatus has been in continued daily use, without requiring any repair or attention whatever.—*Mining Journal.*

TRIAL OF ROBERTS' STEAM FIRE-ENGINE "PRINCESS OF WALES."

On Friday evening, the 31st ult., a trial took place of this engine (which had previously been highly commended at the late Crystal Palace Trials) at Millwall, in the presence of one of the engineers of the East Indian Railway, Mr. Edinger, of the East London Waterworks, Lieutenant Becker (Hodges' Fire Brigade), Messrs. E. Field, C.E., F. Wise, C.E., D. Siebe, C.E., and a large party of scientific gentlemen.

The fire was laid in the ordinary manner without any turpentine, tallow, or naptha, and in 2m. 45s. from lighting the fire, everything being perfectly cold, the steam pressure was 5lb. on square inch; in 6m. 30s. = 10lb.; in 7m. 10s. = 15lb.; in 7m. 40s. = 20lb.; in 8m. 15s. = 25lb.; in 8m. 30s. = 30lb.; in 8m. 55s. = 35lb.; in 9m. 11s. = 40lb.; in 9m. 25s. = 45lb.; in 9m. 42s. = 50lb.; in 9m. 55s. = 55lb.; in 10m. 5s. = 60lb.; in 10m. 46s. = 65lb.; in 10m. 28s. = 70lb.: in 10m. 37s. = 75lb.; in 10m. 50s. = 80lb.; in 10m. 56s. = 85lb.; in 11m. = 90lb.; in 11m. 10s. = 95 lb.; in 11m. 15s. = 100lb.; in 11m. 22s. = 105lb.; in 11m. 27s. = 110lb.; in 11m. 35s. = 115lb.; in 11m. 40s. = 120lb., at which pressure the engine was set in motion, and drawn from the yard to the plug where the hose, &c., were attached, and in 17m. 17s. from the fire having been lighted, the engine was throwing a good stream through a 1in. nozzle.

The engine threw streams varying from 1-64th of an inch in diameter up to 1¼ in. diameter, with water pressures varying from 55lb. on the inch up to 95lb., and the steam in the boiler varying from 80lb. to 120lb. The various trials gave great satisfaction to all present, and the engine worked well and steadily. The time, &c., were carefully noted by Mr. Chas. F. T. Young, C.E. At the conclusion of the steam-engine trial, some of the new patent hand-pumps and engines of Mr. Roberts, made for the East Indian Railway, were tried with very satisfactory results.

CONGRESS OF MECHANICAL ENGINEERS, LIVERPOOL.

The annual provincial meeting of the members of the Institution of Mechanical Engineers commenced on Tuesday, in the Concert Room, St. George's Hall, Liverpool. The meeting was numerously attended, and the chair was occupied by Mr. William Clay, in the absence of Mr. Robert Napier, of Glasgow, the President, who was detained at Buxton on account of bad health. Among those present were Messrs. H. C. Beloe, Thomas Duncan, John A. Tinne, — Beloe, jun., Bright, J. Carlis[illegible] J. Hay, J. Vernon, Horman, Plumb[illegible] ham, &c. &c.

The first Paper, which was read [illegible] was "On the Construction of Ir[illegible] John Vernon, of [illegible] Sons, of this tow[illegible] culties which a[illegible] as a material f[illegible] to show the [illegible] ing out that [illegible] cheapness, [illegible] cargo by [illegible] strength [illegible] iron has [illegible] constru[illegible] applied [illegible] once a[illegible] out h[illegible] The I[illegible] ment[illegible] const[illegible]

to be registered A 1 at Lloyd's for twelve years, or for twenty years on the books of the Liverpool Underwriters' Association. The various details of construction for the different portions of the ship were clearly shown by numerous large and distinctly drawn diagrams. The "Great Britain" was referred to as an illustration of the strength and durability of iron ships, which had been exposed to the strain of being a stranded vessel for nearly twelve months in Dundrum Bay without having sustained any material damage, which it was stated could not possibly have been sustained by a wood-built ship. Reference was also made at considerable length to the iron-built screw collier ship "Anne Vernon," which, from its construction, is adapted to receive water as ballast, in water-tight compartments in the lower portion, by which the water can be retained as ballast when the vessel has no cargo, or pumped out when cargo is but on board. Bourne's Indian River Train was also explained at considerable length. These, it was stated, had not turned out quite so satisfactory as had been expected. The question of masts, yards, and rigging being made of iron or steel, by which a large saving of weight, amounting, in a 1,200-ton ship, to about 17 tons if steel were used, by which a considerable saving in the quantity of ballast carried may be effected.

A considerable amount of discussion followed the reading of this Paper, in which most of the speakers alluded in terms of approbation to the painstaking and intelligence with which the subject was treated, and of the amount of information which had been conveyed. The thanks of the meeting were cordially voted to Mr. Vernon.

The second Paper was "On the Effects of Surface Condensers on Steam Boilers," by Mr. James Jack, of Liverpool. It was read by the Secretary. The Paper referred at considerable length to the effect of using salt water in boilers, by which an incrustation of the boilers was produced, whereby the power of transmitting heat was greatly impaired. This incrustation, it was shown, would be in a great degree got rid of by the use of distilled water. The use of this kind of water, however, had been found to cause considerable chemical action on the surface of the metal of the boilers, by which it was corroded and pitted, particularly near the points where the heat was most directly brought in contact with the boiler.

A lengthy conversation ensued, in the course of which it was stated by several of the members that it is highly desirable to ascertain with accuracy what is the immediate cause of this destructive action, with a view to discover what metal is most suitable for the construction of surface condensers. Thanks were voted to Mr. Jack for his interesting Paper.

The third Paper was "On the Mechanical Features of the Liverpool Waterworks," by Mr. Thomas Duncan, of Liverpool. This Paper gave a detailed account of the nature of the waterworks at Rivington and its neighbourhood. The gathering ground of the water extended over about 10,000 acres, the water from which is retained in several reservoirs. These reservoirs, when full, are calculated to contain 3,000,000,000 gallons. The water is passed through filter beds, six in number. From the filter beds the water passes into the pure-water tanks, and thence by cast-iron pipes, with a break at a a principal reservoir at Prescot, and from that to the different subsidiary reservoirs in Liverpool and its neighbourhood. The Paper further described the various apparatus applied at different points for regulating the supply throughout the town. It also detailed the extent and mode of working the old system of wells, by which the water was previously supplied to the town; and likewise explained the mode in which the supply of water is distributed in the case of fires, which it explained to be generally on the gravitation principle, engines being but rarely used.—Thanks were voted to Mr. Duncan for his valuable Paper.

The members of the Institution then proceeded to the Prince's Landing Stage, where they went on board the steam tender "Satellite," and steamed up the river to the Herculaneum Dock, where they landed, and were conducted to the Mersey Steel and Iron Works. Here a sumptuous collation was served to about 200 of the members of the Institution, Mr. Clay presiding. Mr. S. Lloyd, one of the ex-Presidents of the institution, proposed "The health of Mr. Clay," and in the name of the members thanked that gentleman and his partners for the manner in which they had been treated. The company proceeded to view the works, and inspect the many and interesting operations which were in progress. In the first instance, they visited the extensive fitting shop, in which they witnessed the planing and turning of the stem of the "Agincourt," after having been forged and bent. In the fitting shop the visitors also saw and inspected with much interest some extensive apparatus for cutting and turning. Their attention was also attracted by the stupendous "Horsfall gun" and the "Prince Alfred gun." They also inspected a specimen of Clay's patent breech-loading field-piece, which was in the shop. From the fitting shop the party proceeded to the "forge," where they witnessed the operation of one of the numerous steam hammers with which the establishment is so extensively provided. The one referred to was an 8-ton hammer, falling through a space of 6 ft. Their attention was next directed to the operations for the erection of another and very large steam hammer, the preparations for which are very far advanced. When completed, this will be the largest steam hammer in the kingdom. Some idea of its magnitude and power may be formed from the annexed details:—The anvil block, or portion on which the anvil rests, is a solid casting which weighs no less than 62 tons of iron. The hammer will weigh 14 tons, with a fall of 10 ft, by which a blow of almost inconceivable force will be obtained. From the forge the party passed to the rolling mills, and witnessed some of the vast operations which are carried on there. The mill for rolling "armour plates," although sufficiently advanced to be in motion, was not so far completed as to enable them to roll any of the armour plates.

The second sitting was opened on Wednesday morning, at ten o'clock, Mr. William Clay, of the Mersey Steel and Iron Works, President of the Local Committee, again occupying the chair.

The first Paper read was "On the Mechanical Ventilation and Warming of St. George's Hall," by Mr. William Mackenzie. The Paper minutely described the system of ventilation invented by the late Dr. David Boswell Reid, who originated the ventilating and heating apparatus by which the building is regulated in its ventilation and temperature, and which was fitted up in its leading features under the immediate superintendence of Dr. Reid, St. George's Hall being the only building in which that system has been completely carried out. In practically carrying out that system several improvements naturally suggested themselves. Conspicuous among the leading features of this system of ventilation were the introduction of means by which draughts are altogether avoided, or so regulated as to be completely under control. This is accomplished by bringing the whole supply of air into one chamber, in which it may be modified in temperature to suit any desired purpose. Preparation is also made for securing a certain amount of humidity, by bringing it in contact with moisture, so as to keep the air in a condition at all times suited to the convenience of those who are assembled in the building. The Paper was profusely illustrated by well-executed diagrams.—After this Paper had been read some discussion took place, in the course of which it was stated by several members that the ventilating system of St. George's Hall is, taken all in all, the most perfect of any building in the kingdom. The thanks of the meeting were cordially awarded to Mr. Mackenzie for the Paper which he had supplied.

The second Paper was "On Machinery for the Manufacture of Plate Glass," by Mr. George H. Daglish, of St. Helen's. It, like the other Papers, was read by the Secretary, and copiously illustrated by diagrams. The Paper, after briefly alluding to the general processes and materials employed in the manufacture of glass, described the recent improvements which have been introduced in the manufacture, and then at considerable length described the machinery by which plate glass, after being cast and annealed, is polished and regulated. It was stated that, in the process of grinding and polishing, about 40 per cent. of the whole material is wasted. The polishing apparatus used at the Ravenshead Plate Glass Works, at St. Helen's, was stated to be capable of preparing and finishing from 1,200 to 1,500 square feet per week.—In course of the discussion which ensued on the reading of the Paper, it was shown that the purest colour of the glass, of which several specimens were shown, was made from French sand.—At the conclusion of the discussion, the thanks of the meeting were voted to Mr. Daglish for the Paper which had been read.

The third Paper was a "Description of the New Iron Works at Grosmont," in the Cleveland iron district, about seven miles from Whitby. This is a hotblast works. In each furnace the apparatus is sufficient to blow 7,000 cubic feet of highly-heated air per hour through the tubes by which the furnaces are kept in blast. The Paper was very technical and minute in its details, and a considerable amount of discussion took place in reference to several of the points alluded to.—At the conclusion of the discussion, a vote of thanks was passed to Mr. Coulthard, the author, and thanks were also most cordially voted to Mr. Clay for his conduct in the chair.

Soon after one o'clock the members embarked on board the steamer "Satellite," placed at their disposal by Mr. C. MacIver, and proceeded to the Canada Dock, where they inspected the 100-foot gates, the swing bridge, and a capstan, moved by hydraulic power. They went on board the "Asia" and the "Australasian," and were conducted over the works of the British and North American Steamship Company by Mr. MacIver. Reembarking, the next visit was to the shipbuilding yard and ironworks of the Messrs. Laird. The party was met by Mr. John Laird, M.P., who was accompanied by Mr. Whitworth, the inventor of the rifle which bears his name. Her Majesty's armour-plated ship "Agincourt," the powerful steam ram recently launched, a similar one on the stocks, and other vessels in course of construction, were inspected with much interest, as also were the various machinery departments. There was shown in action the hydraulic press, of immense power, by which the armour plates (made at the Mersey Steel and Ironworks) are bent into the required shape to fit a ship's side. After leaving the works of the Messrs. Laird, the visitors landed at the Woodside stage, and thence made an inspection of the Birkenhead Docks, the chain-testing machine belonging to the Mersey Docks and Harbour Board, the great float and the 100-foot gates, and the Messrs. Bibby's copperworks. After this they returned in the "Satellite" to Liverpool.

ENGLISH ARMOUR-PLATES AND AMERICAN IRON-CLADS.

The following letter appeared in the *Daily News*, of July 31, 1863:—

Sir,—Though discussions in Parliament have now for a season ceased, the following facts and inferences, bearing on the state and character of our artillery and armour-fleet at the time of its rising, may yet be of interest to some of your readers, or even of use for grave reflection during the recess, should you deem them worth insertion in your columns.

On the premises of the Iron Ship-building Company, at Blackwall, may be seen near the landing-place where the "Minotaur" is building, an armour-plate erected on its edge, with an inscription beneath it. The plate is, as usual, 4½ inches thick, and now but half its original length. It was made on the premises for the "Royal Oak," and was casually taken last summer from a lot of about 40 similar ones to be tested at Portsmouth by the 68-pounders of the "Excellent's" gun-boat "Stork," being fixed for the purpose on the side of the "Sultan," a worn-out line-of-battle ship, with a timber scantling of 22 inches. Select shot, both of cast and wrought iron, were fired at right angles against it from a distance of only 50 yards with 22 lb. charges of powder, the fullest service charge being 16 lb. only, and by very careful measurement the following are the effects produced under these extreme conditions. The cast-iron shot went to pieces as usual, leaving a crater 8 in. in diameter like itself, and 2¼ in. deep. The wrought-iron shot, still entire, after entering the plate expanded to a diameter of 9 in., and has thus imbedded itself firmly into the face of the plate, like the setting of a jewel; it projects 3¼ in., and has flattened 2¼ in. Each shot has produced a bulge at the rear of the plate; that of the cast-iron protrudes 2½ in. like the depth of its crater in front; that of the wrought-iron protrudes 3¼ in. At the apex of each bulge are open radiating cracks, not wide, not extensive, nor connected, but varying, and how deep could not be measured; but, besides these, neither in front nor rear are there either cracks or other indications of any injury to the metal, even between the two shot-marks, which are less than 8 in. apart.

The solid-shot smooth-bore 68-pounder of 95 cwt., the extreme and exceptional powers of which in powder, shot, and distance, are thus practically to be seen stamped upon the armour plate at Blackwall, is the most destructive gun which either the land or sea service of England possesses; and when the writer was first informed of the above limit to its powers by the party who thus put them to proof, it was added, in reply to a direct question, that not a splinter of any consideration was produced by these exceptional shots inside the ship—so complete is the protection afforded by such plates against

such guns, even within the sides of an old dried-up hulk.

Now, the first practical inference to be drawn from these facts, on this side of the water, seems to be this:—Assuming the timber scantling of the "Gloire" to be no thicker nor sounder than that of the "Sultan," and French 4½ in. armour plates to be equal to British, then, so far as regards the power of British guns by sea or land to stop her, that redoubtable exemplar of modern naval power, or any or all of her full-armoured consorts, may enter Portsmouth Harbour at option, and having there wrought her wicked will, may again retire with scarcely more apprehension of fatal casualty or serious injury than if going in and out of Cherbourg. Of course, the harbour, like the Thames, might be blocked, or "butting," or boarding, or fire-rafts, or torpedoes, or stinkpots, or other means, might be employed for destruction or capture in so insolent a case; but strictly confining the contest to the power of artillery alone, as it exists in the British services, then such casual damage only as could be effected by firing into the ports of a frigate 200 yards off, and covered with smoke, would be the limit of injury to be inflicted through the mailed sides of the intruder, even if the guns were already manned in expectation of the visit; Portsmouth serving specially to exemplify this pleasing hypothesis, as none of its batteries could command the destruction of such a frigate by firing down through her unarmoured decks. And yet it is undoubtedly true that the equally low forts of Charleston victoriously repulsed, and even sunk one of the assailant Federal iron-clads from a distance stated as not less than 900 yards. Let us see the reason why.

In an Admiralty blue-book report (No. 737, of 1850), may be seen the complete drawings and detail account of firing 32-pounder and hollow 8-inch shot from a range of 400 yards at a riveted mass of 14 iron plates 6 in. thick in all, bolted on a timber scantling 2 ft. thick, like that at an 80-gun ship's lower deck, and of the practical destruction of this mass even by guns of such low power. This experiment, made from the "Excellent," in 1842, and in character and result more than once recently repeated, was ordered in consequence of reports from America that effective protection from heavy artillery had been obtained at certain trials of the same sort there; and the adoption of armour-plating of similar construction for all but one of the assailant iron-clads at Charleston, seems to show how far more satisfied our Federal friends must have been, at least up to the time of their repulse, with their own mode of putting such combinations to proof, than we were with ours. For instance—

The "Keokuk," which was sunk, is described to have had her fixed turrets built of ordinary ¼-inch plating, on the frames of an ordinary iron steamer; this was surrounded by ⅝ bar iron, 4 in. wide, placed on edge in the intermediate 1½-inch spaces, filled in with pine, and the whole clothed with five layers of ⅝ plates. The wood and iron combination of her turrets was thus 7⅝ in. thick in all, and that of the vessel herself could hardly have been more.

The "Passaic," described as an improved "Monitor," and the type of six of her Charleston consorts, was protected, apparently turrets and all, by a riveted mass of eleven ⅝ plates, or 6⅞ in. thick in all.

The "New Ironsides," the alone exception, no known description of which has, I believe, reached this country, seems to be an armour-ship of the European broadside type; but from the accounts of the action she appears to have undergone no test whatever of her powers either way.

Thus, if we even allow the same 2 ft. of timber beneath the armour of these iron-clads, as in our own experiment of 1842—and we have no notice that there was any timber—the thickness of the riveted mass practically differs so little in the two cases that the drawings in the above blue-book may safely be taken to represent the type of destruction inflicted on eight of the assailants by the guns of Charleston, assuming them to have been no heavier than those then in use by the "Excellent"; while the powerlessness of our now heaviest service gun against the solid 4½-inch Blackwall plate, proves the practical difference between the European and American systems of constructing ship's armour in quite sufficient contrast to account for the paradox which sent us to seek for "its reason why."

But here it is necessary to prevent the serious misconstruction that, because solid plates such as that at Blackwall protect, where protected at all, the sides of our own armour-ships, therefore any one of them, without distinction, and with equal impunity from guns not commanding her decks, might be sent to return at Cherbourg the supposed visit of the "Gloire" to Portsmouth; or even that our whole number, as now completing, could for a like reason be sent to force such forts as those of Charleston. For however naturally it may seem to have been intended to convey such inference from what has been stated, that which now follows will sufficiently show it to be erroneous in itself, and not consistent with a sound professional judgment in him who should sanction it. For instance—throughout all other navies it is now known that the "Warrior's" foremast marks out for aim a target no less than 81 ft. long; and her mizenmast another no less than 96 ft. long; being a length in all of 177 ft. from her water-line up to her hammock-rail on each broadside exposed to an enemy's fire, which has no protection at all, and where the men and guns may therefore be taken to have been already stripped of all armour, whether by foe or friend, before the first shot of an action is fired. The extent of surface thus exposed is covered for the greater part, where the men on the gun-deck fight, with no more than a single ⅝ plate of iron; and as no practical addition is made to the resistance of such plates by that detached 2 in. lining of wood, which only gives a flush surface for paint inside the ship, there is little doubt that this fighting portion of the structure would, if it were tried, be penetrated by a steel bolt from the ordinary Whitworth rifle. Fourteen inches of combustible teak protect the upper-deck guns throughout; and the now well-known accident to the "Defence" has shown that the ⅞-plating which alone covers the above length of hull from below the level of the main deck down to the water's edge is destructible by any blow such as that of a bower anchor swinging when "a-cock-bill" from a few feet out of the perpendicular. These unarmoured parts are armed with one-third, or 14 out of the whole 40 guns, requiring, on the usual rough estimate 140 men to fight them; and as the mainmast equally marks out the central 26-gun battery, 208 ft. long, where ship, guns, and men are completely protected with plates of the Blackwall build, no enemy, whether from ship or shore, could desire distinctions more clear, even above all the smoke of action, as to what portions of such an antagonist he should and he should not concentrate his fire upon. He also specially knows that all which is vulnerable in the steerage gear and screw—the motive and directing powers—is contained within the thin sides of that aftermost 96 ft. box-target.

These characteristics as accurately describe the "Black Prince" as the "Warrior." In their now altered sister, "Achilles," they apply to the upper deck only, her ten unarmoured main-deck guns being altogether removed, and the hull itself being plated from below the water-line upwards throughout the 81 ft. afore and the 96 ft. abaft the central 26-gun battery, as high as the level of the main-deck platform. What a pity that a few steps further in the same wise direction have not made the "Achilles" our one complete and satisfactory specimen of a broadside armour-ship. The "Defence" and "Resistance" are in fighting features precisely as the "Warrior" on a smaller scale, their masts equally performing the office for an enemy of marking off their two unarmed parts from their central armoured one, which, as before, protects but two-thirds, or 12 out of their whole 18 guns, each. The same office is again performed by the masts of the "Hector" and "Valiant," but with the improvement that their entire main-deck batteries of 32 guns each are plated, leaving exposed at each end about 40 feet of hull below the main-deck platform to the waterline, a reverse variety of the plan of "Achilles." It is thus seen that no enemy from ship or shore need reserve his fire as at Charleston until the approach of such ships within 1,000 yards; but with a modified exception in "Achilles," that each of them presents a large well-distinguished surface, armed and unarmed, weaker than wood to resist the impact of shot, and liable to fatal destruction from as far as any sort of missile can deliver on it a blow equal to that of her own anchor when its surge from the gunboat broke in the bow of the "Defence."

The yet unlaunched "Minotaur," "Agincourt," and "Northumberland," armoured throughout, would present at Cherbourg sides as impenetrable to the British 68-pounders as the "Gloire" at Portsmouth; but aside from the moot question of whether our nearest neighbours do or do not possess artillery more destructive than our own, it is certain that Charleston was defended by modern guns of far greater power, both rifled and smooth-bore. If, therefore, we assume as a standard of the heaviest future artillery—and many will find this too moderate—the same destructive force in solid shot, spherical or conical, as was temporarily exhibited by the 12-ton smooth-bore gun when fired at the "Warrior" target in April and May, 1862, we shall find that the three above-named ships, though armoured throughout, could not maintain a contest at close quarters against such guns; but that against such guns at equally close quarters all seven of the first named ships could successfully resist, as far as regards their armoured portions—a paradox which will again be fully accounted for by the following "reason why."

The above gun, now doubly defunct, when used as aforsaid against the "Warrior" target, was fired from 200 yards with charges of 50lb. of powder behind solid round shot of 156 lb., none of the three shot thus fired producing any serious effect on the inner skin of iron representing the ship as distinct from her armour, but all of them more or less plugging the clean apertures by which they entered through the plates into the backing, and on taking the target to pieces it was ascertained of the shot which entered deepest that it had penetrated behind the plate but 13 inches, leaving five inches of the backing between it and the ship proper into which in the words of the report, "no fragment of the shot had forced its way." But on the 7th of July following, the same gun, under all the same circumstances, sent two shot out of three, right through an equally faithful target of the "Minotaur" and her two sisters the fourth failing to follow suit only because the gun itself burst in firing it; and the details of this trial, as given in the report of the Royal Artillery Institution, are summed up thus:—"From the result of this experiment it is plain that the powers of resistance of a structure such as the "Warrior," are superior to those of a vessel constructed on the plan proposed for the "Minotaur." The additional inch of iron in the thickness of the plate is clearly no compensation for the reduction of nine inches, or half the thickness, of teak backing."

This recognized "result" was then officially followed up by overtures to the builders of the three ships to restore the 18 in. of backing, in which case they must have proved more complete and satisfactory armour ships than even the "Achilles" if fully altered; but the expense, and doubtless the unavoidable exposure of the alteration, decided on their completion as first begun, viz., not with the successful 4½ in. plates over 18 in. of backing, as in the "Warrior" and six first vessels; but with 5½ in. plates over only 9 in. of backing—a now proved inferiority, which cannot be disregarded, should these otherwise noble ships come under fire of any guns of equal penetrative force with that of the above 12-ton smooth-bore, and all the more to be regretted because a similar comparative trial to detect error could have cost the country no more had it been made before, instead of many months after, the closing of the contracts for these ships.

All the ten above-named are armour-ships of iron; the "Royal Oak" and four others, with 32-gun batteries each, and hulls completely mailed, except on upper decks, are armour ships of wood—English "Gloires," with sides equally penetrable or impenetrable as their French exemplar under similar circumstances by similar guns. Here no representative target has yet told us what are their real resisting powers, positive or comparative, when tested as the armour combinations of the "Warrior" and "Minotaur" have been by the above 12-ton representative of modern artillery force in solid shot. Yet they constitute the most compact portion of our armour fleet, and together mount more armoured guns than any other section of it capable of acting together. But while there seems some subtle temptation to strain for an increase of these ships, with their yet unknown powers of resistance even against heavy round shot, their material will be seen to render them peculiarly destructible by those explosive rifled projectiles which up to a recent date all armour-ship warfare seemed likely to be exempt from. For instance—

In November last the whole question of the powers of resistance by European armour-ships against modern artillery assumed entirely new features before Mr. Whitworth's successful experiments with shells. The "Warrior" target, when clothed with only 4½-in. plates, had, as we have seen, successfully resisted complete penetration by the solid shot of the 12-ton smooth-bore at 200 yards, and afterwards was pierced for the first time by the similar 22-ton Horsfall gun, firing a solid round shot of 280 lb. with 74 lb. of powder from the same range. But in November last a "Warrior" target clothed with 5-in. plates was equally pierced completely through by a shell of 130 lb. with 27 lb. of

powder from Whitworth's $7\frac{1}{2}$ ton gun as a distance of 800 yards, and at 600 yards his $3\frac{1}{2}$ ton gun firing a 70 lb. shell with but 12 lb. powder, penetrated the $4\frac{1}{2}$ plate and entire backing of the same target as far as, but not through, the iron skin of the ship; these results showing incontestably that, whenever we may be permitted to have them, guns of this description of a perfectly manageable weight for broadside armament may be effectually used with shells against armour-ships, protected even with Blackwall plates. And the revolution thus effected is no less remarkable than generally unexpected, because the shells require no fuses, and in respect to temper are superior in penetrative qualities to solid shot of the same material.

These proofs go to show that both the "Warrior" and "Minotaur" mode of armour can no longer protect against this complete restoration of effective shell fire, to be no doubt developed still more formidably; but as armour-ships of iron, they possess an extent of security against such missiles from which the "Gloire" and "Royal Oak," armour-ships of wood, of whatever rank, are from the nature of their material debarred. There is before me a copy of the official drawing, made when the November target was taken to pieces, of the effects on its inner structure of Mr. Whitworth's shells. That drawing shows not only how effectively the iron skin of the ship proper has limited inside the range of destructive explosion, but the angle at which the armour-plate itself is shown to have been blasted away around the interior of each aperture directly points to the actual extent of woodwork behind the plate, which must have been more or less shattered or destroyed but for its support and compression under the powerful system of bolting between the inside iron skin and the outside armour. In the target in question, as in all armour-ships of iron, this woodwork behind the armour is only its backing, and if with the plate itself it were entirely blasted off by shell explosion, a sound and strong ship of iron might still remain. But the woodwork behind the plates of an armour-ship of wood is not backing only, it is essentially the timber of the ship, the sole strength of her fabric, having no support but from itself, and with no incombustible inner lining; and to destroy and shatter it with shells is, *pro tanto*, to shatter and destroy the ship herself and those within her—probably to burn her as at Sinope—as effectually as in the days when outer plankings of wood did their best to protect from shell-fire the similar wooden timbers beyond them. Is it, then, well and wise towards the country—can it be just and true towards its navy—to meet this complete restoration of destructive shell-fire by increasing our force (?) of such armour-ships as are most exposed to be destroyed by it, in preference to those which are least? When 5-inch armour can already be pierced like 5-inch cheese, is it not a time to increase rather than abolish the protection of that inner skin of iron which, even at its present $\frac{5}{8}$ thickness, is seen by all who will look very sensibly to limit the splintering and destruction of these iron-plate shells? But if there be real honest doubt, why not remove it openly? Why not take warning before too late again from the "Minotaur" case? The armour-ship of iron has had her target before these shells, and the big shot, too. Try the same fire on an equal target of the "Royal Oak," and let open, not secret results, as in former times, decide this revived strife about the safest material for our future armour fleet.

Whether the walls of Cherbourg or Charleston be as yet defended by armour-plate shells is probably not fully known here; but it is quite certain that they will be, as in due time may be those of Portsmouth, too, as well as all armour fleets; and in that day it seems likely that ships between themselves, and in intercourse with fortresses, will, according to relative force, observe towards each other much the same amount of respect as in past times; speed in almost all cases constituting a chief standard of relative war merit. But of the plans now before us as yet to be developed, the cupola ship bids higher than any other, as against both ships and forts, to become the type of future maritime strength. With unapproached facility for carrying and working the heaviest practicable guns, able to be burthened with the heaviest reasonable armour, freed for equipment with highest powers of speed by steam and sail, and with promise of superior seaboat qualities, the cupola ship, as a true British invention, claims every support and encouragement the country can extend to her talented inventor in his arduous struggle for her speedy, complete, and successful development as the future floating symbol of our naval power.

The difficulty of dealing with the theme of this letter at all, without testing the soundness of each main link of that complicated and scarce connected chain we have now been four years weaving, with so much cheap self-gratulation, and such substantial expense, past, present, and future, may, I trust, be accepted in apology for its length by yourself and readers.

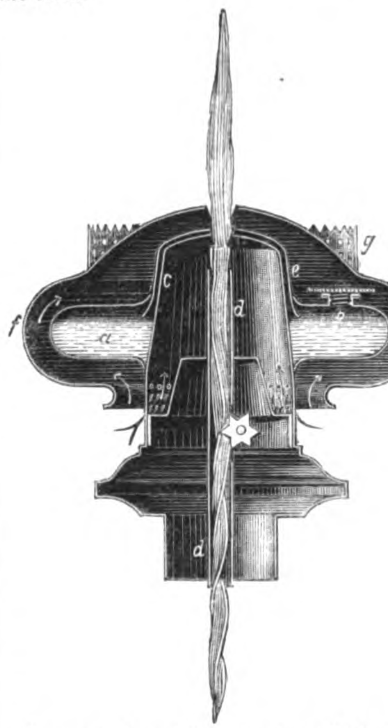
I am, &c.,
E. Pellew Halsted, Rear-Admiral.

SCHOMBURG AND BALDAMUS'S IMPROVEMENTS IN LAMPS.

The following invention for improvements in lamps has been patented by Messrs. R. Schomburg and A. Baldamus, of Lorrimore-road, Surrey.

The invention consists in leading the vapour from water to all kinds of oils while burning in lamps, whereby combustion is rendered more perfect and the purity of the light increased. The heat generated when the wick is lighted causes the vapour of water to ascend in a hollow cone or conical chamber round the wick tube and issue in contact with the flame about or above the point of its generation. A thin film of vapour rises from the water vessel up a narrow channel or space between two cones or conical caps with apertures through or between which the flame passes. The water vessel is by preference surrounded by another vessel or chamber, between which a passage is formed through which air passes to the flame.

The accompanying drawing is a longitudinal section of so much of a lamp as is necessary for showing the method of carrying the invention into effect.



a is a vessel containing water, which is admitted through the opening *b*, closed by a screwed or other stopper; *c* is a hollow cone or conical chamber surrounding the wick tube *d*; *e* is an inverted cup-shaped or conical vessel placed over the cone *c* in such manner as to leave a narrow channel or space between it and the cone *c*; *f* is an outer case through which air passes to the outside of the flame. The heat from the flame causes vapour from the water in the vessel *a* to rise through the space between the conical caps *c* and *e* to the flame. Atmospheric air is led to the flame through the spaces *c* and *f*; *g* is the support or holder for the chimney. The other parts of the lamp are of the ordinary construction. Instead of the vapour from water being generated by the flame of the lamp, it may be otherwise generated and conveyed to the flame.

NEWTON'S IMPROVEMENTS IN TRANSMITTING POWER.

Letters Patent have been granted to Mr. A. V. Newton, of 66, Chancery-lane, for the invention of improved apparatus for the transmission of power.

This invention relates mainly to a novel arrangement or combination of gearing applicable to the transmission of power to steering, hoisting, or hauling apparatus. The invention may be described as consisting in the arrangement of two cog wheels with a different or equal number of teeth—one being firmly secured to the drum of a steering, hoisting, or hauling apparatus, and the other being stationary; or when the apparatus is to be used for hoisting or other purposes, the

FIG. I.

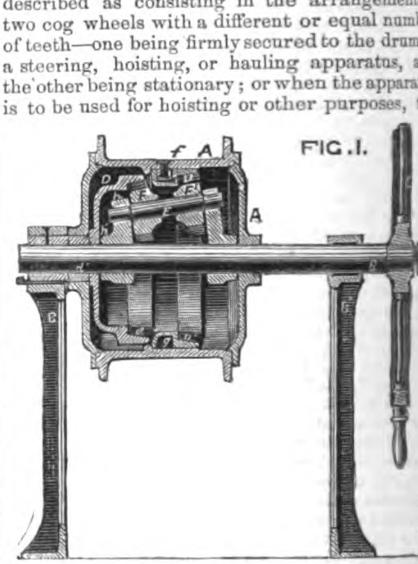


FIG. 2.

former wheel being stationary and the latter secured to the drum or drum shaft. In combination with these cog wheels are pinions, having an equal or different number of teeth, and attached to a tumbling shaft, which is carried round the drum shaft in such a manner that on rotating the wheel or drum shaft by the combined action of the two pinions on the tumbling shaft and the differential wheels, a slow rotary motion is imparted to the drum (or to the drum shaft when used for hoisting or other purposes). The power applied to the wheel shaft or to the tumbling shaft is multiplied in proportion to the number of teeth of the gear wheel which is fast to the drum, divided by the difference between the number of teeth of the said wheel and that of the stationary wheel; or if the number of teeth of these cog wheels is equal, divided by the difference

between the number of teeth of the two pinions on the tumbling shaft, it being understood that a difference must exist either between the number of teeth of the cog wheels, or of the pinions, or both.

The invention is represented in the drawing as applied to steering apparatus: fig. 1 being a longitudinal central section of the apparatus, and fig. 2 a transverse vertical section of the same.

A represents the drum on which is wound the rope or chain that governs the position of the rudder when the apparatus is used for steering, or from which the load is suspended, when the apparatus is used for hoisting or hauling. This drum (which may be made of cast iron, wood, or any other suitable material) turns loosely on the shaft B, to which the steering wheel C is firmly attached, and which has its bearings in standards B^1. The drum A is hollow, and a cog wheel D with an internal gear d is firmly secured in the interior of the drum. This cog wheel is provided with a hub which projects through the side of the drum, and which is firmly keyed to one of the standards B_1, being bored out to fit the shaft B, and turned off on its outside to form a good bearing for the drum, so that the drum rotates while the cog wheel D remains stationary. D^1 is an internal gear or a rim provided with teeth on its inside and turned off, so that it fits nicely into the drum. It is prevented from rotating independent of the drum by three (more or less) stops, which are secured to the inner surface of the drum by screws, and which project into a groove turned into the rim D^1. This groove is provided with three (more or less) abutments. If the spaces between the abutments and stops where left empty, the drum impelled by the sudden motions of the rudder would fly in either direction, bringing the stops alternately in contact with the abutments on either side. Or if the rim D^1 were rigidly attached to the drum, the sudden motions of the rudder would cause an equally sudden jar of the cogs, rendering them liable to get broken or out of order. To avoid these disadvantages, the spaces between the abutments and stops are filled out with india rubber or other elastic material, and by these means the cogs of the gear wheels are saved from injury. E is the tumbling shaft which has its bearings in arms h projecting from hubs that are firmly keyed to the shaft B. This shaft carries two pinions—the pinion F to gear into the cog wheel D, and the pinion F^1 to gear into the cog wheel D^1. Instead of one tumbling shaft with pinions, two or more such shafts, each with its own pair of pinions, might be employed, as indicated in fig. 2 of the drawing. The operation is as follows:—If the cog wheel D has 36 cogs, and the cog wheel D^1 40 cogs, and the two pinions F, F_1, which are of equal diameter, each 12 cogs, and if the shaft B is now rotated until the tumbling shaft has made one complete revolution round the centre of the shaft B, the pinion F by the action of the cog wheel D will make 36-12ths = 3 complete revolutions, causing the pinion F^1 to make the same number of revolutions, or to progress 36 teeth by the time the tumbling shaft has returned to its original position. The drum therefore is compelled to rotate for the distance of 40 — 36 = 4 teeth for each revolution of the tumbling shaft, or to make 1-10th of a revolution for each revolution of the steering wheel. It is obvious that by decreasing or increasing the difference between the number of teeth of the two wheels D, D^1, the motion of the drum for each revolution of the shaft B can be decreased or increased at pleasure, and in the same ratio the power exerted by the man at the steering wheel can be increased or decreased as much as may be desired. A strain exerted on the drum will have little effect on the shaft B, because the pinions F, F^1, have the same diameters, and the entire strain will be sustained by the stationary wheel D.

The same apparatus may be used with equal advantage for hoisting or other purposes, and the wheels D, D^1, may be made with an external gear, in which case the the wheel D^1 would be secured to the shaft B, and the tumbling shaft would have its bearings in the heads of the drum.

UTILIZATION OF SEWAGE.

IT is well known (says Liebig, in a letter recently written by him to some of the London papers,) that the manufacture of artificial manure is based on the doctrine that the nourishment of all cultivated plants consists of inorganic or mineral substances. Manure consisting of organic substances can be produced by the agriculturist only. The farmer produces farmyard manure; the manufacturer, on the other hand, mineral manure, with which he furnishes the farmer with those efficient elements wanting in stable dung. The most important fabrication is that of superphosphate of lime. The question of immediate importance to be decided is the value to the farmer of the sewerage used, and it is easy to find this by comparing the sewage matter with guano, the effect and price of which are known to the farmer, and of whose value he is able to judge. The problem to be solved is, therefore, how much of the efficient elements of guano a farmer can convey to his field in a ton of sewage; or how many gallons of sewer water are equivalent to a cwt. of guano. Regarding the component parts of the best sorts of guano we have certain and reliable data—those relating to sewer water are less so; but we might long ago have been fully informed of its average contents if, last year, at the mouth of each sewer in London, five gallons of water had been collected morning and evening every day during the week, and at the end of the 7th day one gallon of the collected seventy gallons subjected to chemical analysis. It would be necessary, of course, to determine as nearly as possible the quantity of water discharged at each sewer. Lacking more certain data, I take Professors Way's analysis of sewer water, which this most reliable chemist made at the request of the General Board of Health.

I reckon that Peruvian guano contains 14 per cent. of nitrogen (= 17 ammonia), 12 per cent. phosphoric acid, and 6-10ths per cent. of potash. Professor Way analyzed the water of two sewers, one in Dorset-square and the other in Barrett's-court, and found in one gallon of sewer water—

	Barrett's-court.		Dorset-square.
Ammonia	41·18 grs.	......	17·96 grs.
Phosphoric acid	10·44 „	......	4·17 „
Potash	44·18 „	......	3·33 „

The difference in the contents of the two sewers is very great, for the first contains twenty-nine more ammonia and phosphoric acid, and fifteen times as much potash as the other. According to the analyses of Dr. Hoffman, Frankland, and others, I am of opinion that I may take the contents of the Dorset-square sewer water as the averge standard for my calculation. From the above figures it results that 101 tons (22,200 gallons) of this sewer water contains the same amount of phosphoric acid, more than three times as much ammonia, and sixteen times as much potash, as one cwt. of the best Peruvian guano.

It will be observed that there is a great difference in the proportion of phosphoric acid to ammonia in guano and sewer water. In guano this proportion is 6 parts of phosphoric acid to 8½ parts of ammonia; in sewer water this proportion is 6 parts of phosphoric acid to 26 parts of ammonia. The reason of this disproportion in the amount of phosphoric acid and ammonia in sewer water is at once perceived, if we remember that the bones of the slaughtered animals do not find their way into the sewers. These bones are, however, the manuring matter in which phosphoric acid abounds; and their component parts, let it be well understood, must be given back to the fields if it be intended that the soil shall retain its fertility. Potash and ammonia are, according to their prices, far more costly manures than phosphates, and in many cases quite as necessary for the field as this latter can be. Potash and ammonia are wholly inefficient and useless without the presence of phosphoric acid; but with the addition of phosphates, they become efficient and valuable. The manufacturer of manure is not able to supply potash and ammonia to the farmer in sufficient quantity, and at an available price; but it is easy for him to collect the bones and make up the deficiency of phosphate by drawing it from natural sources.

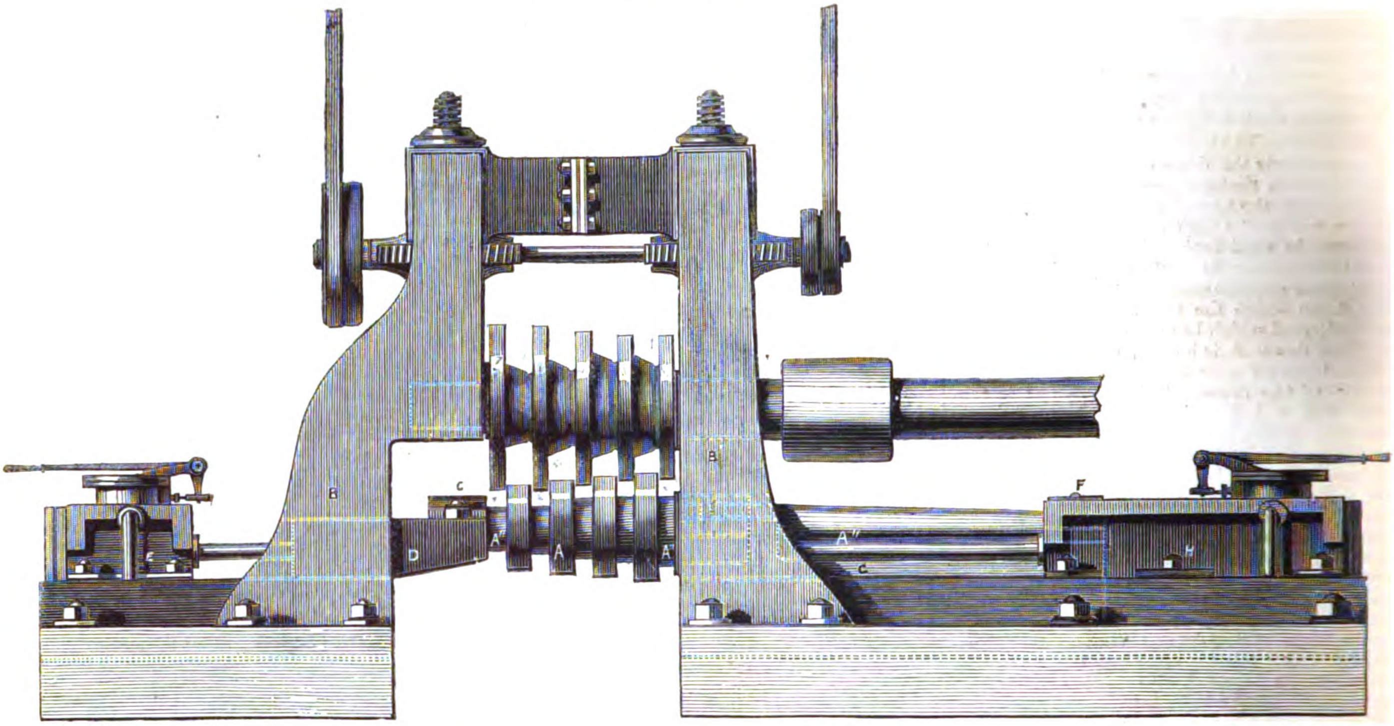
It will, I think, be now perceptible, what connection there is between the manufacture of superphosphate and the utilization of sewage. If the farmer add to the sewer water the phosphate which is wanting in it, the efficiency of the water will be increased. Thus, 101 tons of sewer water, to which 120 lb. of superphosphate have been added, are equivalent to 305 lb. of Peruvian guano, and the value of the sewer water will be 305 lb. of guano, at £13 12s. 6d. a ton, 498 pence; from this subtract the price of 120 lb. of superphosphate, at £5 5s., 76 pence; which gives the value of 101 tons sewer water, 422 pence, or 4d. for one ton. It must not be forgotten, that sewerage without the addition of phosphate is of much less value, because, if the farmer were to give the soil, in sewerage, as much phosphoric acid as is in 305 lb. guano, he would have to apply 305 tons of sewer water (instead of 101 tons), which would give the value of 1½d. per ton. I am of opinion that the proportion of ammonia which is brought into the soil by dressing the land with Peruvian guano, is much too large and even noxious for future crops; but this does not belong to the present question.

From exact calculation of the liquid and solid voidings of London (the detail of which would be out of place here), we may conclude that 42 tons of ammonia, 10 tons of phosphoric acid, and 7½ tons of potash, find their way into the London sewers daily. These 42 tons of ammonia are contained in 247 tons of guano, the 10 tons of phosphoric acid in 83·3 tons guano; thus, 163·7 tons remain in which the phosphoric acid is wanting; or, what is the same thing, if to the sewerage obtained daily from London 100 tons of superphosphate of lime (at 20 per cent. of phosphoric acid) be added, the value of the daily voidings of the metropolis, or the sewage of London, is made equivalent to 247 tons Peruvian guano; or, by the addition yearly of 36,500 tons of superphosphate, we may acquire the value of 90,155 tons guano, at £13 12s. 6d. = £1,226,364. Deduct the price of 36,500 tons of superphosphate, at £55 s. = £191,628, and we have £1,036,736 as the money value of the sewage. To this should still be added the worth of the potash in the sewer water. Potash is the manure which the farmer obtains with the most difficulty; it is that element, too, which renders his stable dung (the amount of phosphoric acid and ammonia being the same) of greater value and efficacy. In 247 tons of guano about 1½ tons of potash are contained; but every day 7½ tons are obtained in the sewer water, which gives a surplus of 6 tons, corresponding to 11 tons of sulphate of potash, giving yearly 4,015 tons, which, at £18 per ton, shows a money value of £72,270. Add this to the sum above given, and we have, as real money value of the London sewerage, £1,109,006.

The surplus potash won from the sewer water daily corresponds to the amount contained in 866 tons of stable dung. Without the addition of the superphospate the value of the sewerage of London would only be £304,045. In the calculation of the value of sewer water there is one factor doubtful—viz., the absolute amount of phosphoric acid, ammonia, and potash which a ton of the said water contains. It might probably be found that some sewer water was richer, another more diluted or poorer in these component parts, but in the relative proportion I do not think that any very great difference would be found. Sewer water will, in the average, contain more potash than I have allowed for, inasmuch as the fluid voidings of horses are to be added, which increase the amount of potash. We may assume that one-third of the population of Great Britain, or ten millions of men, live on corn and agricultural produce imported from abroad. For this a pretty considerable number of millions of pounds sterling must be paid, besides another pretty considerable number which must be earned by the nation, in order to pay for the purchase of manures to produce the food of the remaining 20,000,000 of inhabitant. Many superficial observers appeal to statistics, which appear to show that much of the land yields one-third more than it did in the last century, and this is not they say a sign of decrease of fertility; but they forget at what cost their larger crops are obtained, and that they are due to an enormous expense of capital for the purchase of foreign manures. It is a sign of a poor or an exhausted soil, if, in order to get high returns, we have to add large quantities of manure from without; a rich or fertile soil does not require such an addition.

The employment of sewerage in agriculture could make it possible to bring large tracts of land into cultivation which hitherto, owing to the expense of tillage, had been laid waste and neglected; others, too, might be so improved as to make the crops remunerative, and good yields would bring in a larger revenue. The vast capital which hitherto has left the country to pay for corn and manure might be kept at home and employed for other purposes. Should the present state of trade and industry not materially change, a great part of this capital would be devoted to agriculture, and the natural consequence would be, that the i[illegible]ing population would find ample occupati[illegible]ndry. Great

LONGRIDGE'S ROLLING MACHINERY.

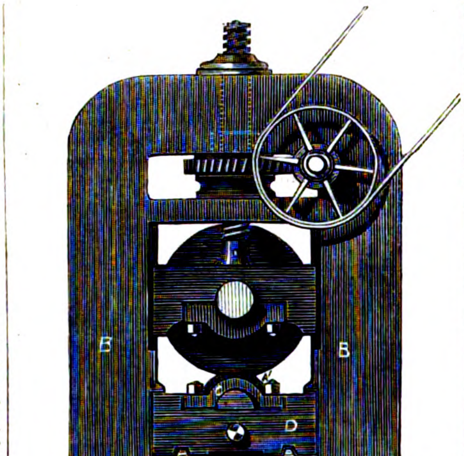


Britain is large enough, if we take the arable surface of the land, to produce all the corn and meat necessary for its inhabitants. It is neither fantastic nor ridiculous to believe that, without purchasing foreign manure, and by a judicious utilization of the sewage of towns and villages, England would be able to dispense with the importation of food from abroad. For her it would be a blessing if the application of capital to agriculture were found sufficiently profitable to awaken speculation in this direction, so that the industrial population, manufacturers, and tradesmen might devote themselves to the production of bread and meat.

LONGRIDGE'S ROLLING MACHINERY.

Letters Patent have been granted to Mr. W. S. Longridge for the invention of improvements in apparatus for rolling metals, railway tyres, boiler plates, &c., by which the patentee is enabled to roll such tyres, or sheets, or plates, or other sections of metal in the form of hoops or rings. The upper roll of his improved machinery is mounted in the manner usual in rolling machinery, and the lower roll is mounted in such manner that when the tyres, hoops, or rings are passed into or removed from the machines they are passed between the end of the lower roll and the side frame which carries the bearing of the roll.

Thus, one end A^1 of the lower roll A when in its working position, as shown, does not reach into or up to the side frame or standard B of the machine, but an intermediate or open space is left between the end of the roll and the side frame or standard sufficient to allow the bloom for the tyre, hoop, or ring to be passed between them, and inserted between the upper and the lower rolls and to be removed therefrom. The bearing C which carries this end of the lower roll is mounted upon a carriage D sliding longitudinally into or upon the frame B to and from the lower roll A, so that when it is traversed backwards from the roll the intermediate or open space referred to between the roll and the frame is left free for the passage of the bloom, tyre, hoop, or ring into or from between the rolls, as required, and when the bearing carriage is traversed in the opposite direction, or towards the lower roll, it projects inwards between the frames and receives the journal or end A^1 of the lower roll, thus forming its bearing and support, and upon which it revolves; E is an hydraulic cylinder, secured to the foundation framing of the machine for the



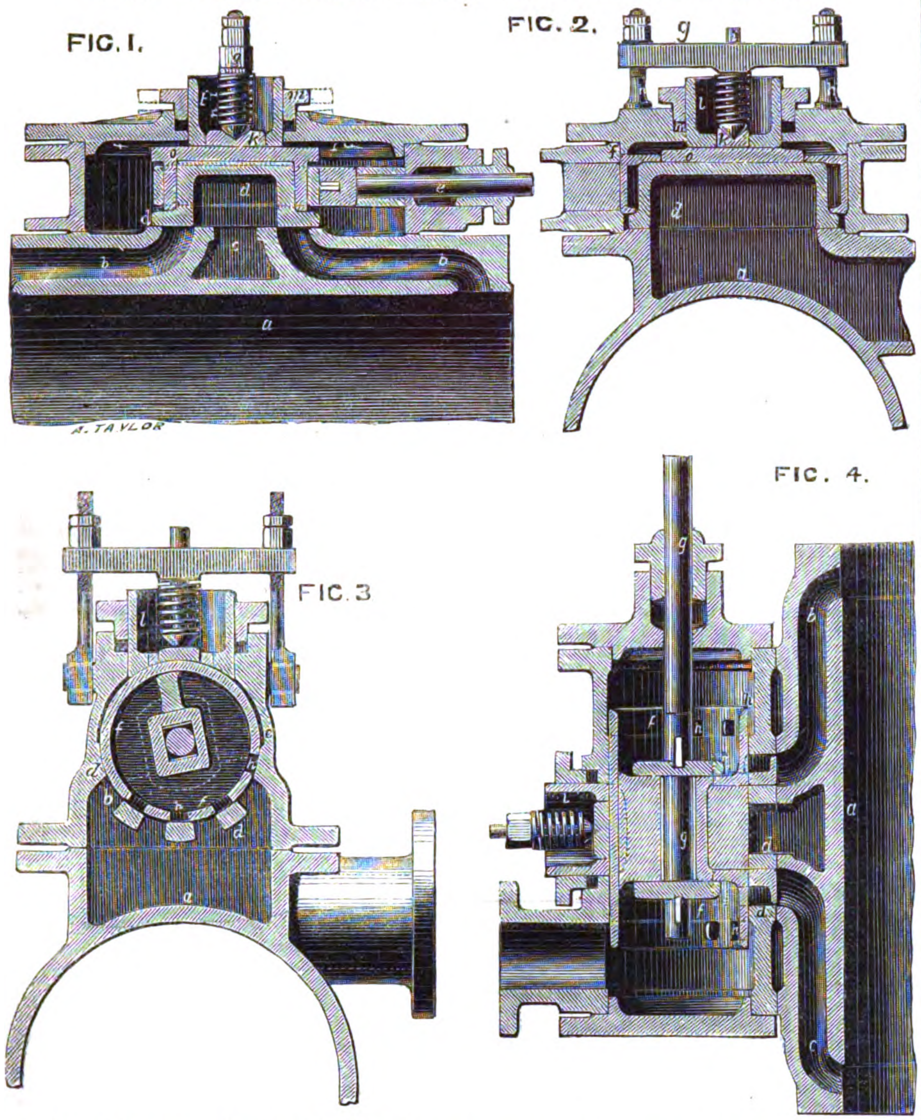
purpose of traversing the bearing carriage D. Any other means may be used for the purpose of traversing the bearing carriage instead of the hydraulic cylinder, as convenient. When a tyre, hoop, or ring is to be rolled or operated upon in the machine the action is thus:—The upper roll is raised, the bearing carriage is then traversed back from the lower roll, so as to leave the intermediate space between the end of the roll and the frame open and free for the passage of the bloom or tyre into or between the rolls, the bloom or tyre is then introduced, the bearing carriage is then traversed back to the roll; the upper roll is then brought down, and the rolling proceeds in the usual manner of such operations. This being finished, the upper roll is again raised sufficiently, the bearing carriage is traversed back, and the tyre, hoop, or ring removed from the machine. When hoops or rings of greater width than the interval of space between the end of the lower roll and the frame above referred to are required, the machine is so constructed that the lower roll itself is traversed longitudinally to any extent requisite to allow the passing of the hoops or rings into and from between the rolls. The end A^{11} of the lower roll is supported by the bearings, E, F, upon the sliding carriage G which is traversed by the hydraulic cylinder H, thus the lower roll is traversed, as required, for the introduction and the withdrawal of the article under operation in the machine.

DEFRIES' LAMPS.

The following improvements in street lamps have been recently patented by Mr. C. Defries, of Houndsditch.

This invention principally regards those lamps termed street lamps, and its object is to obtain a better light for passengers than is obtainable from street lamps as at present constructed. Further, the proposed lamp will be less costly in its original manufacture, and of very trifling expense in repairs. In the City of London, and elsewhere, it has become the practice to furnish each lamp with a regulator, and this is placed within the lamp under the burner. From the bulk of this regulator, and the opacity of the framing or sashes of the lamp, the light from the burner is greatly obstructed. The inventor proposes to form a lamp of a top and bottom (or upper and lower) frame, connected in the centre by a pipe which runs from the top of the lamp-post (being secured thereto); on the top of this pipe are radii or arms supporting both the lower frame at its top and the upper frame which rests on the said top. The frame in which the glasses of the lower part of the lamp rest is supported on the capital of the lamp-post by scroll work. On the capital of the lamp-post is placed the regulator, and as this is usually of less diameter than the said capital, and the burners are to be considerably above it, no light will be intercepted thereby. Small branches for the burners are let into the pipe which, as aforesaid, passes through the centre of the lamp. The inventor makes channels or grooves, in which are received the upper and lower edges of as many strips or pieces of glass as the formation of the lamp may render desirable; these he places in the channels so as to form top, sides, and bottom. The centre pipe is either made a reflector, or coated with any material. The top of the lamp rests on the bottom part, and is to be lifted therefrom when lighting, or it may be hinged to the framing, and turned back for that purpose. A lamp is thus produced without any framing or sash bars between the top and bottom of the lower part or body of the lamp, all being glass, with the ex-

PETRIE'S IMPROVEMENTS IN SLIDE VALVES FOR STEAM-ENGINES.



ception of the narrow framing (which holds the glass) immediately above the regulator or stop-cock, no hindrance is given to the light. In case of breakage of any of the glass, it is only necessary to take out the pieces with the fingers, and in the same way insert a new strip or piece, which drops at once into position, no putty or other fixing being required, and the glass having room for expansion or contraction consequent upon atmospheric changes.

PETRIE'S IMPROVEMENTS IN SLIDE VALVES FOR STEAM-ENGINES.

The following invention for improvements in slide valves has been recently patented by Mr. T. Petrie, of Rochdale, Lancashire.

The invention consists, firstly, in a method of removing steam pressure from slide valves, for which purpose the inventor opens a portion of their back surfaces to the atmosphere, or upon the same principle places such back surfaces in communication with the condenser or similar apparatus. In the accompanying drawing this part of the invention is shown by figs. 1 and 2. A portion of the cylinder is at *a*, the ports at *b*, and the exhaust passage at *c*. The slide valve, of ordinary construction, is shown at *d*, worked by means of the rod *e* in the usual manner. At the front of the valve box *f* there is a cross bar *g*, mounted upon screw studs *h*, and carrying loosely a pin *i*, which abuts at its inward end againsta cross piece *k*, carried by a hollow piston *l*. This piston passes through the face of the valve-box, and through a stuffing-box *m* formed thereon. Between the cross bar *g* and a shoulder upon the pin *i* is a spring *n*, which therefore tends to force the said pin forward and with it the piston *l*, until its inward end presses against a plate *o*, attached to and moving with the slide valve *d*. The plate *o* in the direction of the slide valve's motion is of such a length, that during the opening and closing of the ports the inside aperture of the piston *l* will always be closed, and an escape of steam from the valve-box thus prevented. It will be seen that as the piston is open to the atmosphere, it represents a given surface upon the slide valve from which the steam pressure is removed, and that this removal may be increased or diminished as desired by varying the area of the said piston. In order to secure at all times a sufficient pressure to keep the slide valve to its seat, the spring *n* is employed, and its elastic force may be regulated by tightening or loosening the nuts of the cross bar *g*.

The next part of this invention is shown at figs. 3 and 4, in which a portion of the cylinder is at *a*, and the ports at *b*, *c*. The valve seat is at *d*, and instead of being flat as for ordinary slide valves, it is a portion of a cylinder formed in the valve-box *e*. The slide valve is at *f*, cylindrical in form, so as to fit the seat *d*, and it receives the usual sliding motion by means of the rod *g*. Each of the ports *b*, *c*, consists of several (in this instance, four) separate passages, and there is a corresponding number of passages *h* formed in the cylinder, constituting the slide valve. Supposing the passages *h* (fig. 3) to be situate opposite to those shown at *b* (and which constitute a port) be coincident, then the upward and downward motion will alternately open and close the ports as in ordinary slide valves; but if during this reciprocating motion a turning of the rod *g* be effected, then the passages *h* will be brought opposite to the solid parts of the seat, as seen in fig. 3, and the steam will be shut off. This turning of the shaft may be effected by any ordinary mechanism connected to a moving part of the engine, and adapted to suit different constructions of engines or situations, or it may be caused to take place sooner or later through the medium of the governor, as is well understood in applying cut-off motions. The apertures *h* in the slide valve for the port *c* are situate between those which belong to the port *b*, so as to obtain the necessary alternate action.

In the drawing is shown the first part of the invention combined with that just described, excepting that in this instance the piston *l* is formed at its inward part so as to correspond to the curve of the cylindrical slide valve.

PAY OF ENGINEER OFFICERS WHEN IN CHARGE OF ENGINES.

The following circular has been issued by the Admiralty:—

Admiralty, June 18, 1863.

With reference to the regulations at present governing the rates of pay of engineers in charge of engines, under which engineers and assistant engineers in charge are granted one shilling per diem extra, no allowance being payable to chief engineers or to engineers for special charge: My Lords Commissioners of the Admiralty are pleased to direct, by the authority of Her Majesty's Order in Council, dated the 11th inst., that the following rates of extra allowances shall in future be paid to engineers of every grade, when in charge of engines of ships in commission, in lieu of those at present established:—

	Rate per day. s.	d.
When in charge of engines under 200-horse power	1	0
When in charge of engines of 200-horse power, and under 400-horse power	1	6
When in charge of engines of 400-horse power and under 700-horse power	2	0
When in charge of engines of 700-horse power and upwards	3	0

Engineers and assistant engineers, in charge of engines of ships not in commission, to receive as at present 1s. per diem.

By command of their Lordships,
C. Paget.

ON THE FINANCIAL ENCOURAGEMENT BY GUARANTEES OF COLONIAL AND FOREIGN RAILWAYS.

Mr. Bidder, in taking part in a discussion on a Paper on the Scinde Railway, read at the Institution of Civil Engineers, by Mr. John Brunton, M.I.C.E., spoke as follows:—

Looking, on the one hand, at the vast extent of India, and its prodigious population, and on the other, at the very few effective ports, and comparing it with Great Britain, with only a fifth of the population, but with ports on every part of the coast, the importance of the question was at once evident; in fact, he believed that no outlay, however large, would be misapplied which went towards perfecting the ports of India. Mr. Brooks had correctly stated that the only two good ports were Bombay and Kurrachee; Madras was no port at all, and Calcutta was as bad as it could be; yet those were, at present, the only outlets for the vast trade of India.

The question to which he wished to direct attention was far more important than that of the engineering, or of the ports. It was as to the mode in which Indian railways were, in future, to be carried out and worked, and he believed that on that question would depend the future extension and success of railways in India. There was one great satisfaction in looking at the map of India, that the lines at present executed and in progress were in the right direction. The lines from Calcutta and Kurrachee, meeting at Delhi, with their eventual connection at Bombay, must be the permanent backbone of the railway system in that country; and if that system were completed, and if nothing more remained to be done, it would be unnecessary

for him now to advert to the peculiar conditions which attached to the construction of Indian railways, and the difficulties under which they had been carried out. When the railways in India were projected, three financial systems were open for consideration. First, their being carried out by private enterprise—that broke down at once, because the capitalists of England were disinclined to take them up on their own account. Secondly, the method of subvention, which never was, he believed, seriously entertained. Thirdly, there was the system of guarantee, which had been ultimately adopted. Before further adverting to that system, he would remark, with a view to prevent misconstruction of what he was about to say, that he had no strictures to make upon the mode in which it had been administered, whatever imperfections might attach to the system itself. That it had been carried out with any degree of success was, he believed, greatly owing to the endeavours of all parties to make it work. Every one had gone, more or less, beyond strict routine, otherwise the railway system in India must long ago have collapsed. At present, the railways in India were entirely carried out on a system, by which the Government guaranteed a certain rate of interest on the outlay. The result was, that the Government was liable for the interest on all the outlay, so that, in fact, they had to look to the receipts of the railways for the repayment of the liabilities thus incurred. The Government, therefore, felt it necessary to overlook the whole lof this outlay, and for that purpose there was estab ished a system of supervision, permeating into the greatest minutiæ. The consequence was that all individual energy and all independent activity were restrained; and, as he said before, unless the authorities, particularly the official directors, so far as his experience went, had applied themselves very much to the oiling of the machinery, he thought it must very soon have stopped altogether. He trusted, therefore, that his remarks would be taken as applied to the system, and not to individuals, or to bodies of individuals; for he was bound to say that India was a field which brought out, in every respect, and in a most peculiar manner, the energies of the Anglo-Saxon race.

The whole political system of England, from the beginning of the establishment of her rule in India to the present time, had been, theoretically, the worst possible; and that glorious empire had been established by the individual energy of those who represented this country in India. This remark applied peculiarly to those who had been connected with the railways of India. The amount of work which the directors, particularly the chairmen, had gone through, was prodigious; the amount of correspondence was marvellous, and that they should have had the patience to drag through it, was, he was bound to say, perfectly astonishing. The question arose, whether it was desirable that the system should be changed, and whether so much yet remained to be done in India as to make it desirable that the reconsideration of the system of making and working railways in India should be seriously entertained. With regard to the extension of railways in India, the backbone of the system was still far from being completed; the line from Umritsir to Delhi, a length of 300 miles, remained yet to be accomplished. If the Indus had been a deep, quiet canal, the carrying of the railway system along that valley might for some years have been postponed; but the Indus was perhaps the worst specimen of inland navigation that could be conceived, and, as the author had stated, the channels of navigation were 570 miles in length, as against 470 miles of direct route. Mr. Bidder had very carefully considered the question of the Indus flotilla, and he was every day more satisfied, that the necessity of occupying the valley of the Indus with a railway was becoming more urgent. Even in regard, therefore, to that backbone, there was about a thousand miles of railway yet to be constructed. The question then arose as to the best mode in which it could be carried out, and the best system of working it, when completed.

He had already stated that the Government of India was liable for a given rate of interest upon the whole outlay for the railways; there was, therefore, a distinct interest in the receipts, and the same minute supervision was exercised in the working as in the construction of the line. Before any comparatively unimportant step could be taken in the Punjaub, sanction had to be obtained from the Lieutenant-Governor of the Province, which he could not grant without reference to the Governor-General of India; and, in a similar way, the Commissioner of Scinde was powerless without the sanction of the Governor of Bombay. Then again requisitions, for manufactured railway material and for workmen, sanctioned by the officials he had referred to, had to be reviewed, commented upon, and endorsed by the Secretary of State for India in Council in London, before the most urgent want could be supplied. As regarded the construction, he was satisfied that the necessary restrictions which the system imposed caused a waste of time to the extent of 25 per cent., at least an equal waste of money. But in the working, the results would, he believed, be far more serious. How was it possible to work a railway efficiently, economically, and energetically, to develop the traffic, and adequately to meet the ever-varying demands of the public for accommodation, when a new foreman could not be appointed, nor his salary be fixed, without the manager undertaking a large amount of correspondence, involving duplicates and references to perhaps two or more jurisdictions, and a necessary delay of months. Take such a case as the London and North-Western Railway, and he asked could such a system be worked at all, if a correspondence begun in England had to be concluded in Calcutta, and passed through the Government Departments, before practical effect could be given to it. These departments, he fully admitted, were most anxious to do what was right and proper—desirous even to go out of their way to give facilities; but still that channel must be gone through, and the result of such a system, whatever its effects might be upon the original construction, would be felt, in his opinion, much more seriously afterwards, in the management and in the traffic arrangement.

To return to what he considered the system ought to be, and on which he spoke with some decision, from the experience he had had of its satisfactory working in another quarter. First, with regard to the construction of the railways, he thought that the Government should receive tenders from companies of capitalists for the completion and equipment of a line of railway, for example, between two given points, for a definite sum of money, and stating the amount of subvention they required from the Government, to be paid in cash, or by an equivalent. The character of the line, as regarded materials, workmanship, and accommodation, being defined, the maximum rates of fares, the regulations connected with the public service, such as conveyance of troops, &c., being fixed, the total capital, the amount of subvention, and the approval of the railway by the Government on the completion of the same, being provided and stipulated for, the construction and the working should be left entirely to the management of the company, who should take, as a first charge upon the nett revenue, interest upon their portion of the capital, up to an agreed amount, say 5 per cent., and the surplus revenue afterwards to be divided in agreed proportions between them and the Government. By so doing, all the energy of independent management would be brought to bear, and that management would work with the same responsibility and limitation as in this country. He believed that upon that system alone, the full advantages of railway communication in India, or in any other country, would be realized.

He would, for the sake of illustration, assume a case, that of a railway up the Indus Valley, 500 miles in length, and that the reasonable cost, including equipment, was £10,000 per mile, or that a capital of £5,000,000 would be required. Of this he would suppose the Government to furnish £5,000 per mile, or two and a half millions of capital, either in cash, or by an equivalent guarantee; and as the company would have to find the balance, and to satisfy the Government that the bargain had been efficiently carried out, there would be every possible responsibility thrown upon the executive, that all the money would be economically and judiciously applied. Then the working, subject to conditions with the Government similar to those he had indicated, should be conducted entirely by the company, who should rely upon the receipts of the railway alone for a percentage upon their capital up to, say, 5 per cent.; and, after that, the nett receipts should be divided, say two-thirds to the Government, and one-third to the company, as an inducement to the latter still farther to develop the traffic, and to work economically. This arrangement, of course, implied a proper audit of accounts for the satisfaction of the Government. He believed that it would be to the advantage of Government to apply this system of working to railways already opened for traffic, and to those now under construction; for instance, the lines from Kurrachee to Delhi, a length of from 600 to 700 miles, exclusive of the Indus Valley. For the privilege of working these lines, Government might receive, by tender, a contribution from a company of say three or three and a half millions sterling, which would be more than adequate for the subvention of the Indus Valley line, which, if carried out, would complete a system of 1,100 miles, or thereabouts, from Kurrachee to Delhi, with a preferential capital of about five and a half millions sterling, with a preferential interest of 5 per cent., and a further contingent advantage from surplus nett receipts. He was certain that the Government would get more profit under that system than under the present one, of taking the whole of the profits to meet the liabilities they had incurred, and they would have that contribution to apply to the extensions which might be made to this great backbone of railways throughout India; because though it was a poor country, mile for mile, yet when it was considered that there was one mile of railway in England for every 5,000 inhabitants, as against one mile of railway in India for every 50,000 inhabitants, it would at once be seen that, in India, the necessity for branches and extensions would grow in importance every year.

Looking to the rapid rate of increase of the trade of India, exhibited by the growth of the traffic on the Scinde Railway, in the face of the greatest possible hinderances to the transit of goods from the interior, he had the strongest possible conviction, that the application of individual skill and energy would realize a fair return upon all the capital which might be contributed, either by Government or by private capitalists, and concurrently, incalculable advantages would result to the trade of India generally.

He did not think it was necessary to enlarge his observations on this subject. He had pointed out what occurred to him as the rational system to adopt, a system which, he believed, might be made to work very practically. It was the system on which the Norwegian Trunk Railway was carried out. Parties in England contributed one-half the capital, and the Government the other half. The English contractors took 5 per cent. preference, and the Norwegian Government took 4 per cent., and the surplus was equally divided. That system had been carried out without any difficulty or contention whatever. He did not mean to say that those exact terms would apply to India; but a system which admitted of independent energy, and obviated the necessity of state interference in construction, and a restriction in all the arrangements by which alone railways could be effectually carried out, would, in his opinion, be found advantageous to that great empire, and economical to the Government.

TO CORRESPONDENTS.

M. E. (Salford).—The best practice allows a shrinkage of about 3-16ths of an inch, in a 36 in. wheel—that is to say, the tyre should be bored out 1-16th of an inch smaller than the wheel on which it is to be placed. This rule is, however, frequently departed from, much depending on the kind of iron of which the tyre is composed.

G. G.—Dr. Dauglish's patents are dated October 1st, 1856, number of specification, 2293; and August 21st, 1857, number of specification, 2224. We have given abstracts of both the patents.

AMATEUR.—If you have put colza oil on your drilling machine, we are not surprised that you should find it set fast and cut. Take it asunder, clean all the bearings, &c., with turpentine, clean carefully off, and use lard-oil, or sperm in future.

STEAM FIRE-ENGINE TRIALS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—The MECHANICS' MAGAZINE of the 31st ult. contains a notice of the trial of the "Manhattan" American steam fire-engine, at the Shadwell entrance of the London Docks, on the 25th July last, and also an inaccuracy which I must correct.

It is said that the engine threw "a very steady jet through a 1¼ in. nozzle to a distance of 'about' 150 ft." The distance, as measured in my presence

and that of several other engineers, was 189 ft. in the first trial, and 190 ft. at the second. The measurements were made by the men of the London Fire-engine Establishment, and with the time, size of nozzle, pressures, &c., carefully noted by me; and as one or two of the reporters present copied my note, which they had every opportunity of verifying, I am rather puzzled to account for the curious results of this trial which have appeared in the different journals. The engine, I am informed, worked splendidly the evening before.

Your obedient,
Chas. F. T. Young, C.E.

7, Duke-street, Adelphi, August 4, 1863.

[As Mr. Young was present, he must be aware that the jets thrown for a few seconds to the distances he names did not deserve the term "steady," and the jet, although discharged from a nozzle 1¼ in. in diameter, was really ⅛ in. smaller, in consequence of the peculiar construction of the adjutage.—Ed. M. M.]

Miscellanea.

At the monthly meeting of the London Association of Foremen Engineers, held at Swithin's lane, on Saturday, the 1st inst.—Mr. Muir, of Woolwich Arsenal, in the chair—a Paper was read by Mr. Humes, "On the Construction of Locks."—Next week we hope to be able to furnish our readers with a copious report of that gentleman's successful exposition of lock making.

We regret to learn (says the *Levant Herald*) that the Porte has decided on erecting machinery for rolling and bending ships' armour plates. The immense cost of such apparatus, and of its subsequent working, will, we feel confident, speedily demonstrate that the work in question could be far better and more cheaply done in England—whence the machinery is to be brought—than at Yildiz-Kiosk, where the expensive experiment is to be tried. The advice which has counselled this investment is certainly far from sound.

Plumbago has recently been introduced as the basis of a superior cement for steam joints, and the general metallic connections of the engineer. It is composed of 6 parts of plumbago, 3 of slacked lime, 8 of sulphate of baryta, and 3 of boiled linseed oil. This compound, it is said, secures a perfectly air and steam-tight joint, much superior to that obtained by the use of red lead.

Directions have been received at Chatham Dockyard from the Admiralty for the construction of a 12-gun iron vessel, the first of a squadron of iron frigates of a somewhat smaller size than those of the "Warrior" and "Achilles" class, which are to be built from the designs of Mr. Reed, Chief Constructor of the Navy. The new vessel is to be commenced in No. 2 Dock as soon as the "Achilles" is completed, which will be in about three months. She is to be about 80 ft. shorter than the "Achilles," and altogether will, it is anticipated, be a decided improvement on the present large iron steamers.

It is stated that the Russian Government have given a large order to Messrs. Krupp, of Essen, in Prussia, for muzzle-loading guns of the heaviest description, for the purpose of arming the fortress of Cronstadt, and that they have also ordered a considerable number of steel projectiles.

The Alexandra Park Company, it is stated, have definitively arranged with Messrs. Kelk and Lucas for the purchase of the International Exhibition Building, and its re-erection on the ground of the company, according to new designs suited to give full effect to the general objects of the undertaking.

We see that "Bernot's Patent File-cutting Machine Company" have already placed their shares in the market. The project is certainly carried on with a spirit and energy which should secure that success which usually attends companies who have, as in this case, a good foundation on which to work.

There was launched on Saturday last, from the yard of Messrs. Palmer Brothers and Co., at Howden, a beautifully-modelled screw steamer named the "Royal Standard." She is the property of Messrs. Wilson and Chambers, of Liverpool, and is the first screw steamer built for the White Star line of Australian packets, for which trade this noble vessel is intended. The "Royal Standard" has three decks. She is 225 ft. long, 40 ft. beam, 27½ ft. deep; her measurement is 2,000 tons, and the height between decks is 7½ ft. clear. The engines are to be of 140-horse power nominal, and are constructed on the high-pressure surface-condensing principle. They are of the inverted direct-acting description, with cylinders 45 in. in diameter, and 42 in. stroke, supplied with steam of 60 lb. pressure from three cylindrical boilers.

The prospectus has been issued of the British and Foreign India-Rubber Company, with works at Nottingham, and in France and Belgium, for the purpose of carrying on and developing the manufacture of india rubber generally, on a much more extensive scale than has hitherto been attempted. The capital is fixed at £200,000, with a first issue of one-half of that amount. The application of india rubber to submarine telegraphy forms a very important feature in the plans of the company. This material was stated, in the report of the Government Commission on Telegraphs, to far exceed any other substance in its valuable properties as an insulator, and the directors state that they have every reason to believe, that on the plans they propose they will be able to adapt it to the purpose required, in a manner which has not hitherto been effected.

It is announced that an Anglo-French company is formed to provide the amount necessary for the construction of a gigantic balloon on a system invented by a M. Nadar, capable of raising 80 persons in a car two storeys high, which will contain provisions and other necessaries, including, it is said a printing press. The diameter of the balloon is to be equal to three-fourths the height of the towers of Notre Dame. 12,000 yards of white silk have been supplied by a Lyons manufacturer, at 7f. the yard. This monster balloon is to be inaugurated next month at the races of Baden-Baden. Subscribers for the trip have already set down their names. It is to last eight days and eight nights. After having made a trip across the Channel and another in the Mediterranean, the company at whose expense the balloon is to be constructed will exhibit it in London, Paris, and New York. The produce of the exhibitions is to be employed in the construction of a definitive aerial locomotive.

A new iron vessel, expressly built for the conveyance of petroleum, was launched on Saturday at Newcastle. The ship has, properly speaking, no hold, but a series of iron tanks extended from deck to keel. In contradistinction to the principle often necessarily adopted in many vessels built to suit particular carrying trades, neither the necessity of economizing space nor the nature of the intended cargoes have necessitated the builders of the "Atlantic" to depart from the most exact rules of taste in marine architecture; and the result is that, viewed from every point, the greatest elegance is visible in the design of their ship. Her length over all is 145 ft.; breadth of beam, 28¼ ft.; and depth, 16 ft. 9 in. The launch was extremely successful.

A correspondent of the *Colliery Guardian* states that, at the Blackleyhurst Collieries, near St. Helen's, Lancashire, worked by Samuel Stock, Esq., on the property of Sir Robert T. Gerard, Bart., on the 11th inst., in a downbrow in the Little Delf Mine, at a depth of about three hundred yards from the surface, a spring of oil was met with, which continued to flow with great force for some time from the floor of the mine, but has now nearly ceased. Steps, however, are being taken to prove whether any quantity of the oil exists in the strata or not. The colour is of brown amber, has little or no smell, what little there is seems to resemble linseed oil. This is considered very peculiar, as mineral oils generally smell very strong. It is of a highly lubricating nature, burns freely, and there is no doubt that if it exists in any quantity it will prove a valuable source of wealth.

The paddle-wheel steamer "Salamis," 250-horse power, which, according to rumours current at Chatham within the last few days, is intended to be fitted as a yacht for his Royal Highness the Prince of Wales, was taken out of Chatham harbour on Friday for the purpose of making her first trial of speed on the completion of the fitting of her engines. The engines were in charge of Mr. Ravenhill, of the firm of Ravenhill, Salkeld, and Co., by whom they have been manufactured, and the trial was watched on the part of the Admiralty by Mr. Baker, chief engineer, Mr. Lang, master shipwright, under whose superintendence the "Salamis" was built at Chatham Dockyard, and other officials belonging to the establishment. The vessel was in charge of Mr. Blakey, second master, Queen's pilot at Chatham. With 180 tons of coals on board, the "Salamis" drew 9 ft. 11 in. aft and 9 ft. 6 in. forward; or, in other words, she was on a nearly even keel. She is fitted with Morgan's patent feathering floats, and her engines are fitted with all the modern improvements. The diameter of the cylinders is 61 in., and the length of stroke 4 ft. 6 in. She has four boilers in which the steam is generated, and 10 furnaces, in addition to which she is fitted with superheated steam apparatus. The vessel was taken considerably past the Mouse Light, as far as the entrance to the Downs, when, with full boiler power, the speed of the vessel was very satisfactory. Two runs were made at the measured mile, Maplin Sands, at about three-quarter speed, and, notwithstanding that the paddle-wheels were only making an average of 34 revolutions per minute, the vessel attained an average speed of close upon 15 knots per hour. With an improved trim, and with 38 revolutions of the paddle-wheels, there is little doubt that she will attain an average of 16 knots per hour, which is exceedingly satisfactory. During the trial her engines worked with remarkable smoothness, and, notwithstanding that it was the first occasion of their being tried, there was no priming and no occasion to stop the machinery on account of hot bearings.

We learn from the *Times*, that Captain H. Broadhead, commanding the Steam Reserve at Portsmouth, and Mr. George Murdock, inspector of machinery afloat at the same port, have forwarded to the Admiralty for inspection the models, drawings, and specifications of a breech-loading gun and gun-carriage, the joint invention of the two officers, intended to supply the want of a heavy smooth-bore gun. The gun is bored throughout from muzzle to breech, the circumference at the latter end being slightly increased. The breech is closed by a screw-plug, which closes the breech effectually by a quarter turn after the plug has been slid into its position. The carriage on which the gun is mounted appears, however, to be of the most immediate importance. The difficulty experienced in working and training the 95 cwt. 68-pounders on the main decks of our iron ships during a cruise was found to be most serious, and it was acknowledged that some other mode of working and training such guns than by the bungling, slow, handspike method must be adopted to render the ships' maindeck guns efficient. To meet this difficulty the present carriage has been constructed. Two-cranked shafts are fixed underneath the carriage, with the apex in front on a cup-bearing resting on the deck, the rear ends of the cranks carrying metal trucks on wheels. By a side lever and rope-fall the gun and carriage can either be thrown on the cup-bearing and rear trucks, and thus become a pivot broadside gun, or it can become an ordinary broadside gun, by lifting with the lever the cup-bearing and rear trucks. As a pivot broadside gun, two men on each side of a 10-ton gun with a simple rope-fall in their hands can train it with the utmost rapidity and nicety, and without a handspike being at all brought into play.

A new pilot lifeboat, 23 ft. in length, built by the shipwright department of Woolwich Dockyard by order of the Board of Admiralty, from designs furnished by Mr. Turner, the master shipwright of the yard, was forwarded to Devonport by the steam storeship "Fox," on Wednesday. The boat, which is self-righting, cannot sink by reason of the buoyancy effected by air-cases and open tubes through the bottom. If turned over and filled with water it will right itself in about fifteen seconds. The air cases are moveable, so as to be easily taken out for painting and inspection, with the exception of the long middle trunk, through which the open tubes pass, and which is fastened to the boat for the purpose of strengthening her lengthways. Should any water penetrate into the trunk through any unforeseen mishap, it can be cleared out readily by the removal of some metal screws in the lower part of the sides of the trunk. But should the boat by any possibility ship a sea, filling her entirely, it would run out in fifteen seconds. If a small quantity of water should find its way into the joints of the cases they can be emptied by taking up the short piece of midship bottom board and the case under each side. The sailing qualities of the lifeboat were tested at various times in the river preparatory to her being despatched from Woolwich yard. On one occasion during a high wind, when all her sails were set, she continued her course buoyantly with her gunwale 12 in. under water. The boat is ordered to undergo an additional course of sea trials at Devonport for the information of the Lords of the Admiralty.

The *New York Herald* says:—The "Monitor" torpedo consists of a monster shell, 30 ft. long, weighing upwards of 6,000 lb., with a charge of 700 lb. of powder. By means of a raft—the "devil"—these shells are pushed some fifty feet ahead of the "Monitor," suspended at any desirable depth. We shall know in good time how the rebels succeed in ob-

structing the passage of the "Monitors" when armed with these terrible shells, the explosion of which will resemble an earthquake under water. It appears that the naval officers were afraid of employing the potent means placed at their disposal for clearing Charleston harbour of obstructions, for fear the explosion of the shells would act backwards on their vessels. As might be supposed, the constructor has guarded against such an occurrence. The Secretary of the Navy, with a view of removing all doubts on this point, ordered a trial to be made last winter with one of the rafts, the very "devil" afterwards towed to Port Royal. The trial proved eminently satisfactory; for although the shell pushed up a mountain of water 50 ft. high above the surface of the Hudson, near the head of the raft, not the slightest injury was sustained by the latter. The perfect preservation of slender pieces of wood attached under the raft, proved beyond a doubt that the effect of the explosion was, as had been designed, in the forward direction only. This singular feature of the "Monitor" torpedo we are not at liberty to describe. What we have stated on the subject can do no harm, as it is known at Richmond as well as at Washington. So also is the fact that a couple of shiploads of these under-water pioneers are now at hand where their good services are most needed. We therefore acquit Mr. Welles on the charge of want of enterprize as regards the torpedoes. But is it not time to order Admiral Dahlgren to put steam on the "Monitors" and push the torpedoes past Sumter up against those rebel obstructions?

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 3471, 3482, 3, 6, 23, 38.
Boilers and Furnaces—*none.*
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 3473, 3482, 3486, 25.
Ships and Boats, including their fittings, 35.
Cultivation of the Soil, including agricultural implements and machines, 21.
Food and Beverages, including apparatus for preparing food for men and animals—*none.*
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 3476, 3481, 3483, 3484, 3489, 1, 4, 8, 16, 19, 27, 33, 34, 36.
Buildings and Building Materials, 28.
Lighting, Heating, and Ventilating, 3471, 3487, 3499, 7, 10, 13, 26, 31.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 3467, 3474, 3488, 11, 14, 17, 24, 29.
Metals, including apparatus for their manufacture, 3472, 3475, 9, 20, 22, 32, 37.
Chemistry and Photography—*none.*
Electrical Apparatus—*none.*
Warfare, 3469, 3478, 3485, 2, 18, 30.
Letter-Press Printing—*none*
Miscellaneous, 3468, 3470, 5, 12, 15.

3467. C. E. Wilson. *Improvements in articles of wearing apparel for the neck.* Dated December 29, 1862.

This invention applies to collars and scarfs, and consists in attaching to the front part of the bands of collars one or two bands of any material suitable for scarfs, which bands hang down, take the position of, and appear like an ordinary scarf; a stud or pin, or both, may be used to secure the article on the neck of the wearer. *Patent abandoned.*

3468. W. E. Newton. *Improvements in preserving organic substances from decay.* (A communication.) Dated December 29, 1862.

This invention consists in treating fresh skins with the heavy oil of tar, or other suitable hydro-carbon. *Patent completed.*

3469. W. Billinghurst and J. Requa. *An improved portable battery.* Dated December 29, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3470. J. Johnston. *An improved surface refrigerator.* Dated December 30, 1862.

This invention consists of an apparatus for cooling brewers' and distillers' worts and other liquids effectually and speedily without pipes or other appliances which prevent thorough cleanliness. It comprises a series of shallow troughs of cast iron or other material placed side by side, with a communication formed at each alternate end to admit of the water flowing continuously through the whole series. These troughs are formed with circular or rectangular studs or projections cast on the bottom, and on these are placed thin sheets of twined copper with indentations or sinkings on the upper surface thereof, formed at an angle of about 45 degs., with the sides in the direction of the flow of the liquor or wort which passes over them. The sides, ends, and divisions may be of cast iron, wood, or other material fastened to the water troughs, and securing the copper sheeting thereto. The liquor exposed to the action of the atmosphere flows over the copper plates, and the water flows beneath them in a contrary direction. The indentations in the surface of the copper-plates agitate the wort or heated liquid in its flow, thereby causing ripples, breaking up the stream at each indentation, and materially accelerating the cooling process by continually exposing a fresh combination of liquid to the action of the atmosphere and the cooling plates. The studs or projections in the bottom of the water troughs also break up the volume of water, and support the cooling plates, against the under surface of which at close intervals different particles of water are brought into contact in consequence of the obstruction presented by the studs. The wort or liquor to be cooled is admitted at one end of the refrigerator, and flows over the various channels to the outlet at the other extremity. The water flows in an opposite direction under a certain head or pressure to ensure positive contact with the cooling plates. The flow of water can be so regulated that the outlet it can be of about the same temperature as the liquor which enters at the same end. *Patent completed.*

3471. J. Robson, jun. *Improvements in ornamental fittings for domestic stove grates.* Dated December 30, 1862.

In carrying out this invention, the inventor takes ordinary coke, cinders, charcoal, coal, the refuse of furnaces, brick burrs, stones, or wood, or similar forms to coke or cinders, made of Paris plaster, or plastic substances, or stamped out of sheet metal, and gives them an electro-conducting surface, by rubbing them over with plumbago, or by dipping them into a solution of bisulphuret of carbon, and then into a weak solution of nitrate of silver and water. He then coats them by electro deposition with any of the ordinary metallic deposits, such, for example, as copper, and then connects the coke or other material herein described with an electric battery, and places the same in a deposition trough containing sulphate or other solution of copper, until the said coke or other material is coated with copper. He then removes the said materials, and dips them into ordinary acid pickle, and afterwards washes the same in water, and dries them in sawdust, or in any other ordinary manner, and lacquers or varnishes them for use; or he would sometimes coat the said coke or other materials with gold size, or other ordinary adhesive substance, and cover their surfaces with gold or bronze leaf, foil, or dust, parts of which he would sometimes burnish and varnish, when they would be ready for use to be filled into the grates required to be ornamented. *Patent abandoned.*

3472. J. H. Johnson. *Improvements in ingot moulds employed in the casting of steel and other metals.* (A communication.) Dated December 30, 1862.

This invention relates to a peculiar construction and arrangement of moulds to be employed in casting ingots of steel or other metals, and consists in making such moulds syphon-shaped, the metal being first poured into a main compartment, which communicates at its lower end only with one or more other compartments by a lateral aperture or apertures, the metal rising in such other compartments slowly and steadily, although poured rapidly into the main or filling compartment. Each of the compartments in connection with the main compartment is closed at the top with the exception of a small aperture for the escape of the air and gases. Any number of these compartments may be combined together in one apparatus, which is composed of several parts held together by bolts and keys, or otherwise, so as to be readily separated for the purpose of opening the several moulds when the ingots are to be removed. *Patent completed.*

3473. H. A. Bonneville. *Improvements in the manufacture of saddles.* (A communication.) Dated December 30, 1862.

This invention consists in an improved apparatus which offers the advantage of being able to employ the same saddle for horses of different sizes. This apparatus may be applied to all saddles, whatever may be the mode of construction of the saddle-tree, as well as to pack-saddles of other beasts of burden placed before and behind. The changes to be made in the apparatus, in order to adapt it to the above purposes, are to unite the stays in a different way by a double hinge, in cases where these parts are placed edgeways, or by a single hinge when they are placed flat. *Patent completed.*

3474. F. B. Anderson. *Improvements in watches and other timekeepers.* Dated December 30, 1862.

This invention consists in constructing those parts of watches and other time-keepers known as hollow fusees and as stops to prevent the main-spring from being overwound, as hereafter described. The patentee forms a disc on the arbor, by preference in a piece with it, and sinks a recess in the outside of the fusee brass, into which the disc is fitted and secured by soldering or other attachment. He forms a square on the back of the arbor, to receive what he terms a gatherer or stop, which works inside a steel split ring, formed with three or more teeth, and with an abutment on the inside thereof. As the watch is wound, the gatherer takes round a tooth at every complete revolution, until the spring is wound up, when the gatherer comes in contact with the abutment, and prevents overwinding. The split ring is encased in a box fastened on to the back of the pillar plate. *Patent completed.*

3475. W. and H. Bowser. *Improvements in coating and protecting iron or steel with another metal.* Dated December 30, 1862.

The arrangements for carrying out this invention comprise a reverberatory furnace for heating the iron or steel, and a chamber in close communication therewith, to which latter the iron or steel is transferred to have the coating metal applied to it. Arrangements may be made for working continuously; in other words, for gradually moving the articles through the furnace and coating chamber at a rate which can be adjusted to suit the heating powers of the furnace, and the size of the articles under treatment, and so that, whilst some are undergoing the latter part of their treatment, fresh articles may be entering and passing through the furnace. The iron or steel plate, sheet, or other like article to be coated, having had its surfaces rendered as clean as possible, must be heated to about a welding heat, or to such a heat that the copper or other coating metal will melt freely upon its surface. When sufficiently heated, the article is transferred to the coating chamber, wherein there is brought into contact with it the coating metal, in the form of sheets, strips, or grains, proportioned to suit the thickness of coating to be applied in one operation. When these operations are performed in a careful and skilful manner, the coating metal becomes most intimately and firmly united to the iron or steel article, and it spreads over and covers the edges and all exposed parts of the article, the combination being so complete, that the article may be subsequently re-heated, rolled, hammered, or drawn without the coating metal becoming separated. *Patent completed.*

3476. W. Mould. *Certain improvements in machinery or apparatus for plaiting or folding and measuring fabrics.* Dated December 30, 1862.

This invention consists in having two swinging concave blades or knives placed above a reciprocating table in the form of a segment of a circle, such table being supported in a suitable framework, and allowed to yield or fall, the yielding being obtained by means of a vertical rod, to which the yielding segmented table is attached, such rod sliding through the axis of the segment, and supported by means of a strong elastic material passing around the axis of the segment, and underneath a transverse section; fixed to the lower end of such vertical supporter rod, on each side of the segmented table, is a roller covered with india rubber, flannel, or other suitable material, and which may, if required, be actuated and caused to revolve in one direction by means of the cloth being forced beneath it, and retained in such position, during such repetition of the folding blades, by means of a ratchet wheel upon its end coming in contact with a pawl or catch. *Patent completed.*

3478. W. Richards. *Improvements in cannon and other firearms, and in apparatus connected therewith.* Dated December 30, 1862.

According to one portion of this invention, in constructing breech-loading cannon in which the bore is continued through the breech end of the piece, and the charge is introduced from behind, the patentee closes the breech for firing with a stopper fitting into the bore, and behind the stopper the sides or walls of the gun are cut through, so that a block or fitting piece may be introduced transversely across the bore, so as to support the stopper and prevent its being driven out at the back. The stopper has a rod or stem attached to it with a handle at the back, and the filling piece is slotted to allow this rod or stem to pass. After firing, in order again to load, the block or filling piece is raised until the bore is left clear, and then the stopper is drawn out at the back by hand; another projectile or cartridge is then introduced, the stopper is replaced, and the block or filling piece again lowered behind it. Lever apparatus is employed in order to raise the block or filling piece. *Patent completed.*

3479. W. Clark. *Improvements in governing apparatus.* (A communication.) Dated December 30, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3480. C. Beslay. *Improvements in steam-engines.* Dated December 30, 1862.

The object of this invention is to entirely obviate the condensation or formation of liquid in the interior of the cylinder, and even to make the cylinder a means of superheating the steam, instead of detracting from its effect as heretofore. For this purpose, the inventor envelopes the steam cylinder with a jacket somewhat as in ordinary, having a space of one or two inches between the jacket and the cylinder; this may also be the case with the bottom and cover. These spaces he puts in communication by means of two pipes, with an air chamber or chambers placed in the chimney or passages leading therefrom, and subject to the action of the heat and flame passing through the furnace. He disposes a fan or screw exhauster in a chamber, through which one of the tubes of communication passes, which, being driven, keeps up a constant circulation of air through the cylinder jacket, and returning thence to the air-heating chamber, to be again returned to the cylinder jacket, and so on. *Patent abandoned.*

3481. R. Bottomley. *Improvements in machinery for twisting and doubling yarns or threads of cotton and other fibrous materials.* Dated December 31, 1862.

This invention consists in placing the mechanism for pinching or holding the threads next to the first guide eyes for the threads, then the cushion or "list board," then the hooks or water trough, then another cushion or list board, and lastly the plummet rail; thus it will be seen that the position of the plummet rail and pinching or holding apparatus is reversed, and by this means the patentee obtains the drag of the cushions or list boards, guide eyes, and plummets, in combination with that of the pinching or holding apparatus for holding the threads when "winding-on." *Patent completed.*

3482. W. B. Adams. *Improvements in railways and tramways.* Dated December 31, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3483. F. Applegate. *Improvements in the manufacture of a kind of woollen cloth, known to the trade as doeskin.* Dated December 31, 1862.

This consists in the use of two kinds of weft, of the same shade of colour or dye, but of different commercial values, the one being dyed woaded or indigo colour, which is used

only for the face of the cloth, and the other a common or unwoaded colour which is used for the back of the cloth. *Patent completed.*

3484. J. S. Smith and J. Hardman. *Certain improvements in power looms for weaving.* Dated December 31, 1862.

This invention relates to that portion of the power loom known as the stopping or knocking-off motion employed to stop the further action of looms when the shuttle does not complete its race from box to box. The improvements consist in an arrangement of mechanism which is designed to release the knocking-off handle, and thereby transfer the snap from the fast to the loose pulley, and simultaneously to put a break upon the fly-wheel, which machinery may be thus described:—At a convenient place on the framing of the loom, beneath the stop rod finger, a rod is secured, upon which is a sliding piece carrying a rod to act upon the handle; this sliding piece is also connected by means of a wire or rod to a bell crank lever, one end of which may be brought into contact with the fly-wheel (as a break) upon the other end being acted upon or struck by a tappet secured in a catch box on the end of the tappet shaft which extends beyond the framing; thus if the shuttle does not enter the box, the stop rod finger strikes the sliding piece and releases the knocking-off handle, the sliding piece also draws the wire, which places the lever in a position to be struck and pressed by the extra tappet on the end of the tappet shaft, by which means a break is put on the fly-wheel and the stoppage of the loom is readily effected. *Patent abandoned.*

3485. J. W. P. Field. *Improvements in breech-loading firearms.* Dated December 31, 1862.

This invention has for its object the diminution of metal in the joint piece, so as to admit of its being inserted in the wood, and the gun thereby made in the form of an ordinary "bar" or front action lock gun. For this purpose, instead of employing a bolt with a circular motion, as usual, for closing the joint, the patentee adapts and applies a slotted bolt with a rectilinear motion to the pivot of the lever, such bolt being projected into a notch to close the joint by means of a cam or cams formed or fixed on the said pivot of the lever. The extent of movement of the bolt is limited by the length of the slot therein, and of the operating part of the cam or cams, and there is or may be a spring in the box in which the bolt is contained, which has a constant tendency to press the bolt into the notch. By the use of this form of bolt the width of the metallic joint piece is reduced, so as merely to form a guide on each side of the bolt. *Patent completed.*

3486. W. Clark. *Improvements in the arrangement of the parts of railway trains, and in the application of power for their propulsion.* (A communication.) Dated December 31, 1862.

This invention is based on the employment of several sets of driving wheels, which are individually rigid, but connected together so as to form a flexible train. Their number depends on the power of adhesion desired, or on the radius of the curves of the railroad, or the weight disposed on each wheel. *Patent abandoned.*

3487. J. M. Napier. *Improvements in heating apparatus.* Dated December 31, 1862.

This invention may be termed a water stove, and is peculiarly adapted for heating apartments where a regular and moderate warmth is required. The inventor employs a vessel of convenient form, and of dimensions suited to the apartment to be heated. This vessel contains water, which is heated by the application of gas jets to a portion of its exterior; and in order to increase the heating surface and economize the gas, he allows the heated products of combustion to pass through tubes or other passages placed in the body of the containing vessel before being conducted away from the stove into the chimney of the apartment, or otherwise into the outer atmosphere. When the water becomes heated, the heat passes off through the containing vessel, and is communicated to the air of the apartment. The surface of the stove which is in contact with the air should be of such extent that the water need not be raised to the boiling point in order to heat the apartment sufficiently. *Patent abandoned.*

3488. F. Jaques. *Improvements in cases for pipes, mouthpieces, cigars, and other analogous articles.* Dated December 31, 1862.

These cases are made either of wood, hard leather, papier maché, hard rubber compound, or other suitable material, the cases being provided with an elastic or spring joint, which will have the effect of closing the parts and keeping them closed without other appliances. This spring joint the inventor prefers to make of vulcanized india rubber; and in carrying out the invention, the case should be made in two parts, of some hard substance which will be sufficiently rigid to prevent the article contained therein from being broken. *Patent abandoned.*

3489. F. Lobet. *A new system of constructing double weft forks, applicable to every description of power looms.* Dated December 31, 1862.

The object of this invention is to construct and adapt to power looms an apparatus which shall have the effect of stopping the loom whenever the weft breaks, or the shuttle by any accident shall not enter its box properly. To this end, forks consisting of two, three, or more prongs, are deposited between the batten or slay between each end of the reed and the shuttle boxes. These forks are mounted on a spindle or shaft, so that they may vibrate thereon, and project slightly across the shuttle race. Spiral or other metal springs are adapted to the spindle or shaft for the purpose of drawing it, and the forks mounted thereon, round in one direction when the batten is driven forward. These spiral or metal springs tend to lift up the forks; but another set of springs is adapted to a stationary part of the loom, and is made to pull round the spindle or shaft and the forks in the opposite direction when the batten is drawn back. Another set of vibrating forks is mounted on a second spindle or shaft, the prongs of this second set of forks being so arranged that they will, when required, enter the spaces between the prongs of the first set of forks. Upon the fork spindles or shafts are mounted levers or arms which are connected in any convenient manner to the stop motion of the loom. *Patent completed.*

3490. W. Maltby. *Improved means of extinguishing fires by the use of substances not hitherto supplied.* Dated December 31, 1862.

In carrying out this invention, the inventor dissolves bisulphate of ammonia in about seven times its own weight of water. This solution he sprinkles or discharges in small jets over any burning mass, which has the effect of immediately arresting the flames, and quickly stopping the combustion. Although he prefers, and claims, the use of this solution of bisulphate of ammonia alone for this purpose, yet, in some cases, he finds it advantageous to use any soluble silicate, either combined with the latter or free. *Patent abandoned.*

---

1. R. H. Collyer. *Improvements in the method of, an apparatus for, preparing materials for the manufacture of paper and similar purposes, part of the invention being also applicable to other operations in which materials are subject to the action of hot agents.* Dated January 1, 1863.

For the purposes of this invention, the patentee subjects the materials to showers of hot water and showers of alkaline liquor used alternately, and to superheated steam—that is to say, he heats the materials at intervals with showers of hot water, and at the same time acts on the materials with superheated steam, and between the showers of water he heats the materials with showers of alkaline solution or liquor, still continuing to inject superheated steam. Instead of superheated steam, as above, he sometimes uses hot air, or superheated steam and hot air together. *Patent completed.*

2. W. H. Brown. *Improvements in battery plates.* Dated January 1, 1863.

Hitherto battery plates have been made of malleable iron affixed to the sides of vessels of war without being hardened. Battery plates so made have proved insufficient to resist the flat-headed hardened shot and shell fired from the Whitworth gun. Now the present inventor proposes to harden one side or face of such battery plates to the depth of about one-fifth of their thickness, leaving the remaining four-fifths in a mild or ductile state to support the hardened part. *Patent abandoned.*

3. G. Allcroft. *Improvements in pressure gauges and vacuum gauges.* Dated January 1, 1863.

This invention consists of a circular case fitted with a dial and pointer of the ordinary kind. The pinion of the pivot on which the pointer is fixed is actuated by a toothed quadrant working on a suitable fulcrum, and there is a helical spring fixed to the tail of the aforesaid quadrant, and to a pin in the case for keeping the pointer steady. To the bottom of the case of the gauge a piece of metal is affixed, in which is fitted a corrugated steel plate of the ordinary kind, protected from corrosion by india rubber. At or near the centre of the aforesaid corrugated spring, and in contact therewith, the short curved end of a horizontal lever is adjusted upon a fulcrum pin, and to the long end of the said lever a short rod is connected by a pin, the upper end of the said short rod being connected to a slotted lever which may be adjusted to the toothed quadrant before mentioned by a set screw. The inventor proposes, in constructing pressure or vaccum gauges intended to be used in locomotive engines, to adapt a syphon or curved thermometer within the case of the gauge visible from the outside thereof. *Patent abandoned.*

4. M. E. Boura and A. E. Francis. *Improvements in the manufacture of elastic fabrics.* Dated January 1, 1863.

This invention has for its object the production of an elastic fabric or material consisting of a combination of fabrics with any suitable gums in an unvulcanized state, the whole so heated and combined in the process of manufacture that when finished the said fabric or materials shall possess elasticity. *Patent completed.*

5. J. T. Smith. *Improvements in obtaining motive power from steam and the products of combustion.* Dated January 1, 1863.

This invention consists in the following arrangements for obtaining power:—The inventor places a furnace or furnaces in the interior of a boiler, and supplies it or them with air by an air compressing pump or machine. He passes the whole of the heated air and other products of combustion from the furnace into the water in the boiler. The steam, hot air, gases, and other products are afterwards passed through a filter or tube, and are employed in a high-pressure engine; the cylinders of the engine are, by preference, lined with steel, or are made of chilled or case-hardened iron. In some cases he causes the feed water to pass through the fire bars which are made hollow for the purpose. *Patent abnadoned.*

6. R. Faulds. *Improvements in traction engines, or common road locomotives.* Dated January 1, 1863.

This invention has principally for its object the propelling and steering or manoeuvring of tracton engines in a more efficient manner than has hitherto been attained. The invention consists mainly in applying the propelling power (which may be obtained by steam-engine details arranged in any convenient way) to two or more pairs of wheels, whereby the necessary bite of the ground will be obtained without excessive weight and other inconvenience, whilst the ascending of inclined roads, or the drawing of extra loads, will thereby be greatly facilitated. *Patent abandoned.*

7. J. J. Southgate. *Improved arrangements for portable fire-escapes.* Dated January 1, 1863.

In carrying out this invention, the patentee provides loose trousers or a vest, or a complete suit of trousers and vest, or a bag or sack, made of strong canvas, or other strong and pliable material; or he substitutes for these what may be considered by most persons a more desirable thing, viz., a strong belt of leather or canvas provided with tongue and buckle or other adjusting fastener, he securely attaches thereto the lower end or ends of elastic or spring cords, and the other end or ends of such elastic or spring cords he secures to a ring, hook, or staple, so constructed that it may be readily secured to the wall or place, or to an article contained in the apartment in close proximity to the window, or other point of egress, so that the garment or garments, or the belt before mentioned, may, in case of fire, be applied without delay to the person of any one seeking to escape, who may upon casting off from the window or other place descend in a gradual manner, by reason that the whole weight of the body being suspended by the said elastic cords, the amount of the elastic power of the said combined cords being regulated by the average weight of what are known as heavy persons. People of less weight being brought down by the same means with the assistance of the hauling rope. The person using this escape is enabled to regulate to some extent his position by using his hands and legs, so as to keep out of the reach of flames issuing from the building, the same being, however, more amply provided against by means of the hauling rope or cord worked by any person or persons on the pavement or ground below. *Patent completed.*

8. J. Jones. *Improvements in finishing or stiffening textile fabrics.* Dated January 1, 1863.

According to this invention, the roller employed to apply the size, starch, or stiffening fluid to a suitable fabric is caused to move in opposition to the fabric, which in passing the roller comes in contact with a small core of the surface of the roller, by which the fabric receives the size, starch, or stiffening fluid from the surface of the roller, and is thereby stiffened without requiring the use of the ordinary pressing roller or cylinder with its back cloth and appurtenances. *Patent completed.*

9. W. Souter. *Certain apparatus for raising and planishing metals.* Dated January 1, 1863.

We cannot here give space to the voluminous details of this invention. *Patent completed.*

10. W. Robinson. *An improvement or improvements in glasses for lamps used in ships, railway carriages, and for other like purposes.* Dated January 1, 1863.

This invention consists in moulding or otherwise forming these glasses, which are usually of a globular or hemispherical form, with raised ribs or flanges on the outside surface; these ribs or flanges may be in any suitable form or design, and by their production from the surface they preserve such surface from being scratched in placing the glasses in their positions, whilst at the same time a brilliant light and ornamental appearance are also ensured. *Patent completed.*

11. J. E. Baker and J. Landon. *Improvements in the construction of boots, shoes, and other coverings for the feet.* Dated January 1, 1863.

An extension of time for filing the final specification of this invention having been petitioned for, the documents relating to the invention cannot at present be seen.

12. W. A. Distin. *Improvements in pipes for smoking tobacco and other herbaceous compounds.* Dated January 2, 1863.

This invention relates to certain improvements upon a former invention, for which letters patent were granted to the present patentee, dated January 3, 1856, No. 18, for the invention of "Improvements in pipes for smoking;" and the present improvements consist in an improved mode of connecting the tube of the pipe to the bowl thereof, for which purpose the said tube and bowl are formed as follows:—The upper end of the bowl (which may be of any suitable substance or material) has a shallow recess formed therein with annular grooves, the said grooves communicating by a passage formed along and in the substance of the side of the bowl, with a reservoir at the bottom thereof for the passage of oil from the tobacco or other herb. Into the said recess a flange piece fits, the said flange piece being fixed around the lower part of the tube or stem of the pipe. A part of the said tube extends beyond and below the said flange piece, and such extended part fits into the upper end of the bowl of the pipe, after the smoking herb has been placed therein, to a level with one or more small holes made through the said bowl for lighting the contents thereof, and for admitting air thereto. There is a hole (or holes) formed in the side of this part of the stem or tube corresponding with the hole or holes through the side of the bowl, as before described, so that when it is required to light the pipe, or put it out, the same may be done by the smoker holding the bowl of the pipe with one hand, and turning the tube or stem partly round with the other hand, stop pins being adapted to the flange piece of the tube and bowl to ensure the proper opening and closing of the orifices in the bowl; or the same result may be obtained by constructing the tube or stem to lift up and push down. There is a hole formed across the tube of the pipe just above the flange piece before stated. A dome-shaped piece of thin metal fits air-tight around the aforesaid tube or stem and the upper part of the bowl of the pipe, and forms a chamber for the smoke which passes from the bottom of the bowl up a channel in the side of the said bowl, as in the bowl described in the specification of the aforesaid former patent, thence the smoke passes by the cross hole up the hole in the tube or stem to the mouth of the smoker. *Patent completed.*

13. F. C. Bakewell. *Improvements in apparatus f[...] burning oils and other inflammable fluids as fuel.* (A c[...]munication.) Dated January 2, 1863.

This invention consists in the employment of oil or [...] inflammable fluids of less specific gravity than w[...] fuel, for the purposes of heating, cooking, ge[...] steam, &c., by burning it without any wick or o[...] vehicle as it floats on the surface of a body of wate[...] which it is passed to supply the consumption ca[...] combustion. *Patent completed.*

14. C. Eyland. *An improvement or im[...] the manufacture of buckles.* Dated January 2[...]

This invention consists in making the [...] [...] used for vest backs and other simil[...] [...]forming the rim and centre b[...]

solid from one piece of metal, afterwards bending the chape and the point piece round the solid centre bar, thus making the buckle a double-acting one, with the chape capable of being turned either way. *Patent abandoned.*

15. H. Lyon. *Improvements in the finish and mode of packing cigars, and in apparatus used for these purposes.* Dated January 2, 1863.

This invention consists in ribbing cigars lengthwise or crosswise, or the ribs may run in both directions, forming the surface into squares. This finish is made at the same time the cigars are pressed into the required shape, the result being obtained by means of a fluted or ribbed board placed at the top and bottom of every layer of cigars. It is proposed to make up these ribbed cigars in the ordinary manner, but the improved mode and apparatus for packing are especially designed and adapted to cigars with the common finish. The apparatus used consists of a simple block containing as many holes as there are to be cigars in a bundle, the said holes being of such a size as to admit the ends of the cigars and conveniently arranged in circles. *Patent abandoned.*

16. A. Bamford, R. Blomley, R. Taylor, and J. Lett. *Improvements in looms for weaving.* Dated January 6, 1863.

This invention is not described apart from the drawings. *Patent completed.*

17. E. T. Hughes. *Improvements in producing designs upon velvets, cloth, furniture hangings, and similar materials.* (A communication.) Dated January 2, 1863.

In the manufacture of velvets, cloth, furniture hangings, and other fabrics, to produce raised, friezed, or tufted designs thereon, the inventor employs a warp of silk, cotton, hemp, flax, or other similar material, with a long weft of wool, and he is thereby enabled to produce various designs on the fabrics. To produce raised, friezed, or tufted designs on woollen fabrics, he uses woollen threads well twisted, which work close, and woollen threads not twisted so much, by which he obtains the desired effect. These friezed or tufted designs can be applied to all fabrics, such as carpets, velvet, furniture hangings, and materials for various other purposes. *Patent abandoned.*

18. W. H. Muntz. *An improved method of attaching sheathing to iron or other vessels.* Dated January 2, 1862.

This invention consists in attaching the sheets of india-rubber, or other insulating or "anti-galvanic" material, to the vessel's side, and the metal sheathing to the insulating material, by means of marine glue, or such other cement or adhesive substance as will resist the action of sea water, instead of nailing or riveting the same, as previously practised or proposed. *Patent completed.*

19. H. J. Sergeant. *Certain improvements in the method of dressing and finishing silk fabrics, and fabrics composed of silk, cotton, and wool.* Dated January 2, 1863.

This invention consists in the novel application, employment, and use of glazed paper as a surface to effect the dressing or finishing of the silk when wound upon a beam together prepared or otherwise. The silk is treated, as is customary, with a solution of gum or gelatine, and partially dried by means of fire or steam chests; it is then to be wound or rolled upon a beam, upon which the surface of paper is also wound in a continuous length, being supplied from another roller; thus the silk becomes enclosed within the surfaces of the paper, and pressure is given by giving tension to the paper. When the beam is full, it may be removed to a drying oven until thoroughly dried, or the paper may be made hot by subjecting it to heat before it is wound on with silk, and thus the silk becomes hot-pressed, dressed, and finished. *Patent completed.*

20. J. E. Dawson. *Improvements in the manufacture of wrought-metal piles, columns, and shafts.* Dated January 2, 1863.

For the purposes of this invention, in forming sheets of metal, each edge of a plate is rolled or formed with an interior flange or rib, and by preference of such exterior form at the butting edges, that when the edges of two plates butt together, the joint between them shall not be a plain or straight line. On the contrary, one butting face is made hollow, undulating, or concave, whilst the other is made undulating or convex, to fit the hollow, undulating, or concave face of the neighbouring plate, though this is not essential, as plain or flat butting surfaces may be formed to the flanges. A series of longitudinal plates, such as above described, are used in producing a pile, column, or shaft. The outside surfaces of the plates may be convex or otherwise, according to the external form intended to be given to a pile, column, or shaft composed of a number of such shafts. The plates forming a pile, column, or shaft are bound together by metal bands fixed externally, which may be shrunk on, or they may be welded on; or they may be otherwise fixed tightly round in any suitable manner, so as to hold the series of butting plates of which a pile, column, or shaft is composed securely together; or the plates of which a pile, column, or shaft is composed may be combined or held together in any other convenient manner. *Patent completed.*

21. R. C. Ransome. *Improvements in reaping machines.* (A communication.) Dated January 2, 1863.

For the purposes of this invention, in order to deliver the cut crop at the side of the machines in quantities suitable to be tied up into bundles, a single rake is used, which is mounted at the end of an arm which moves on a suitable axis. The lower ends of the rake teeth, when delivering the cut crop, come close to and are moved over the platform of the machine. The arm with its rake performs or reciprocates to and fro in the segment of a circle of about 90 deg. The platform of the machine is formed of a segment of a circle, the cut crop is received on to the front end of the platform where the cutters are situated, and the cut crop is delivered at the other end of the platform, which comes to the side of the machine. The outer edges of the platform are raised. The arm of the rake receives its reciprocating motion primarily from the rotary motion of the running wheel or wheels, from which the cutters also derive their motion in an ordinary manner. The rake in its return stroke, after delivering a quantity of the cut crop, is, as before stated, caused to rise and pass back over the platform, so that the teeth are well above the platform, and are also above the further quantity of the cut crop thereon. The requisite motions to the arm of the rake are by preference imparted to it by means of a crank pin or eccentric, or suitable cam, which gives motion to a connecting rod, which at its other end moves on a rocking lever or links. The connecting rod, by a lever mounted on an axis carried by the connecting rod, gives motion to the axis of the arm of the rake, and causes it to move in the arc of a circle, for which purpose one end of such axis of the arm is arranged to move or turn about an axis, whilst the arm of the rake is also made to perform a partial rotation by the outer end of the lever (the axis of which is carried by the connecting rod) being connected or attached to an arm or projection at the other end of the axis of the arm. And all the necessary motions to the rake are thus arranged to be given without any sudden or injurious changes of motion, but on the contrary all the motions are easy and steady. *Patent completed.*

22. A. S. Bolton. *Improvements in the manufacture of wire.* Dated January 2, 1863.

This invention consists in manufacturing wire in manner hereafter described—that is to say, the patentee takes a tube, pipe, or cylinder of copper, or copper alloy, and places therein a core or rod of solid copper or copper alloy, and he manufactures wire by rolling and drawing the same, or by both rolling and drawing the same to the size required. Or, he takes a core or rod of copper or copper alloy, and encloses it in two or more tubes, pipes, or cylinders of copper or copper alloy, and manufactures it into wire as before described, and that at one or more operations. *Patent completed.*

23. H. Jones. *Certain improvements in steam engines.* Dated January 3, 1863.

This invention relates to those descriptions of steam engines wherein the waste steam is not condensed; for instance, as in locomotive or traction engines, where it is used to increase the draught of the furnace, and the invention is designed to regulate the amount of such draught. The first part of the invention consists in regulating the amount of air caused by the waste steam, by lengthening or shortening the "blast pipe" through which the steam passes, for which purpose the upper part of the pipe is made to slide on the lower, and arranged with rack and pinion, or otherwise, so as to be raised or lowered by the engine-driver as required, the draught being decreased as the aperture of the "blast pipe" approaches the top of the funnel or smoke outlet, and increased as it is lowered therefrom. A second part of the invention consists in connecting the axle boxes of traction engines together by a bar embracing or connecting all the axle boxes on one side of the engine together, and those on the opposite side by a second bar so as to distribute or equalize the strain thereon. *Patent abandoned.*

24. E. Skull and E. Mealing. *Improvements in chairs and other seats or apparatus for sitting or reclining on, which improvements are also applicable to tables.* Dated January 3, 1863.

The object of these improvements is so to arrange the parts of chairs and other apparatus for sitting or reclining upon (as well as of tables) that when not in use or for the purpose of transit they may be readily folded in a compact form. For this purpose the legs on each side are hinged or turn upon centres affixed to the seat or surface for sitting or reclining upon, and they then, when the seat is in position for use, cross one another, and at the point of crossing a pin or stud in the one passes through and rests upon one end of a slot in the other. When the seat or other surface is required to be packed for transit, the seat or other surface will be folded between the legs, when the studs in one leg on each side will slide in the slots of the other, and all the parts will be flat. In the case of chairs or other seats with backs, one end of each side of the back is connected to corresponding legs by pin joints, whilst other pins pass into slots provided for them in such sides of the back. In like manner may elbows or other rests be similarly applied with corresponding pins and slots. The surfaces of tables may be connected in like manner to the legs to facilitate their folding. *Patent completed.*

25. W. Philippi. *Improvements in the manufacture of bearings and axle boxes for machinery, carriages, and railway rolling stock.* Dated January 3, 1863.

In carrying out this invention the patentee cuts or hollows out the bearing (as show in the drawings), into which spaces he presses the hereinafter described mixture. He cuts up into small pieces 10 lb. of paper, and adds to it 6 lb. of linseed oil. He well mixes and stirs up the two, and sprinkles thereon a mixture of 3 lb. of graphite, and 3 lb. of gypsum, and presses the whole into a homogeneous mass, and places so much of the material produced in the hollowing of the bearing as is necessary to fill the same under a pressure of three atmospheres. In order to give it the proper form, he makes use of a turned iron cylinder, having the form of the axis which is to work in the bearing. When the pressure is given, he places the bearing for 24 hours in a temperature of about 150 deg. Reaumur. *Patent completed.*

26. S. White. *Improvements in the method of and apparatus for purifying, bleaching, and refining oils, and oily and fatty matters.* Dated January 3, 1863.

This invention consists—as regards the method of purifying, bleaching, and refining oils, and oily and fatty substances—in introducing the oil or oily or fatty matters together with a reagent calculated to eliminate or separate the impurities contained in them into a vessel having small orifices or perforations in its sides, and revolving rapidly within a larger vessel, which is open to the atmospheric air, so that when the smaller vessel revolves, the oil or oily or fatty matter combined with the reagent which is used with it for the purpose of purification will be projected through the orifices in the sides of the smaller vessel in thin streams, which will be driven against the internal sides of the larger vessel, and thereby be scattered and subdivided, and will thus be presented, in a partially atomic state, or in a dewy form, to contact with the light and the atmospheric air, by which exposure of the oil or fatty or oily matters in a minutely subdivided state the light, and particularly the oxygen of the atmosphere, produces an improved purification of such oil or fatty matter. The invention cannot be fully described without reference to the drawings. *Patent completed.*

27. W. Astrop. *Improvements in the manufacture of paper.* Dated January 3, 1863.

This invention consists in the employment of fibrous portions of the roots of parsnips, carrots, and turnips, of all kinds, and of the roots, stems, and stalks of the beet, mangold wurtzell, chicory, and rhubarb plants; also of the fibre of the cocoa nut and leaves of the orange plant and flags or reeds; also horse and cattle manure for the manufacture of "half stuff" and pulp to be used in the production of paper and cardboard, the substances and materials hereinbefore enumerated being employed either separately or in any combination with each other, or with any of the ordinary pulps now used in the manufacture of paper and cardboard. *Patent completed.*

28. C. B. Clough. *Improvements in apparatus for curing smoky chimneys.* Dated January 3, 1863.

This invention relates to a peculiar construction and arrangement of chimney top, and consists in adapting to the outside of any ordinary earthenware or other chimney pot a covering of zinc, or other suitable metal or material, surrounding such pot, and leaving an annular space between the pot and the outer casing which should extend to the top of the pot. At the base of the casing, and on diametrically opposite sides thereof, the patentee forms two vertical apertures, and he devides the annular space by placing partitions in the space between the pot and the casing midway between the openings. The wind entering one of these opening is prevented from escaping through the opposite opening by the partitions above-mentioned, and consequently, an upward current of air is carried outside the pot on the windward side of the chimney. Two openings and partitions will be found to answer, but in some cases three or more openings with partitions between them may be employed so as to catch the wind from every quarter. *Patent completed.*

29. W. T. Smallware and C. B. Weaver. *Certain improvements in treating or covering strip steel or other suitable material for the making of crinoline skirts and other similar purposes for which the same may be applicable, and which same treatment and covering may be used for trimming and strengthening certain parts of ladies' dresses.* Dated January 3, 1863.

The object of this invention is to cover strips of steel, or other suitable material for crinolines, in such a way as —1, to provide the means (by forming a selvage) for sewing such covered material to the material or fabric of the skirt to which it is to be attached, the covering being effected in any suitable material or variety of colour, and may be done with great dispatch so as to ensure harmony; 2, to disguise the effect of the hoop-like appearance in crinoline skirts by weaving or producing in the loom at the time of covering the material or otherwise an additional broad flounce, frill, or other ornamental border to extend down below the covered steel, or other suitable material that may be used; 3, in enclosing two or more strips of steel or other material, the same being placed at suitable distances apart, the intermediate space being occupied with a woven fabric of any material or colour, so as to form what is technically called a "fulling," and which may be made with an outer selvage on both edges or frill, flounce, or other ornamental border, on one or both edges as preferred. *Patent abandoned.*

30. W. E. Newton. *An improved method of firing or discharging cannon and other firearms, a part of which invention is applicable generally to the firing of charges of powder.* (A communication.) Dated January 3, 1863.

The patentee claims—1, the combining with the barrel of the cannon or other firearm an insulated plug and extending through the metal from the bore to the outside, such insulating plug to be used with a cartridge having a fusee provided with two conducting wires, so that when inserted in the bore, one will be in contact with the bore, and the other will be in contact with the insulated plug set forth. 2, He claims as an improvement in fusees for igniting powder by electricity the connection of two conducting wires by a feeble or film-like conductor, whether such interposed feeble or film-like conductor be placed direct lyin contact with the powder or with a combustible substance interposed, as described. *Patent completed.*

31. E. B. Keeling. *An improvement in lighting halls, theatres, and other buildings.* Dated January 5, 1863.

This invention is intended to be applied to the lighting of halls, theatres, and other buildings, and relates to the diffusion of intense light, and to the prevention of shadows. The patentee takes an electric light, a lime light, or other source of intense light, and places it in some elevated spot above the space to be lighted. Under or before, or part under and part before this light, he suspends or fits a plain white, tinted, or coloured curtain or screen, and again in some instances he places under or before, or part under and part before, a ceiling of glass or other transparent medium. By these means he removes the obstacles that have hitherto prevented the successful application of the electric, lime, or other intense lights to the lighting of the interior of large rooms and public edifices, and that also have all but confined these sources of light to the position of mere scientific curiosities. It is well known that the chief obstacles have been the intense brilliancy of the lights, their unpleasant white or ghastly hue, and the dense black shadows thrown by them. The first, however, gives so far a margin that the medium of the curtain absolutely utilizes the objection by the sacrifice of brilliancy, but by the complete diffusion of the rays. The second obstacle is overcome by the tint or colour of the curtain or screen giving

any hue most desirable to assimilate with any of the lights now usually employed, whether it be that of gas, of any description of oil lamp, of that of any wax or other candles. The relative use of the curtain or screen to the source of light is the same as that of the clouds to the sun. *Patent completed.*

32. H. Yates. *Improvements in machinery used in the manufacture of shovels and spades, and for raising and shaping metals for other purposes.* Dated January 5, 1863.

This machinery consists, essentially, of a pair of dies having the figure of the shovel or spade or other articles to be shaped. The inventor makes the upper die of the said pair upon a joint on an upright connected to the lower die, the said upper die being capable of being raised from the lower die to the required distance by turning on the said joint. That end of the upper die furthest from the joint has a handle or rod connected to it, by means of which handle or rod the upper die can be raised or brought down upon the lower die. To facilitate the raising of the upper die he connects a balance weight to it near the joint, the said balance weight enabling the workman to raise the upper die with little difficulty. The said balance weight also assists in giving the required momentum to the upper die when it is brought down upon the lower one by the workman. *Patent abandoned.*

33. J. A. Cooper. *The application of a fibre obtained from a certain plant as a substitute or to be used with silk, cotton, flax, and such like materials, which fibre has not been hitherto applied to any of those purposes, and for certain methods of preparing the same for such purposes.* Dated January 5, 1863.

This invention consists in using the fibre which is found immediately under the bark of the plant called the periwinkle as a substitute for, and using the said fibre in combination with, silk, cotton, flax, and such like materials, the same, when properly prepared, being spun into thread and woven into textile fabrics. *Patent abandoned.*

34. J. Howard and J. Bullough. *Improvements in warping or beaming machines.* Dated January 5, 1863.

This invention is not fully described apart from the drawings. *Patent completed.*

35. H. Blacktin. *Improvements in apparatus for saving or preserving money, papers, or other valuable property at sea in case of shipwreck.* (A communication.) Dated January 5, 1863.

This invention consists of a waterproof vessel constructed in the form of a boat, or any other convenient form and size, and of suitable materials, so as to be capable of floating and resisting the action of water and rocks or other bodies. One or two openings or hatchways are made in the top of the vessel, to which covers or lids are to be fixed by screws, bolts, locks, or other suitable means, and whereby they are capable of being made water-tight; money, papers, or other valuable property may then be enclosed in this vessel, and the vessel conveniently placed on shipboard, and which, in case of shipwreck, may be thrown overboard, when it will float ashore, where it may be picked up and the contents be thus saved or preserved. *Patent abandoned.*

36. A. Monnet. *Improvements in twisting and throwing silk and other fibres.* Dated January 5, 1863.

For the purpose of twisting silk and other fibres, three, four, or other number of fibres are drawn off from bobbins on which they have been previously wound, and are caused to pass down under a pulley of glass or earthenware contained in a reservoir of water, the fibres thus moistened pass up over another guide or pulley, and then pass to the twisting apparatus. The twisting apparatus consists of a spindle caused to rotate rapidly by means of a driving band moving in contact with a whirl upon it. The spindle receives at its upper end a circle or ring of metal, which receives and winds up the fibres as they are twisted. This circle or ring is concentric with the spindle, and revolves with it. Within the circle or ring there is gearing or wheelwork actuated by the spindle, and giving motion to a guide through which the fibres pass to be wound on the circle or ring. This guide the gearing causes to travel slowly around the circle or ring, so as to wind thereon the fibre which it carries. For throwing together two or more strands of twisted fibres, the circles or rings with the fibres wound upon them, as already described, are placed on axes, and the strands are drawn from them and passed as in the twisting operation under a pulley contained in the reservoir of water; the strands are then taken over other guides which place them side by side, and they then descend to twisting or throwing apparatus arranged as already described, but revolving in the opposite direction, so that the throwing apparatus whilst laying the strands together takes off more or less of the twist previously put upon the strands. *Patent abandoned.*

37. H. Bessemer. *Improvements in the construction and mode of apparatus to be employed in pressing, moulding, shaping, embossing, crushing, shearing, and cutting metallic and other substances.* Dated January 5, 1863.

The patentee claims—1, Transmitting to the rams of hydraulic presses a self-acting and continuous reciprocating motion through a limited and regulated distance. 2, Transmitting to the rams of hydraulic presses during a portion or near the end of each stroke or pulsation of the rams the force stored or accumulated in a heavy revolving flywheel during the inoperative portion of the stroke of such rams. 3, The method or methods described of regulating the distance apart of the cutting or pressing surfaces or dies employed in hydraulic presses having a continuous reciprocating motion. 4, The employment of a sliding frame in hydraulic presses for the purpose of transmitting the force of the ram in a downward direction on to the article or matter under operation. 5, The employment in hydraulic presses of two pistons acting simultaneously on one cross-head or pressing frame, as described. 6, The employment of two or more rams in one hydraulic press frame, such rams acting independently or simultaneously, as described. 7, The employment of one-armed hydraulic presses in the moulding, shaping, shearing, and pressing of metallic and other substances. 8, The employment of a table or support, with or without rollers, as described, when used in combination with a hydraulic press employed in pressing, shaping, "cogging," or forging ingots, blooms, or other masses of malleable iron or steel. 9, The continuous working of a plunger or force pump not furnished with valves and communicating with such presses. 10, The apparatus described for crushing ore and mineral or other substances. *Patent completed.*

38. H. Chamberlain. *Improvements in generating and condensing steam and evaporating liquids, and in the apparatus employed therein.* Dated January 5, 1863.

In generating steam, according to this invention, the patentee causes a fine spray of hot water, mingled with a small proportion of steam, to be directed between the convolutions of one or more coils of hot-water pipes contained within the generator, such hot-water pipes being connected to coils of similar hot-water pipes contained in a suitable heating chamber or furnace, and give out their heat to the spray and convert it wholly into steam. The steam is collected in a steam chest or chamber inside the generator, and passes off by a steam pipe for use in the ordinary manner. A constant circulation of water is maintained through the heating coils in the generator, and in the heating chamber or furnace by the aid of a centrifugal pump or other water-forcing apparatus. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated March 19, 1863.

737. H. O. Haughton, merchant. Improvements in machinery for drying and cooling grain and seeds. (A communication.)

Dated April 21, 1863.

992. H., E., and S. Yeadon, Stockport, and J. Yeadon, Leeds, reedmakers. Improved healds for weaving.

Dated June 11, 1863.

1455. C. L. V. Tenac, Tredegar, South Wales, civil engineer. A new or improved daily balance book with moveable or sliding tickets or slips. (A communication.)

Dated June 22, 1863.

1561. J. Sainty, Burnham Market, Norfolk, agricultural implement manufacturer. An improved turnip cutter for cutting the last slice.

1563. A. Twaddell, Glasgow, manufacturer. Improvements in sizing or preparing warps.

1597. L. A. Majolier, Stoke Newington, merchant. Improvements in apparatus for carburetting gases. (A communication.)

1769. W. Clark, 53, Chancery-lane, engineer. Improvements in apparatus for charging air or gases with combustible vapours. (A communication.)

1571. W. L. and T. Winans, Dover-street, gentlemen. Improvements in adapting propellers for propelling ocean steam vessels.

1573. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in printing machinery. (A communication.)

Dated June 23, 1863.

1575. J. Murray, Glasgow, engineer. Improvements in machinery for making chains or chain cables and rings.

1577. J. Ellison and A. Rogerson, mechanics, Bury. Improvements in slubbing, intermediate and roving frames, in throstles and winding machines used for the manufacture of cotton or other fibrous materials.

1579. S. Robinson, mechanic, J. Priestley and J. Foulds, overlookers, Bradford, York. Improvements in looms for weaving.

1581. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in breech-loading arms. (A communication.)

1583. W. L. and T. Winans, Dover-street, gentlemen. Improvements in lessening the friction of the rubbing surfaces of the slide-valves of engines and of the journals of shafts.

1585. E. Brooks, Birmingham, manufacturer. Improvemenes in breech-loading firearms.

1587. F. Feichtinger, 26, Cumberland-street South, Belgravia. Improvements in the manufacture of paper applicable for hemorrhoidal complaints.

Dated June 24, 1863.

1589. S. Knowles, calico printer, and R. Hayward, machine engraver, Tottington Mill, near Bury, Lancashire. Improvements in machinery for plaiting and measuring woven fabrics.

1595. T. Skinner, Sheffield, electro-plater and engraver. Improvements in the ornamentation of silver, German silver, Britannia metal, electro-plated, or other plated goods.

Dated June 25, 1863.

1597. R. Ripley, Brook-street, West-square, Lambeth, engineer. Improvements in the method and contruction of a packing, chiefly applicable to piston rods, pumps, and such like, and for forming the joints of gas, steam, or water pipes.

1601. J. O. Mathieu, Paris, gentleman. Improvements in twisting machines, particularly applicable to the manufacture of strings, strands, ropes, or cables.

1607. J. Head and H. Brinsmead, Ipswich. Improvements in machinery applicable to thrashing machines, and for cutting and bruising straw.

Dated June 26, 1863.

1609. W. Clark, 53, Chancery-lane, engineer. Improvements in apparatus for aërating liquids. (A communication.)

1611. W. E. Gedge, 11, Wellington-street, Strand. Improved apparatus for placing tyres on wheels, or hooping or feruling generally, while the metal is hot. (A communication.)

1613. R. Mushet, Coleford, metallurgist. Improvements in the manufacture of iron and steel.

Dated June 27, 1863.

1617. E. T. Hughes, 123, Chancery-lane. Improvements in couplings for hose pipes, and also in connecting axles to the naves or bosses of wheels. (A communication.)

Dated June 29, 1863.

1621. C. Avery, 39, Craven-street, Strand. Improvements in rotary engines.

Dated June 30, 1863.

1623. F. J. Duggan, Bristol, oil and colour merchant. Improved methods of connecting lamp chimneys and other glasses or shades with the burners of lamps.

1627. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in machinery or apparatus for moulding or shaping pottery ware. (A communication.)

1629. C. H. Gardner, West Harding-street, Fetter-lane, lithographic press manufacturer. Improvements in lithographic and zincographic presses.

1631. S. Cole, Moseley, Worcester, manufacturer. Improvements in clasps or fastenings for securing brooches, solitaires, and other dress ornaments.

Dated July 1, 1863.

1633. J. Blake, Accrington, engineer. Improvements in apparatus for reducing and regulating the pressure or quantity of steam, and in discharging the water of condensed steam from cylinders, pipes, and other vessels.

1635. W. Snell, 16, Clement's-inn, Strand. An improved waterproof material. (A communication.)

1637. C. P. Coles, Southsea, captain in the Royal Navy. An improved method of, and apparatus for, working guns in vessels and forts, and discharging them under water.

1639. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in coating or covering metal sheets with metals or alloys, and in the apparatus employed therein. (A communication.)

1641. T. Taylor, Wandsworth. Improvements in railway brakes.

Dated July 2, 1863.

1645. J. J. Shedlock, Vincent-street, Westminster, gas engineer. Improvements in wet gas meters.

1647. A. A. Croll, Coleman-street, engineer. Improvements in the preparation of materials to be used in the purification of gas for illumination.

Dated July 3, 1863.

1652. C. Martin, Brentford, civil engineer. Improvements in the treatment and preparation of materials for the manufacture of paper.

1655. R. Davison, London-street, civil engineer. Improvements in machinery for decorticating and cleaning corn and other grain. (A communication.)

1657. H. Brinsmead, Ipswich. Improvements in cooking apparatus.

1659. H. S. Warner, Trinidad, gentleman. An improved mode of, and apparatus for, treating or preparing megass and other substances to be used as fuel.

Dated July 4, 1863.

1661. J. C. Macdonald, Waddon, near Croydon, and J. Calverley, 26, George-street, Peckham. Improvements in the manufacture and application of printing apparatus.

1662. M. E. Eyth, 60, Boulevard de Strasbourg, Paris, engineer. An improved rotative engine.

1663. J. McDonald, Ashton-under-Lyne, manager. Certain improvements in jacquard looms.

1665. J. Grimson, Leicester, engineer. Improvements in shuttles for weaving narrow fabrics, and in mounting and fitting them to the battens.

1669. A. Norman, Clarendon-road, Notting-hill, gentleman. An improved apparatus for fanning or for agitating air.

1671. G. A. Barrett, W. Exall, C. J. Andrews, and A. Barrett, Reading, engineers, and J. L. Bowhay, Modbury. Improvements in the arrangement and construction of fixed and portable combined thrashing machines.

Dated July 6, 1863.

1674. W. B. Adams, Holly Mount, Hampstead, engineer. Improvements in wheels and their tyres, axles, and axle-boxes.

Dated July 8, 1863.

1696. J. Gibson, 31, Ormond-quay, and S., R., and W. Trulock, Essex-quay, Dublin. Improvements in breech-loading firearms.

1702. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in the construction of locks and fastenings. (A communication.)

Dated July 13, 1863.

1744. H. N. King, 42a, Milsom-street, Bath, photographic artist. An improved mode of, and apparatus for, producing spectral illusions on the stage.

1750. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in sizing or gumming warp and weft threads. (A communication.)

Dated July 15, 1863.

1776. Dr. C. Clemm, Dresden, Germany. New employment of magnesia and its combinations in manufactures.

Dated July 16, 1863.

1780. S. A. Cooper, packing-case maker, 5, Lower Chapman-street, St. George's East. An improved packing case to contain bottled beer, wine, or any other liquid in bottle.

1786. G. Rand, Stoneham, Hants. Improvements in the the means of, and apparatus for, boiling and cooking.

Dated July 17, 1863.

1798. E. Alcan, King-street, City, merchant. An improvement in gas burners. (A communication.)

1800. G. F. Wilson and G. Payne, Sherwood Works, Battersea. Improvements in the manufacture of soap.

Dated June 18, 1863.

1806. J. Murdoch, Portsmouth, Hants. Improvements in the construction of steam and vacuum gauges.

Dated July 20, 1863.

1808. W. Simpson, engineer, and J. Hutton, accountant, Northampton. Improvements in the manufacture of hollow cutting tools.

1810. R. B. Brassey, manufacturer, and J. Hargreaves, manager, Ashton-under-Lyne, Lancashire. Improvements in machinery or apparatus for sizing and drying yarns and fabrics.

1812. J. and W. H. Bailey, Albion Works, Salford, Lancaster, turret clock makers. Improvements in apparatus for the prevention of boiler explosions.

1814. W. H. Gedge, 11, Wellington-street, Strand. Im-

provements applicable to inland navigation. (A communication.)

1816. F. Ayckbourn, Moreton-street, patent bed manufacturer. Improvements in air and water beds, pillows, bolsters, and cushions.

1818. R. Weare, Northwood, Stoke-upon-Trent, merchant. Improvements in water-closets, commodes, slop pails, and other like apparatus or utensils.

Dated July 21, 1863.

1824. C. S. Duncan, Inverness-road, Bayswater. Improvements in the means of, and apparatus for, heating, melting, boiling, evaporating, and other useful purposes.

1826. J. E. Varmer, Coleman-street. Improvements in the manufacture of umbrellas and parasols.

1828. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in watches and other timekeepers. (A communication.)

1830. W. Naylor, Queen's-road, Dalston, engineer. Improvements in safety valves and in apparatus connected therewith.

Dated July 22, 1863.

1832. P. R. Jackson, Rolling Mills, Salford, engineer. Improvements in machinery for rolling hoops and tyres.

1838. I. Perrin, Birmingham, Warwick, engineer. An improved danger signal to be used on rifle, artillery, and other practising grounds.

Dated July 23, 1863.

1844. G. Davies, Serle-street, Lincoln's-inn, civil engineer. An improvement in revolving firearms. (A communication.)

1848. W. Clark, 53, Chancery-lane, engineer. Improvements in saddles. (A communication.)

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated July 23, 1863.

1846. M. Meisel, 14, Park-walk, West Brompton, engineer. An improved apparatus for regulating the speed of trains on railways, and in assisting the locomotive engine and train in ascending and descending inclined planes. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, August 4, 1863.

655. W. J. Clapp and N. Coats. Armour plates.
737. H. O. Haughton. Drying and cooling grain and seeds. (A communication.)
740. C. Webster and W. Forgie. Clearing out the interior of foul chimneys or flues when on fire or otherwise.
743. R. Couchman. Supporting or carrying ladies' parasols.
762. H. Hancock. Making gas.
766. J. Eyles. Cheffonier bedsteads.
769. J. Reilly and W. Martin. Lubricating horizontal shafting and bearings.
781. C. Monson. Gravitation engine.
782. R. Armitage and C. Senior. Stretching fabrics.
787. L. Christofleau. Firearms.
790. M. L. Parnell. Locks.
792. W. Johnson. Pocket-books, purses, wallets, and bill-cases.
802. W. M. Morgan. Coating metals.
803. R. A. Brooman. Scouring wool. (A communication.)
804. J. Taylor, jun. Rain-water pipes.
815. J. Dale and G. Bischof, jun. Manufacture of aniline, napthylamine, and other analogous bodies.
816. J. Musgrave. Steam boilers.
825. J. Smethurst. Steam engines and boilers.
830. R. A. Brooman. Electric telegraph printing apparatus. (A communication.)
832. H. Hamer. Tanning.
838. M. Henry. Lubricating. (A communication.)
846. J. W. Law and J. Inglis. Moulds for casting.
853. A. P. Price. Manufacture, production, and refining of metals.
864. F. C. Bakewell. Wicks for lamps. (A communication.)
865. B. Cooper. Feeding scribbling or carding engines.
881. A. V. Newton. Projectiles. (A communication.)
902. A. V. Newton. An offensive weapon. (A communication.)
904. A. V. Newton. Stirrups. (A communication.)
921. P. P. Raly. Constructing breakwaters, piers, sea-walls, and other similar structures.
1066. J. H. Johnson. Drying and cooling grain. (A communication.)
1071. G. Davies. Agitating and mixing substances. (A communication.)
1095. J. McF. Gray. Riveting, caulking, chipping, and otherwise operating upon and treating metals and other substances.
1242. H. Bennett. Puddling iron.
1350. W. Loeder. Rails for railways. (A communication.)
1424. W. E. Newton. Needles. (A communication.)
1567. L. A. Majolier. Carburetting gases. (A communication.)
1575. J. Murray. Making chains, or chain cable and rings.
1702. W. E. Newton. Locks and fastenings. (A communication.)
1726. R. Hornsby, jun., J. Bognall, and W. Astbury. Traction engines.
1788. A. Montleart and W. Tent. Attaching hooks to furniture.
1846. M. Meisel. Regulating the speed of trains on railways. (A communication.)

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed July 31, 1863.

304. J. Fletcher and H. Bower.
305. A. T. Blakely and J. Vavasseur.
312. T. Bradford.
318. W. T. Weston.

MECHANICS' MAGAZINE.

LONDON, FRIDAY, AUGUST 14, 1863.

STEEL AS A MATERIAL IN THE CONSTRUCTION OF BRIDGES.

WHEN iron was originally introduced into the construction of bridges, it was thought that the natural fitness of things had been violated. Iron was, no doubt, stronger, every way, than stone; it was, perhaps, imperishable, certainly manageable, and, on the whole economical. Yet, not being habitual, it was hard to convince engineers that any combination of iron could constitute a veritable bridge. Of our early engineers many, it is to be remembered, were, at one time, stonemasons, and throughout life they remained faithful to the traditions of the craft. Familiarity with a special material, influences the ordinary modes of thought. We are very well aware who it is that is convinced that "there is nothing like leather." The Americans, accustomed to the general use of wood in engineering structures and in machinery, may be said to *think* in that material; and it is no wonder that all the conceptions of a stonemason should, in like manner, smell of the quarry and the stonecutter's yard. So for years stone bridges (and those of bricks, which are but artificial stones) were many, and iron spans were few. Interminable stone and brick viaducts were erected on our railways; and we believe it to be, even yet, a cherished tradition that for a very heavy traffic, such as that over London-bridge, "there is nothing like stone." But the limit of the practicable width of span is soon reached in stone bridges, and any considerable width requires a great proportionate rise. Kircher, it is true, speaking of stone bridges in China, from 3 to 4 miles long, mentions an arch of the incredible span of 600 ft. The widest stone span, however, of which there is any authentic record, was that of an arch of 251 ft. clear opening, formerly standing over the Adda, at Trezzo, not far from Milan. This great bridge was destroyed for military purposes, but the abutments and the curve of its lower intrados still attest its former greatness. The widest stone arch now standing is one of 220 ft. clearspan, and 57 ft. rise, on the line of the Washington aqueduct, U.S.; and next to this comes the noble arch, of 200 ft., and 42 ft. rise, of the Grosvenor-bridge over the Dee, at Chester. This is justly reckoned a great span, although it would be hardly noteworthy if executed in iron. The old bridge of Vieille, Brionde, over the Allier, in France, has a single span of 183¼ ft., with a rise of 70 ft. 3 in. The widest masonry arch yet executed for railway purposes, is that of 180 ft. span, and 90 ft. rise, over the River Ayr, on the line of the Glasgow and South-Western Railway.

We need not say how far such works, the greatest of their kind, are surpassed by spans of iron. Not considering suspension-bridges, iron spans of 400 ft. are now considered to present no difficulty. We have 460 ft. spans over the Menai Straits, and 455 ft. spans over the Tamar. The River Conway is crossed at a leap of 400 ft. The Vistula is crossed not far from Koenigsberg by an iron railway bridge having six spans of 397 ft.; and that over the Rhine at Cologne has four spans of 344 ft. 6 in. The Mayence has four spans also of 331 ft.; and 330 ft. is the width of the principal span of the Victoria bridge over the River St. Lawrence at Montreal. The Chepstow-bridge has a span of 306 ft.

The limit to the width of span, in any material, is in the weight of the material itself. The late Captain Moorsom obtained the prize in the Cologne-bridge competition for a design for a lattice bridge of two spans of 600 ft. each, and Mr. Fairbairn's design was for a tubular bridge with two spans of 570 ft. 6 in. each; yet it is demonstrable that, at a span of about 1,600 ft., a tubular bridge could bear only its own weight. Steel, of good working and welding quality, has a strength nearly or quite double that of ordinary bridge plates, the strength of which seldom averages 20 tons per square inch, while there is much that probably does not exceed 16 tons or thereabouts—thus, if 1,600 ft. is the limit of span in iron, it should be 3,200 ft. in steel; and if a span of 600 ft. be practicable with the former material, one of 1,200 ft., should be equally so with the latter. To double a given span, whether in iron or steel, requires at least twice the weight, per lineal foot, in the bridge itself; and where the weight of the bridge forms a large proportion of the whole load, the rate of increase is correspondingly greater. Yet a steel bridge of 600 ft. span need not, theoretically, contain more metal in the top and bottom members than an iron bridge of two spans of 300 ft. each, so that, as far as cost is concerned, the difference would consist in that of the cost of equal weights of steel and iron. As, however, a pier would be saved, this saving might be such as to render the steel bridge absolutely more economical in first cost than one of equal length in iron.

It is almost needless to say that steel is not necessarily brittle, as are the qualities used for cutlery. Steel is any combination of iron and carbon which, when heated and immersed in water, becomes harder. Even many commercial irons do this, and as iron is never entirely free from carbon, it is difficult, indeed, to say whether any specific specimen of carbonized iron is to be known as iron or steel. Certain it is that many irons are brittle, and certain marks of steel are nearly as tough as copper. Puddled steel, when it can be had of uniform quality, is not generally brittle; "homogeneous metal," so-called, is but a moderately carbonized steel of well known toughness, and Bessemer metal, although produced by a different process, partakes of the same qualities. The structural value of any metal is its absolute resistance, both to tensile and compressive strains, multiplied into the distance through which these strains act before the natural elasticity of the metal is permanently affected. The great absolute cohesion of steel would not, of course, entitle it to confidence when applied in important works of construction, did it not, also, possess "toughness," or considerable extensibility before rupture. Mr. Mallet has modified the co-efficients adopted by Poncelet, so as to express by **Te** and **Tr** the combined tensile strength and extensibility of a metal respectively at the elastic limit and at rupture, and corresponding co-efficients are also employed for compression at the elastic limit and at the crushing point. Half the strain multiplied into the distance through which it acts, gives a product either in foot-pounds or inch-pounds, expressive of the relative structural value of material when any known standard is taken for comparison. The test of a good steel for bridge plates will be that of high tensile and compressive resistance, combined with a good range of extensibility and compressibility. From the great progress lately made, and still being made, in the manufacture of steel, we may reasonably look for the production of a strong, tough metal upon a scale and at a price which, for bridges of large spans at least, will render it every way preferable to iron.

SMOKE PREVENTION.

THANKS to Mr. W. Williams, and one or two other gentlemen, engineers understand remarkably well how the evolution of smoke from a steam-engine furnace is to be prevented. Nevertheless, a trip to our manufacturing districts demonstrates clearly enough that the comprehension of scientific information is one thing, and its application in practice is another. We might, it is true, pick out one or more stacks in such towns as Manchester, Birmingham, Leeds, or Sheffield even, whose white-washed tops denote to the world beneath, in rather an ostentatious fashion, that the furnaces which supply them are expressly constructed to "consume their own smoke;" but such exceptions only prove the rule, exemplified by the dense cloud which hangs above, that smoke is not yet prevented, and that the last fifty years have done little or nothing to abate an enormous nuisance.

The question—"How is the appearance of smoke at the top of a stack to be prevented?" has long since received a satisfactory answer, which may be summed up in the two sentences, "Less air through the bars," and "More over them." Short as it is, it embodies the result of years of experience. The Patent-office, no doubt, contains the records of many hundreds of inventions, some ingenious and sensible, many quite the reverse, but all having the combustion or destruction of smoke in some way for their object. Fortunately, no complicated apparatus is necessary to accomplish the end in view, and thus most, if not all of these inventions, are not worth the paper they are printed on. They are, nevertheless, strong evidence of the desire entertained in the manufacturing world for many years; that the carrying on of a business which required the consumption of large quantities of coal should not inflict an injury or a nuisance on the surrounding town or its inhabitants: and with our present knowledge, it seems strange enough that there should ever be cause for the infliction of a legal penalty, or that reasons should exist to prevent us from white-washing all our stacks, instead of two or three out of as many hundreds. The question is no longer, "How can smoke be prevented?" but "*Why* is it not prevented?" It is one which, we think, permits of more easy solution than many imagine.

A large number of furnaces exist which cannot possibly be so constructed as to admit air in quantity above the burning fuel, without entailing such a change of form and structural arrangement as would simply render them useless for the object in view. In this class we may place puddling and blast furnaces, and many others which are intended to raise materials to a high heat without exposing them to the action of free oxygen. It is obvious that the introduction of air, anywhere but through the fire-bars, is incompatible with the attainment of the required end. Such furnaces smoke as a necessity, and are likely to continue to do so, unless some very radical changes, of which we see no prospect, are introduced into our iron manufacture. In some other cases of the same kind, the production of smoke might be greatly reduced, perhaps, were it not for the low price of coals, which renders any trifling advantage to be realized not worth the expense. All things considered, we may regard the question as being solely confined to steam boiler furnaces; and when we find that th[e] smoke as much, or more than they did h[alf a] century since, although they are under control of able men, who are well aware saving to be effected by the prev[ention of] smoke, in most of the situations in w[hich] power is employed, the denunciati[on]

a fact without due inquiry becomes absurd. In some few cases, it may, it is true, be a result of ignorance; but in the great majority of instances, on board our steam-boats, in our locomotives, and far and wide through the manufacturing regions, the cause will be found in want of power on the part of the boilers, to meet the demands made on them by overworked engines, and as a consequence, a system of firing which sets the conditions necessary for complete combustion at defiance.

The gases rising from burning fuel cannot be consumed without the admission of a very considerable quantity of air, in a state of subdivision, above the fire-bars. As a consequence, we find that, although the economical power of the boiler is increased, its total power is very considerably diminished—that is to say, a furnace which fulfils every condition required for the complete prevention of smoke, cannot, *cæteris paribus*, produce the same quantity of steam in the same time as one into which the fuel may be heaped without system, and the fire urged without regard to anything but the production of an intense heat. Thus steam-boats, locomotives, and stationary engines, can be counted by the hundred which, to use the popular phrase, "consume their own smoke," to perfection while engaged in ordinary work; yet the moment any extraordinary demand is made on their powers, volumes of dark vapour and unconsumed gases testify to the fact that the smoke-preventing arrangements are either unequal to the exertion, or deduct so much from the gross power of the boiler that they are purposely rendered inoperative for the time.

Theoretically speaking, nothing but cold air should be admitted to a steam engine furnace, for reasons we need not dwell on; but practically, we believe that the greatest advantage would be derived from the introduction of a volume of heated air above the fuel in combustion, in all cases where the fire-box or boiler is too small for the work it has to perform. There is always an ample supply of waste heat, which could be devoted to such a purpose by very simple arrangements. Better hot air than none; and a recourse to this system would greatly diminish smoke without reducing the powers of a boiler.

LOOSE RAILWAY WHEELS.

It is not easy to discover a greater mechanical absurdity than that involved in the system of fast wheels for railway carriages. It needs no abstruse knowledge of mathematics, to demonstrate the impracticability of causing two wheels of the same diameter to pass over different distances in the same time, while they are bound together by a rigid axle, which effectually prevents a corresponding difference in the number of revolutions, unless one or both act the part of sledges. Only suited for travelling on a line of rails geometrically straight, the instant a railway carriage enters on a curve, the wheels become sources of destruction which set economy at defiance, endanger the stability of the permanent way, and throw a serious strain on the axles. The conical shape given to the tyre, and once lauded as a practical remedy for a theoretical blunder, is now well understood to be useless, except so far as it tends to keep the flanges of the wheels clear of the rails. It would be perfect as a remedy only on certain conditions impossible to secure. These are, that all curves should be of the same radius; that the difference between the inside and outside diameter of the tyre was exactly proportioned to the radius of the curve and the gauge of the rails; and that the play of the wheels between the rails should be accurately adjusted, so as to permit the curve to exert its due effect; failing in any one of these, the principle is worthless. Many thousands of miles of railway track are daily hurried over by trains; and it certainly is not exaggeration to assert, that three-fourths of the distance is made up of curves of every imaginable radius, to which it is out of the question to adjust the cones of the wheels which run over them; and, as a result, we find flanges worn away in a few months, tyres deeply grooved, and the surface of rails laminated and abraded, until the iron, strong as ever as a mere girder, becomes useless as a roadway. Fully one-half the expense incurred by the replacement of track might be avoided by permitting each wheel of a pair to act freely for itself.

The cone, to be effectual even in theory, presupposes the existence not only of a given amount of lateral play between the rails, but that this play shall be available in the highest degree on curves. One of the fundamental principles, however, of railway construction is, that the outer rail in such cases shall be raised sufficiently to prevent the flanges of the outer wheels touching it. In order to secure safety, the increase of elevation is always proportionate to the highest speed at which a train is likely to pass round the curve. As a consequence, at slower speeds the inside flanges are brought into contact with the inner rail; so that the conical form of the tyre is injurious rather than beneficial. And even with fast trains the height of the outer rail is intended to, and does approximately as a rule, keep the wheels in the same relation to the track as that which they assume on a straight line. Wheels then cease to deserve the name; they become, instead, sledges of the very worst possible form. Further, six-wheel carriages cannot, under any circumstances, bring the cones of the middle wheels into action, in the legitimate sense; and for anything we can see to the contrary, they at least would be better if made truly cylindrical, with a slight swell at the root of the flange to impart strength.

We have purposely avoided touching on the evil induced by the axles diverging from the radii of the curve, both because it is of itself of less importance, and because the slight play of the bearings in the horn plates compensates for it in some degree.

Even though the cone system worked perfectly while wheels are new, it would still be imperfect, in that the tyres wear rapidly into channels from the small surface which they present to the rails, the tables of which, instead of leaning inwards, are either laid horizontally at first, or shortly become so from the failure or sinking of the sleepers. Thus the passage of a new wheel over a marked rail shows a line of contact perhaps less than half an inch wide. A little sledging round curves soon tells on such a bearing surface as this, and it does not require many trips to more than double it. Wear, once commenced, goes on rapidly, and the tyre, instead of a smooth cone, quickly becomes a grooved pulley; and what then becomes of the much-vaunted conical principle?

Considerable as the evil was even in Stephenson's day, when any expense was incurred (in order to avoid a sharp curve), it now assumes tenfold importance when curves are scarcely considered an evil, so long as they permit a train to be forced round them. Hence a system which might have worked passably well thirty years ago, totally fails to meet the demands made on it now. That it is still adhered to we regard as no evidence either of the intrinsic merit of the principle, or of the mechanical impossibility of replacing it by something better. It is rather a result of a conservatism which is not less admirable in moderation, than absurd when carried to excess. The mere fact of so constructing two wheels that they may revolve freely on a common axis, and yet retain all the working conditions which entitle them to confidence when employed under a railway carriage, presents no difficulty whatever. It settles down into a simple question of expense—which is unimportant in the face of the benefits gained—and weight, which deserves a good deal of attention.

Many inventions for attaining the desired end have been from time to time brought before the public; but we believe we are correct in stating that none of them have ever received a fair trial. We hope to go fully into the more strictly mechanical details of the question at an early opportunity; for the present, we may remark that one of the principal arguments urged against the introduction of loose wheels, is the enormous expense which the application of the system to existing rolling stock would entail. When we reflect, that the process might extend over a series of years by simply replacing old vehicles and wheels by new ones, constructed on different principles, the objection in a great degree loses weight; and in any case, the saving effected in repairs would provide an annual sum sufficient to pay a fair interest on the necessary outlay. The present expense of keeping tyres in running order is extravagant to a degree; and to the attempt to reduce it within more moderate limits, may be ascribed the use of hard brittle iron, instead of the soft tough metal formerly employed. We believe that the abandonment of fixed wheels would soon permit a return to the best fibrous Staffordshire tyres, now abandoned in favour of the hard Yorkshire irons, which are a source of accident which it would be as well to avoid, to say nothing of their destructive influence on the permanent way. Loose wheels have received a partial trial in America, and been spoken of very favourably even in a country where the peculiar "bogie" system scarcely renders a resort to such a plan necessary or advisable.

THE CHAIN CABLE AND ANCHOR BILL.

We regret to state that the prognostications we ventured to form about six weeks ago as to the fate of Mr. Laird's bill for this Session have turned out true; and after being read twice, the measure has been withdrawn, in consequence of its mutilation in Committee. We are, however, informed—from a source that must be reliable—that Mr. Laird intends to re-introduce his bill at an early stage of next Session. The rejection of the bill was perhaps to be expected, as it was at the outset an exceedingly crude measure; and when improved through the representations of Lloyd's and the general body of shipowners, it had scarcely sufficient time to encounter any eventual opposition of a character at all serious. Mr. Laird's bill did not determine a fixed size of chain in proportion to the tonnage of any given vessel; and the mere testing of any small chain and anchor would thus have been a legal compliance with the Act. The delusive character of this clause is evident; and, at the same time, penalties of an undue stringency were proposed to be laid upon the masters and owners of vessels. In many other respects several points involved in the nature of the business were disregarded; making the bill a dead letter to some, and a perplexity to most people. The revision of the bill by Lloyd's Registry and by the Shipowners' Association has, however, resulted in a modification of the

objectionable clauses and an addition of certain others; and there is thus little doubt that this now useful measure will be carried easily next Session. The withdrawal of the bill was mainly owing to the opposition of Messrs. Lindsay and Fenwick, the two members for Sunderland; who therein showed themselves the followers of the Board of Trade—in its usual opposition to any private member's bill.

The necessity for thoroughly testing the chain cables and anchors of ships is now so generally recognized, that measures are being adopted to furnish almost every important port in the country with proving-houses. Another machine will be laid down in a few weeks at Lloyd's proving-house at Poplar, in order to double the amount of work to be turned out. A Joint Stock Company of high local status has lately secured, by a long lease from the Corporation of Newcastle, a site for a testing-house at Walker, midway between Newcastle and Shields. By the end of the year, this establishment will be ready for action, in order to meet Lloyd's extended regulation—making imperative the testing of the anchorage tackle of all classed ships. A company is also being formed for Staffordshire, in order to supply the wants of that important district—where at present so many chains of a bad material are manufactured. Some of the Staffordshire chain-makers have already taken steps to form a company for testing chains; and it is not improbable they will unite with the London Company, now receiving the impetus towards its formation from Lloyd's. The Clyde is also an important seat of shipbuilding, though not of the chain and anchor manufacture, and it will require an establishment to meet the general wants of the district. No measures are at present being undertaken in Sunderland to meet Lloyd's requisition for testing anchors and cables; and as the port of Sunderland will be unprovided with testing machines by the 1st of next January—the date when Lloyd's extended regulation will take effect—all the Sunderland chains and anchors will have to be sent from the Wear to the Tyne to be tested. The Newcastle people will thus at once benefit by the shortgoings of their less far-seeing neighbours, to the injury of the Sunderland chain manufacture.

The delay in the Public Compulsory Act will thus be scarcely of any great consequence, as, by the time it is passed next Session, private enterprise will have made complete preparations for its reception. Most of the above companies are being formed, under the auspices of Lloyd's, by their engineer at Poplar—Mr. T. M. Gladstone.

PETROLEUM GAS.

The following report is from Mr. George Bower, of Huntingdonshire, gas contractor to the Duke of Marlborough, the Earl of Shrewsbury, Viscount Hill, &c.:—

Having had a large quantity of crude petroleum oil placed at my disposal by Mr. A. S. Macrae, of Liverpool, for the purpose of ascertaining its gas-yielding properties, and also whether it could be used along with common coal, wood, or peat, for the purpose of enriching the gases made from these substances, so as to compete with boghead, which is the material now generally used, I am now enabled to make the following observations:—

Before giving the results of the experiments, I think it right to describe the apparatus which I have constructed purposely for these experiments.

The retort is double-acting, 4 ft. long, and of this shape in section Ȣ, and known as the Fitzmaurice retort, the principle being that of the regenerative system, as practised by Malam some 40 years ago, but with this difference of construction—Malam had two retorts, a large and a small one, set one over the other, the coal being placed in the large retort in the bottom, the vapours passed through the smaller one at the top, and those which were not permanently gaseous were made so by their passage through this highly-heated surface.

Although by this process the yield of gas was increased per ton of coals distilled, yet it was at the cost of both the illuminating power, wear and tear, and fuel—in short, the cost was greater than the value of the larger product, and so did not obtain extensive use. This system was applied to coal gas, which of itself has only a moderately illuminating power; and though some of the tarry vapours were arrested, yet the second application of heat to the already formed gas deteriorated its illuminating properties, by causing it to deposit carbon, and thus more than counterbalanced the advantage of an increased yield. The evolution of gas from coal in an ordinary retort is a slow and gradual operation, the outside being first acted upon; and hence it requires six hours to obtain the whole of the gas from 1½ cwt. of coal, with which the generality of retorts are charged; but with oil the vapour is evolved so rapidly, that without a considerable surface for it to pass over, a very great portion of it would be condensed into a thin, black, tarry oil; hence the advantage of the Fitzmaurice retort, which is also equally adapted for coal, wood, or peat, and the gases from which can be enriched with oil.

It has been a common practice, in making gas from oil, to fill retorts with coke, broken bricks, or any material which will give surface, and the oil has been dropped or run into them, or made to traverse through them; but this seems to be a very effective way of absorbing the carbon, to which all gas owes its luminiferous property. The result of a great number of experiments has made me determine that a high heat, with a large surface, is the very worst plan that can be adopted for making gas from oil; but that in order to get the best results, a moderate heat—dull cherry-red by daylight—and the double form of retort without anything in it, give the best results, not for volume of gas, but for quantity of light; in other words, there is more light from 80 cubic feet of gas produced in accordance with the latter plan from the gallon of oil, than from 160 ft. produced according to the former made from the same quantity.

The test of the apparatus is the same as for ordinary coal, excepting that no purifier is required; but the condenser has double the surface of that for coal, on account of the rapidity with which the gas is evolved. A meter to measure the quantity of gas produced, and a gas-holder, complete the apparatus.

Two qualities of oil were supplied to me by Mr. Macrae, one of specific gravity ·805, the other ·910; water being 1.

It may be stated that the higher the specific gravity of the oil the better the yield of gas, and the heavier it is the greater the heat required to get the best results.

I now proceed to consider the cost of gas from petroleum oil, and how far it may be used for this purpose.

The present price of the lighter of the two oils is about 1s. per gallon. I will dismiss the heavy oil, and confine my remarks to that of specific gravity ·805, as it is, upon the whole, more economical to use than the other.

With the present prices of oil the gas cannot be other than very costly, when compared by volume alone against ordinary coal gas; but when all the collateral advantages are taken into consideration, and a comparison instituted upon the basis of quantity of light from equal volumes, then the contrast is not so marked.

The advantages which oil has over coal are in the fact, that it requires no purification, being absolutely free from impurities; hence it may be used in the most sumptuously decorated saloon, library, or picture gallery, without the slightest fear of its injuring anything whatever; the process of making the gas is much more simple, the apparatus to produce an equal quantity of light as that from coal is much less costly, and consequently the wear and tear is also less; and not only is a less quantity required for an equal amount of light, but the heat is considerably less than coal gas.

If the comparison be made as between coal and oil, coal undoubtedly makes the cheaper light by far; but, if it be instituted as between tallow and oil, as ordinarily burnt in lamps, then the light from petroleum oil gas is very much less costly than from either of them.

One ton of oil will produce as much gas as will give the light of that produced from good Newcastle coal; thus where carriage forms the chief item of the cost of the material at its destination, oil may, in such a case, enter into favourable competition with coal; or, where the first consideration is purity, and to have a gas which, for light, shall be more brilliant and powerful than the oil burnt in the solar and moderator lamps, then not only is petroleum superior, but also of considerably less cost.

His Royal Highness the late Prince Consort took great interest in portable gas, and I have in my possession a vase which he had made especially for his own use to contain compressed oil gas. One foot of oil gas will give the light of three feet of ordinary coal gas, and though gas under very high pressure, loses some of its luminous qualities, yet it may be condensed at fifteen atmospheres, and thus become perfectly portable; so that beginning with a gas of three or four times the illuminating power of common coal gas, and condensing a given volume into a fifteenth of its bulk, there is in this fact alone a large field for the use of oil gas for the lighting of railway trains, ships, private carriages, and country houses, where it may not be feasible or policy to erect small gasworks for the supply of gas at ordinary pressures. For instance, the Albert vase already alluded to is of a capacity equal to half a cubic foot, and if charged with oil gas compressed to fifteen atmospheres, it will then deliver 7 ft. and as this is, to begin with, three times more powerful than common gas, its effect will be equal to 21 ft., and will give a light equal to six or eight candles for seven hours.

The daily cost of petroleum oil gas, when made to supply one hundred lights burning for six hours, each light being equal to eight candles, is as follows:—

	£	s.	d.
15 gallons of oil, 1s.	0	15	0
Coke to heat the retorts, 3 cwt., 1s. .	0	3	0
Labour—part of a lad or man's time .	0	1	6
Wear and tear	0	0	9
Interest on capital	0	0	4
Fund to maintain plant in perpetuity .	0	0	6
Net cost of 1,200 cubic feet .	£1	1	1

This is about five times what coal gas would cost on the same scale; but as the illuminating qualities of the 1,200 cubic feet are equal to about 3,500 of ordinary coal gas, the oil does not compare very unfavourably when everything is taken into consideration, so that if the gas be required only for lighting purposes, and not for cooking or heating (for which it is totally inapplicable), then there are very many who will doubtless prefer paying a high price for oil gas, in order to get a light which is absolutely pure, and which, though not nearly so cheap as ordinary coal gas, is nevertheless infinitely cheaper than oil, tallow, or wax, as ordinarily burnt, and without their inconveniences.

The supply of oil in Pennsylvania and Canada, in Moldavia and Wallachia, is practically exhaustless; and as a means of transport to the shipping ports are increased, so probably will the price be reduced, though every day almost is adding a new product obtainable from it, so that it may be some time before the price will be materially reduced.

PRESERVATION OF IRON-PLATED AND OTHER SHIPS.

A process has been invented by Monsieur Jean Pierre Jouvin, Chief Medical Officer of the French Navy, and Professor of Chemistry to the Naval School of Medicine at Rochefort, "for preserving

Iron-plated and other Vessels and Metallic Articles from Oxidation, and Preventing Ships' Bottoms from Fouling." The French Government are now making trial of the process by covering two iron-clad vessels with the preparation.

The invention has been patented in England, and consists (as described by the inventor) in lining the inner surface of ships' sides and bottoms, perfectly scoured, with sheets or lamina of zinc applied directly against the sheet-iron, and there held fast between the latter and the frames. But as iron ships now afloat present some difficulty to the application of such zinc sheathing in the interior of their holds, the internal sides of the hold are first carefully scoured, and afterwards a double coat of a paint made of powdered metallic zinc is applied thereon, which is spread all over from the keel up to a little above the water line. As zinc paint, on account of the fatty matter it contains, does not act as an electric protector with the same efficiency as zinc when employed in the form of sheets, it is necessary to increase the area of the protecting surface.

For iron ships on the stocks, as soon as the keel, the stem, the stern-post, and frame are set up, they receive a thick layer of the aforesaid metallic zinc paint. The boarding of the keel and sides is afterwards proceeded with as usual, care being taken to apply underneath the timber employed a coat of the same paint, or in lieu thereof sheets of greasy felt thickly sprinkled with powdered metallic zinc. The zinc sheets are then applied without difficulty, and become bound with the sheets of iron of the streaks from the keel up to the water-line, and from the stem up to the stern-post, so as to form part with them. The sheets of zinc are held between the sheets of iron which form the stem and the keel, and, assuming the shape of the sheets to be protected, form continuous bands extending right and left and from the bottom upwards, so as to meet and join each other, between the sheet-iron forming the stern-post, and to have their ends in the vicinity of the helm and the water-line. As the riveting takes place at a temperature higher than that of the melting of zinc, and approaching that at which this metal evaporates, part of the sheets around the heads of the rivets would be destroyed; to avoid this defect, the sheets of zinc must be of sufficient breadth and length to cover the sheet-iron to within one-third of an inch of the rivets, without reaching them. The phenomena of dilation could, therefore, freely take place on the preserving plates, the co-efficient of expansibility of these plates being nearly double that of iron.

For those parts of the zinc plates held between the frames and the sheet-iron, in order to ensure a complete riveting of iron on iron, it is necessary to begin by cutting washers or discs, by the ordinary means, in these bands opposite each hole of the rivets. The diameter of these washers must be double that of the rivets, and they are finally replaced by rings of sheet-iron, the diameter and thickness being equal to that of the bands of zinc. The covering bands and the heads of the rivets must receive a thick coat of metallic zinc paint. In the electro-chemical scale, the protecting metal (zinc) coming immediately after the protected metal (iron), it will be advantageous to have the protecting surface as nearly as possible of the same dimensions as those of the surface to be protected. It is found that the protecting bands of zinc, if properly fixed from the keel up to the water-line, may be about two-thirds at maximum, and about one-tenth at minimum of the last surface, provided all the spaces between the zinc bands be covered with the metallic zinc paint. The zinc sheets should measure about one-fourteenth of an inch in thickness for the lower part, and about one-twenty-eighth of an inch for the sides of the hold. When the ship is built, all the parts of iron composing the hold—such as the ribs, keelsons, clamps, transversal bulk-heads, and others not covered by the zinc bands, are carefully scoured, brushed, or otherwise cleaned, and then coated with metallic zinc paint.

To protect the exterior part of the hull immersed from the deposit of marine shells and plants, the inventor proceeds as follows:—He states that turbith mineral (SO^3 $3HgO$) mixed with Prussian blue ($3Fe$ Cy + $2Fe^2$ Cy^3) produces by its contact with the alkaline chlorides of sea-water, one of the most violent poisons known to mineral chemistry, namely—the cyanide of mercury (Hy Cy) in the shape of chlorocyannide of mercury and sodium. He, therefore, first mixes fifty-five parts of turbith mineral with forty-five parts of Prussian blue of the commonest tint, but not adulterated, so as to obtain green powder perfectly homogeneous, and composes the poisonous paint as follows:—Of boiled linseed oil 250 parts; red lead (or any other agent which may cover or adhere as well or better than red lead), which is here used as a mere vehicle for the poisonous compound, 650 to 660 parts; the hereinbefore described mixture 90 to 100 parts. These substances must be well ground together in order to effect a uniform and complete distribution of the poisonous compound throughout the mass of the paint. But as iron possesses the property of reducing mercurial and leaden compounds, this preparation must not be applied direct on the bare metal, all the parts of the hull—namely, the sheet-iron of the keel, cut-water, rudder, paddle-wheel frames, and every part of iron to be immersed or wetted—must be previously coated with two layers of the metallic zinc paint, after being scoured as completely as possible. When these layers of metallic zinc paint are quite dry, the poisonous compound or paint is applied thereon. This poisonous compound may prove also very advantageous if applied to wood employed to secure dikes, embankments, and for marine constructions, to protect them from injury by teredos. The smallest particle of the chloro-cyanide of mercury and sodium produced by its contact with sea salt, suffices to kill instantaneously animalculæ, plants, and even their germs when brought within its influence.

To apply the invention to iron-plated vessels, there must either be placed between the woodwork of the hull and each iron plate a sheet of zinc, the surface of which is rather smaller than that of the iron plate, or this woodwork must be first coated with a thick layer of metallic zinc paint; then each iron plate, previously well scoured, is similarly painted on its inner face, and adapted to the sides of the ship. The ship being finished, the whole of her bottom to be immersed in water is treated in the manner before described—that is to say, first coated with a double layer of metallic zinc paint, and afterwards with the poisonous compound paint. To preserve sheet iron tanks, marine boilers, steam engines, and other similar articles from oxidation, the inventor either applies on them externally zinc sheets, or coats them with a double layer of the afore-mentioned metallic zinc paint.

To preserve the parts of cables and chains stored in wells, where they are oxidized very rapidly, a band of zinc is fastened by screws on each of the rings or links. The metallic zinc paint may be applied to iron articles in general, wherever red paint is now made use of, and as a substitute for it. For ships' bottoms with a copper sheathing, before the sheathing is applied the woodwork is coated over with a thick layer of metallic zinc paint. But in the present case it is more economical to employ powdered cast iron, or, in preference, iron powder, instead of zinc powder, to prepare the metallic protecting paint, as it will protect copper as effectually. Should it be found, however, that the copper sheathing gets foul with barnacles and sea-weeds, it must be coated with the poisonous compound before-mentioned.

HINTS ON PAPER MATERIALS.

In searching for fibre suited for the manufacture of paper, the following hints may be found useful to residents in tropical and other regions.

Any fibre capable of cohesion when precipitated on a draining surface from mechanical suspension in water, after having been reduced to a pure state of capillary subdivision by mechanical action, is fit for the manufacture of paper.

For all practical purposes it may be accepted as a rule, that for the manufacture of white paper all fibre requires bleaching.

Raw fibre may be divided into four classes:—

1. That which is easily reduced and easily bleached.

2. That which is easily reduced, but difficult to bleach.

3. That which is difficult to reduce, but easily bleached.

4. That wherein perfect bleaching involves the integrity of the fibre.

The most profitable shape in which to send fibre to the English market is that of half-stuff (or pulp). Well-prepared bleached half-stuff would fetch £25 per ton in the market.

The best machine for reducing fibre to half-stuff is the ordinary rag-engine, costing about £150, carrying about 2 cwt. of stuff, and requiring a maximum of 7-horse power for driving. The half-stuff would require to be pressed, dried, and packed in bales. For experimental purposes in reducing the fibre, anything smaller than the ordinary sized rag-engine is useless, as the weight of the triturating roll—about 15 cwt.—cannot be dispensed with, so that laboratory experiments are necessarily confined to rough separation and bleaching. Moreover, laboratory experiments, unless conducted with the utmost care and skill, furnish no reliable data for commercial operations. As a preliminary, the character of the fibre ought to be determined in the laboratory—

1st. In relation to its structure, having in view ease in fibrous separation. 2nd. In relation to its chemical constitution, having in view ease in bleaching.

Bleached half-stuff would realize a larger profit than unbleached, always supposing that the process of bleaching, owing to the accident of geographical position or otherwise, did not entail expense extra to that properly belonging to the operation under the most favourable circumstances.

Fibre could be sent into the market as half-stuff unbleached whenever its characteristics were reliably established. B. L.

THE TELEGRAPH TO INDIA.

If mechanical appliances are to be depended upon, and if the most careful and experienced supervision of all relating to the scientific perfection of a submarine cable is of any avail, the whole of England before next March will have at command a means of daily, if not hourly, communication with Madras, Calcutta, and Bombay. The activity of gray shirtings or the dulness of mule twist ought to be known here to the fraction of an anna every morning; and the news from China and Australia anticipated by exactly the difference of time between an overland passage and an overland telegraph, which means the difference between thirty days and five hours. So carefully have the plans been matured, so quietly has the cable itself been manufactured, that the announcement that the expedition will in a few days begin to leave these shores to accomplish such great results, comes upon us with a suddenness that is almost startling, and the notion of being in instantaneous communication with all India soon after Christmas seems almost too good and too astounding to be capable of such immediate realization. Such, however, is at least the object with which the expedition will start, and such, we have not the slightest doubt, is the object which it will accomplish with triumphant success. The Indian Government in making their cable have proceeded so quietly that, except a few electricians and scientific men, the announcement that a cable to connect this country with Calcutta is nearly made will, we fancy, be quite a surprise to our readers.

The political necessity which renders it essential for Her Majesty's Government to be in frequent communication with the great Indian Empire, it is needless here to describe. The Government of such distant possessions as India and Australia can scarcely be carried on in the bureaus of Downing-street without some readier means of conveying instruction than that afforded by the post. Ministers have long been conscious of this fact; and the failure of the attempt to establish electric communication with India *via* the Red Sea, must be fresh in the memory of all. Profiting by the bitter experiences of that unfortunate undertaking, the Government have wisely determined to take the construction and completion of the present line to India into their

own hands. The India Board have placed the general superintendence and control of the line under Lieutenant-Colonel Patrick Stewart, R.E., an officer as well known for his gallantry during the Indian mutiny as for the great services he rendered the Government by the construction and maintenance of the telegraph lines through the wildest districts of Central and East India. For the immediate electrical and engineering superintendence of the line, and also for the arduous task of submerging it, the Indian Government have selected Sir Charles Bright and Mr. Latimer Clark, and under such auspices and supervision its manufacture is now approaching completion at Mr. Henley's telegraph works, North Woolwich. Whatever may be its ultimate fate, it is quite certain that there never yet has been a cable manufactured with such care, or one which, in point of "conductivity" and insulation, comes so nearly up to the standard of absolute electrical perfection. The design and construction of the cable differ very materially from any line hitherto laid. Every operation in submarine telegraphy—even the great Atlantic line—has contributed its quota of valuable experience; for, though successfully laid by Sir Charles Bright and his assistant engineers, in spite of its imperfect construction, it was destroyed by the injudicious electrical treatment it received after submersion. This fact is now so well established, that the cause of the failure of the Atlantic cable may be considered as at rest for ever. The insulation of that line was not very perfect, as may be imagined from the infancy of the science at the time, but yet the electrical power used was such as would infallibly break down even the most perfect cables manufactured at the present day. Of this our readers may judge, when it is stated that the large induction coils first used in signalling between England and America were probably equal in electrical power to 2,000 battery cells, while now it is found inexpedient to use more than two or three cells in working the longest submarine lines in existence. Some of this great power was no doubt used in the vain hope of forcing signals through the line at a greater speed than the very slow and unremunerative rate at which it has alone been found possible to communicate through an unbroken length of 3,000 miles. The result was disastrous, but the experience, though dearly bought, has proved of great value. It has taught electricians the value of moderating the power used in working lines, and, above all, has pointed out the imperative necessity of having no single section of a submarine line of more than 600 miles in length. To lay long submarine cables in a continuous length without intermediate stations has been found to answer no other purpose than that of greatly diminishing the speed of working, and multiplying every imaginable risk both of manufacture and submersion. The Indian Government, acting under the judicious counsel of their scientific advisers, have wisely determined to divide the Persian Gulf cable into three sections, though its total length will not exceed 1,500 statute miles.

The faults which led to the destruction of the Red Sea line were of another character. Though it was manufactured and tested with a care greatly superior to that taken with the Atlantic cable, it was submerged in a way which rendered its ceasing to work a question of a few weeks more or less. Sheathed in a covering of small wires, quite unprotected from corrosion, it was laid without any allowance for "slack" cable to fall into the irregularity of the bottom of the sea. It consequently lay strained across the points of the inequalities, with a tension of several thousand pounds. As the unprotected wires rusted away, and the suspended portions of the line became loaded with coral and barnacles, the whole line crumbled into hundreds of pieces by its own weight. This is no mere hypothetical opinion, but a fact, which was amply proved by the expedition to the Red Sea in 1861, under Mr. Latimer Clark. There can be little doubt that the same cause led to the temporary failure of the Malta and Alexandria line, as well as that laid for the French Government between Toulon and Algiers.

To obviate this cause of danger, which, in the above-mentioned lines, has probably occasioned a loss of property to the value of over a million sterling, the Persian Gulf line is cased in twelve No. 7 gauge hard-drawn iron wires, thickly galvanized, so as effectually to prevent their corrosion. But, in order to secure more effectually the permanent stability of the line, the whole finished cable is thickly coated with two servings of tarred hemp yarn, overlaid with two coatings of a patent composition invented by Sir Charles Bright and Mr. Latimer Clark. The composition consists of mineral pitch or asphalte, Stockholm tar, and powdered silica, mixed in certain proportions, and laid on in a melted state. While yet warm it is passed between circular rollers, which give it a round, smooth surface. When quite cold this forms a massive covering of great strength and perfect flexibility, totally impervious to water, and incapable of being destroyed by the minute animalculæ which exist in such abundance in warm latitudes, and which, when the cable is not protected against their attacks, eat every atom of the hemp, as in the case of the cable laid between Toulon and Algiers. Galvanising the wire is in itself an almost perfect protection from rust—certainly for many years, as the good condition of the cable picked up off the Kooria Mooria Islands, a part of which was galvanised, showed, as far as the galvanising was concerned. But, with the final protection both from rust and animalculæ which Bright and Clark's compound affords, there appears to be no reason why this cable, when once laid in shallow or deep waters, should not remain good for a hundred years to come. The copper conducting wire is composed of four segments, drawn into a hollow tube in such a manner as to appear like a solid wire. By this means all the advantages of a strand wire are combined with the condensed bulk and small surface of a solid one. The copper from which the wire is drawn is especially selected by the engineers for its high capacity for conducting electricity. It is, perhaps, not generally known that different samples of copper vary as much as 50 or 60 per cent. in this respect—that is, some specimens of copper wire will conduct electricity with greater facility than other specimens of double the thickness, though physically there may not be the slightest difference by which you can distinguish one from the other. This wire, which is nearly one-eight of an inch in diameter, is then covered by the Gutta Percha Company with four distinct coats of gutta percha, and four coats of Chatterton's compound, laid on alternately. This "core," as it is termed, is then tested in cold water, at a temperature of 90 deg., and then under a pressure of 600 lb. to the square inch. After passing through all these ordeals, the loss by leakage through the gutta-percha covering does not exceed one-hundred-millionth part of the current of electricity passing through the conducting wire in every nautical mile. To such minute perfection has the system of testing adopted by the engineers been carried, that the loss of one-thousand-millionth part of the current by leakage could be detected and estimated on the instruments. In the present state of the insulation of the cable the loss by leakage in working each section of the line will not exceed one-four-hundredth part of the electric current sent through the conductor—a condition of insulation which we believe has never been equalled by any cable hitherto manufactured.

Before being sheathed at Mr. Henley's works the coils of gutta-percha core, which are in three-mile lengths, are again tested under water for insulation and for resistance of conductor, therefore if any injury should have occurred to the fragile gutta-percha covering of the wire during its transit from the Wharf-road to North Woolwich it is detected before the cable is made up, and then the process of sheathing them in their outer covering is commenced. The first coating outside the gutta percha is twelve thick strands of wet hemp, and over these again come twelve solid No. 7 gauge wires, which have been most carefully galvanised by Mr. Henley. The outer covering of iron wire is generally the last which a cable receives, but in this instance, as the line is to be laid in comparatively shallow water, the wires themselves, though galvanized, are to be still further protected from their most formidable enemy, rust, which is done by the coverings of Bright and Clark's composition already described.

During the whole time the cable is at Henley's the current is kept always through it, so that the slightest possible defect in the wire can be detected. In addition to this the very able electrical staff test every portion regularly twice a day for insulation and resistance of conductor. When everything has been done which the most jealous care and the most fastidious scientific skill can suggest, it is passed out on the river side of Mr. Henley's factory and coiled away in tanks filled with water; and even here perpetually watched and tested. There are upwards of 900 nautical miles of it thus manufactured lying at Mr. Henley's works—huge coils of thick black-looking rope, nearly 1¼ in. in diameter, weighing nearly 4 tons to the mile, and 2½ tons in water, and costing as nearly as possible £200 p[illegible] mile—the cheapest, strongest [illegible], electric[illegible] speaking, the most perfect [illegible] is ever [illegible] been made. Three hund[illegible] [illegible] of the same kind have ye[illegible] [illegible] which, however, the gre[illegible] factory are quite equal—in the time that yet intervenes before the last ship which composes the expedition will leave this country in September. We have hitherto spoken of this cable as the Indian wire, but, strictly speaking, it ought to be called the Persian Gulf line, and it is down that route it is to be laid to connect Kurrachee with the present land line to Constantinople. Colonel Stewart has himself during two years travelled through and examined the various overland routes which have been from time to time suggested for a part of this line across the Turkish portions of Asia Minor. One of these has been selected from the greater ease with which land lines are erected and kept in repair as compared with submarine wires, and also because along at least three-fourths of the entire route the Turkish Government have already established, and keep in admirable working order, a telegraph from Constantinople to Bagdad. This land line runs from Scutari on the Bosphorous across Asia Minor to Diarbekir, thence to Mosul (the ancient Nineveh), and thence to Bagdad. It happens, however, that over the broad tract of country which intervenes between Bagdad and the head of the Persian Gulf, along which this submarine cable to India is to be laid, various predatory tribes of Arabs claim a sovereignty, and fight for it with more or less success, and over these lawless vagabonds of the desert the Porte has no manner of control. Always quarrelling among themselves, they agree only on the one point of disobeying and defying their nominal lord, the Sultan, which they always do with impunity at least, if not success. These people will require skilful handling, and the land line from Bagdad will probably be taken along the frontiers of Arabia, through the territories of the most powerful of the tribes, who are able to protect it against all comers, and whom a subsidy of £1,000 a-year will at once render most zealous. By this route, for a length of some 300 miles, it will pass to the head of the Persian Gulf at the estuary which marks the junction of the Tigris and Euphrates—a miserable Eastern township, called Shat-el-Arab.

It is not intended, however, to rely solely upon this land route. Another land line will very probably be taken from Bagdad over the frontier of Persia to Teheran, thence to Ispahan, and so on by Shiraz down to the shore of the Persian Gulf at Bushire. Thus, even in the case of the Arabs proving refractory, there will always be the land line through Persia to Bagdad, and so on to Constantinople and England. From the estuary at Shat-el-Arab the submarine portion of the line is to be laid in three sections; for, though the length of the whole is only 1,250 nautical miles, yet the Government have most wisely determined to avoid the fatal dangers which always beset telegraphy through long deep-sea routes by making no less than three breaks at the stations at which the cable will be landed. The first length will be from the head of the Persian Gulf at Shat-el-Arab to Bushire, a distance of 170 miles, along which the cable will be submerged in from 20 to 25 fathoms of water. The next length will be from Bushire to Mussendom, a bold, desolate, stony headland on the coast of Arabia. This section will be 440 miles long, and submerged in from 30 to 35 fathoms of water. The third length will be from Mussendom to Guaddel, a small city on the Mekran coast, on the frontier of the Kelat territory. This portion will be 400 miles long, and laid in from 40 to 50 fathoms of water. From Guaddel, a short length of land line is now almost complete along the coast, giving direct communication with Kurrachee, and thence all over India to the very frontiers of Burmah.

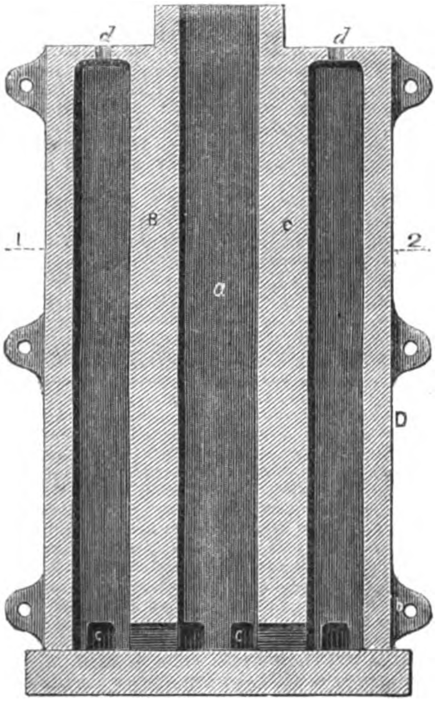
At all these breaks or stations in the Persian Gulf the extreme shore ends will be very massive, coated with galvanized iron wire of almost tenfold strength, and weighing as much as eight tons a mile. In certain portions of the route near Bussorah, where there is any danger to be apprehended from small coasters anchoring, the weight of the line will also be increased by the extra thickness of its wires to nearly nine tons a mile—enough to shield it from any risk from the little anchors of the native boats which are likely to come there. In short, as far as depends on minute care and a wide scientific experience, the whole cable is likely to be as perfect as skill or ingenuity can make it. The vessels which are to take this line will probably leave England ab[illegible] end of next month, arriving on the scene [illegible] [illegible]tions in the Persian Gulf in January [illegible] [illegible]he best time of year in which to lay [illegible] process of submerging it and [illegible] [illegible]nds is not likely to occupy more [illegible]. The total cost of the sub[illegible] [illegible] line will be less than £350,000 [illegible] [illegible]f laying it.—*Times.*

JOHNSON'S IMPROVEMENTS IN INGOT MOULDS.

THE following invention for improvements in ingot moulds, has been recently patented by Mr. J. H. Johnson, of 47, Lincoln's-inn-fields, Middlesex. The invention relates to a peculiar construction and arrangement of moulds to be employed in the casting of ingots of steel or other metals, and consists in making such moulds syphon-shaped, the metal being first poured into a main compartment, which communicates at its lower end only with one or more other compartments by a lateral aperture or apertures, the metal rising in such other compartments slowly and steadily, although poured rapidly into the main or filling compartment. Each of the compartments in connection with the main compartment is closed at the top with the exception of a small aperture for the escape of the air and gases. Any number of these compartments may be combined together in one apparatus, which is composed of several parts held together by bolts and keys, or otherwise, so as to be readily separated for the purpose of opening the several moulds when the ingots are to be removed.

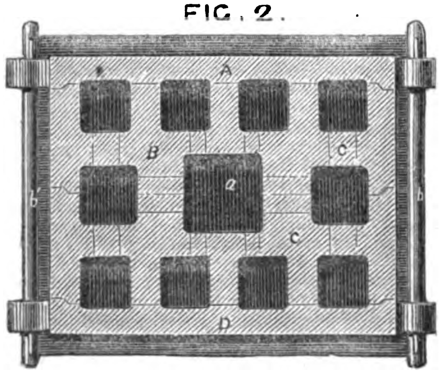
Fig. 1 of the accompanying drawings repre-

FIG. 1.



sents a vertical section, taken through the centre of the improved mould; fig. 2 is a horizontal

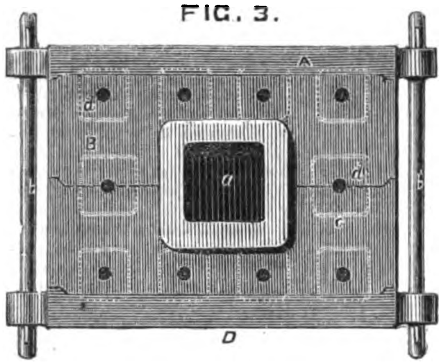
FIG. 2.



section of the same, taken along the line 1, 2; and fig. 3 is a plan of the top of the mould.

This mould is composed of four parts, A, B, C, and D, held together firmly by the key-bolts, b, b¹, and comprises eleven distinct compartments or chambers, the whole of the ten chambers which surround the larger central or main chamber *a* communicating with that chamber at their lower extremities by the openings or passages *c*, *c*. The upper ends of the smaller chambers are closed, with the exception of a small vent hole *d* left therein. The entire mould is made to open or separate into four parts, in such a way that after the ingots have been cast they can all be easily removed from their respective

FIG. 3.



chambers, the lines of division being made to pass through the whole of such chambers, as shown in the drawings.

In using this mould, its parts are first bolted together, as shown, and it is then placed on end upon a flat plate or block of metal (see fig. 1). The molten metal is then poured rapidly into the mouth of the central or main chamber *a*, and rises slowly in all the other chambers, entering therein by the openings *c* at the bottom. As the central chamber rises a little higher than the rest, a slight pressure will be exerted upon the metal in the surrounding compartments, and one mouth alone requires to be covered—namely, that of the compartment or main chamber *a*. When set it is simply requisite to draw out the key and withdraw the bolts, when the mould can be opened, and the several ingots removed. It is obvious that the moulds might be modified in form and number, and in the means adopted for holding the parts together without departing from the nature of this invention.

GAS FROM CANNEL AND FROM COAL.

THE following analysis of the comparative value of gas made from coals and cannel is by Dr. Andrew Fife, Professor of Chemistry, King's College, Aberdeen:—

A ton of English caking coal yields, on an average, at gas-works, 8,000 feet of gas; and though a larger quantity was given with my apparatus, yet we must take 8,000 as the quantity on a large scale. The value of the coal is taken as 1.

The Wigan cannel yielded 9,500 and 11,500; the value of the gas, bulk for bulk, being the same, viz., 1·85 to the former as 1. Now, taking into account the quantity of gas afforded, the value of the coals for yielding light, by the consumption of their gases, is as 2·23 for the one quantity, and ·25 for the other. Taking the average, we state the value of English cannel coal as 2·35, or say 2½ to Newcastle coal as 1.

The following analysis of the cannel raised by the Ince Hall Coal and Cannel Company, is by Mr. John Leigh, M.R.C.I., Consulting Chemist to the Manchester Corporation Gas-works:—

Carbonic oxide and aqueous vapour	1·53
Olefiant gas and divers hydro-carbons	8·50
Atmospheric air	4·32
Nitrogen	0·19
Hydrogen	40·30
Light carburetted hydrogen	33.83
Carbonic acid	11.35
	100·02

Quantity of gas produced ... 11·673 cubic feet.
Specific gravity of gas... ... 5·20 ,,
Coke produced from 1 ton of cannel, 13 cwt. 0 qrs. 13 lb.

This cannel is used by the chief gas-works of this country, including London, Liverpool, Manchester, and Birmingham; and by the principal foreign gas-works, both on the Continent and in North and South America.

The analysis of the same Company's gas coal, made by Mr. J. E. Clift, Engineer to the Pagoda Gas-works, Birmingham, gives:—

Carbon, from 100 parts	84·50
Hydrogen ,,	5·14
Oxygen ,,	2·10
Nitrogen, ,,	2·20
Sulphur, ,,	0·33
Ash, ,,	4·12
	98·39
Loss	1.61
	100·00

Products obtained from one ton of gas coal, being the average results obtained from using 300 tons in making gas:—

Gas produced, 10,200 cubic feet; illuminating power—one Argand burner consuming five feet per hour—thirteen spermaceti candles of six to the pound; specific gravity, 462; atmospheric air being 1·00. Coke produced, 13 cwt. 3 qrs., or 44 imperial bushels; suitable for ironfounders, brassfounders, and maltsters. Ammoniacal liquor produced, 20 gallons; 1 gallon requiring 10 oz. of the sulphuric acid of commerce to saturate it. Tar produced, 10 gallons.

Purification of the gas:—1,000 cubic feet of gas requires 12½ lb. of lime for its purification, which shows it to be comparatively very free from sulphur.

The other impurities of coal gas are not more abundant than in that made from other coals.

A further analysis of the same Company's gas coal, made by Professor Thompson of London, gives:—

Specific gravity	1·270
Coke, per cent.	65·2
Volatile matter, per cent.	34·8
Cubic feet of gas, per ton, gross	11,400·
,, ,, ,, purified	11,200·
Impurity per cent. in gas	1·8
Specific gravity of purified gas	406·
Illuminating matter condensible by bromine, per cent.	4·25
Carbonic oxide in purified gas, per cent.	4·

Illuminating power of the gas, burnt at 5 ft. per hour, equal to 13·8 spermaceti candles, each consuming 120 grains per hour.

Heating power of the coal:—1 lb. will convert 15½ lb. of boiling water into steam.

GREAT BLOWING ENGINE.

THE following description of one of the largest blowing engines in America cannot fail to prove interesting to many of our readers. We extract it from the Philadelphia *Engineer*. The engine was erected in the latter part of the year 1860, and has, we believe, proved perfectly successful:—

The pressure at which our large blast furnaces are blown has been generally increased from 2½ lb. up to 10 lb. to the square inch; and some of the largest furnaces in the world are now working at the latter pressure, and running off the enormous quantity of 280 tons of pigs weekly. The efficiency of a blowing engine is not, therefore, exactly in proportion to the size of its blowing cylinder, since, at the high-blast pressures, which now prevail, a given quantity of air is rendered more effective for the purposes of the furnace than a larger quantity admitted, as formerly at 2½ lb. pressure. The largest blowing engine in the world, so far as mere bulk is concerned, is one at the Dowlais Ironworks, in South Wales. It has a 55 in. steam-cylinder, with a stroke of piston of 13 ft., while the blowing cylinder is of the enormous diameter of 12 ft., the stroke being also 12 ft., or 1 ft. less than the stroke of the steam piston. The beam, which is centered unequally, to allow for this difference in stroke, is 40 ft. between end centres. The six boilers have 8,414 square feet of heating surface. The next largest blowing engine of which we have any knowledge is that of Mount Savage, Maryland, and built at the West Point Foundry. This has a steam cylinder 56 in. in diameter, and a stroke of piston of 10 ft., the blowing cylinder being of 126 in. bore (10 ft. 6 in.), and 10 ft. stroke. This

engine was intended to work with steam of 60 lb. cut off at one-fourth stroke. From what we have heard of it, we judge that its performances have not been altogether satisfactory. The most *powerful* blowing engines yet made have been constructed by Messrs. I. P. Morris and Co. of this city; and these makers have obtained a reputation for the construction of machinery of this class, not inferior to that of Harvey (of Cornwall, England), for the construction of pumping engines, Whitworth, of Manchester, England, or Sellers, of Philadelphia, for the construction of machine tools, nor to that of Baldwin or Rogers for the construction of locomotives. Messrs. Morris and Co. have made several very large blowing engines for the Lehigh Crane, Thomas, Scranton, and other iron companies: one pair for the latter company having 110-in. blowing cylinders, with 10 ft. stroke. These, however, have been removed, since the great increase in the pressure of the blast, and smaller blast pistons are now worked with the same steam power.

An engine, the 500th made by these builders, has been constructed at their works at Port Richmond, in this city; and for combined size and power it surpasses anything yet attempted in the construction of such machinery. It is one of a pair erected at two new furnaces building by the Thomas Iron Company at Hockendoqua, Lehigh county, in this State. The furnaces are 18 ft. in the boshes and 60 ft. high, and are expected to run off 300 tons of iron a week. Messrs. Morris have introduced a plan of blowing engine corresponding to the Bull engine used for pumping the steam, and blowing cylinders being placed in the same vertical line, with both the blast and steam pistons on the same rod. Notwithstanding the economy and excellent success of this arrangement, the Thomas Iron Company have chosen to incur the expense of a beam engine. So far as structural grandeur is concerned this choice is not to be regretted, although we doubt if it can be justified upon any grounds of mechanical expediency. The engine, upon the plans completed by Messrs. Morris' draughtsman, Mr. Davis, is, therefore, of the following general plan and dimensions. The piston rod of the upright steam cylinder, which is 66 in. in diameter, has a stroke of 10 ft., and is connected to one end of a beam (made in pairs), 30 ft. 10 in. between centres. The blowing cylinder, the piston of which has 10 ft. stroke also, is 108 in. in diameter. At the steam-end of the beam it is prolonged 3 ft. 1 in., and a pin for the attachment, on each side, of a connecting rod, is inserted at a distance of 18 ft. 6 in. from the main centre. The fly-wheel shaft is supported in boxes on the bed plate of the engine, in front of the cylinder and steam chests, and but a few inches above the stone foundation. The air-pump, condenser, &c., are placed below in the usual manner. The boilers for supplying steam for this engine are heated by the waste gases from the blast furnace. There are 6 boilers, each 3 ft. in diameter and 80 ft. long; and beneath each one and connected with it is a smaller boiler, or "heater" as it is called, 2 ft. in diameter and 60 ft. long. As the waste gases are more than sufficient for the production of all necessary steam, it is worked at full stroke, no economy being attempted by working expansively. The working pressure in the boilers is 50 lb.; and with the vacuum obtained by condensation, the effective pressure on the piston will probably be 55 lb. to the square inch. The engine is expected to make 20 double strokes a minute, equal to a speed of piston of 400 ft. per minute, and assuming an effective pressure and vacuum, at this speed, of 50 lb., the power actually exerted including that expended on the friction of the engine, would exceed 2,000 horses.

The whole engine sits on a heavy bed-plate, which rests on stone masonry, 10 ft. in depth. The steam cylinder is 1½ in. thick. The piston is 15 in. deep at the centre, and has two outside rings of cast iron, each 4 in. deep and ⅞ in. thick, and one inner ring 8 in. deep and ⅞ in. thick. These rings are set out by 12 semi-elliptic springs, in the same manner as locomotive pistons. The piston rod is 7 in. in diameter. It is not keyed into the cross-head, but is turned cylindrically to 6½ in. in diameter where it goes through, its bearing in the cross-head being 18 in. long. Above this the rod is held by a single nut 7 in. high, screwed upon a square-threaded screw on the rod, and further fastened by a pin. This mode of fastening is dictated by the engineer of the Thomas Iron Company. The cross-head is guided by slides, the wearing faces of which are 4 in. wide on the two sides, and 2½ in. on the edge. The slide brasses or ribs are 16 in. long. The cross-head is connected in the usual manner, by links, to the beam. The support of the beam is a cast-iron hollow tower with open sides. This tower is cast in four sections. It is 11 ft. 6 in. square at the base, and the height to the centre of the plummer block, and including the bed plate, is 33 ft. The sides of the tower are 1½ in. thick, the beads being 2 in. thick. A heavy Egyptian cornice runs around the tower below the plummer block. The whole weight of this tower is about 74,000 lb. The beam is double, or in pairs, each casting being about 33 ft. 11 in. between extreme centres, and 7 ft. deep at the centre. Both beams are cast solid or without open work. They are 1½ in. thick, the flange around the edge being 10 in. wide and 4 in. thick, as is also the centre rib in which the pin for working the air-pump is fixed. The beams are 3 ft. 11 in. from centre to centre. The main centre pin, by the desire of the engineer of the Thomas Iron Company, is of cast instead of wrought iron. It is 10 ft. 2 in. long, each journal being 20 in. in diameter, and 24 in. long. The bearings in the plummer blocks are of hard brass, 2 in thick. The wrought-iron pin, fastened in the prolongation of the steam-end of the beam, for the attachment of the connecting rod, is 12 ft. 6 in. long (the two connecting rods working on the outer sides of the two fly-wheels, being 11 ft. 6 in. apart from centre to centre). This pin is 13 in. in diameter through and between the halves of the beam, the connecting-rod wrists being 9 in. in diameter, and 10 in. long. The connecting rods are of forged iron, 31 ft. long from centre to centre, 9½ in. in diameter at the middle, and 6 in. at the necks. They are trussed in the plane of their motion, as is usual in large connecting rods. It strikes us as singular that engineers have not yet begun to make such large rods flat-sided, as has been long since done in the case of locomotive connecting rods. Such a form is what is needed. It will be borne in mind that, when the engine under notice is in regular work, but little steam can come upon the connecting rods, unless at the extreme ends of the stroke; but in case the strain be shut off, and a few strokes be made by the momentum of the fly-wheel, the whole resistance overcome in the blast cylinder would be represented by the strain transmitted through the connecting rods, which require, therefore, to be as strong as if the whole power of the engine were being constantly transmitted through them. The main shaft, just in front of and nearly at the base of the cylinder, is 20 in. in diameter, and carries a fly-wheel at each end 27 ft. in diameter, and weighing 30 tons each. The hubs of these wheels are 8 ft. 11 in. in diameter, and have a bearing of 22 in. on the shaft. They are 16 in. thick elsewhere. They are bored with radial sockets to receive the inner ends of the ten arms, these ends being turned to fit the sockets, and secured therein by keys—the arrangement generally adopted by Messrs. Morris and Co. The rim of the fly-wheel, 10 in. on the edge and 14 in. on the side faces, is cast in sections, each section being cast whole with one of the arms.

Looking now to the other end of the engine, the blowing cylinder, 108 in. (9 ft.) in diameter, is 1½ in. thick. Its piston is packed with cast-iron rings, which are to be run for a year or two, to get a smooth surface in the cylinder, after which wooden packing will be substituted. The piston rod of the blowing cylinder is 8 in. in diameter, and is connected by links to the end of the beam. The top and bottom heads of the blowing cylinder are gridironed, so that more than seven-eighths of their entire area is either inlet or outlet opening for the air. The valves are of leather, with a thin sheet-iron back, and opened as if hinged at one side, all the valves closing by their own weight. There are 27 large inlet valves in each cylinder head, each divided into a great number of small openings. The blast receiver into which the air is forced is 10 ft. in diameter and 40 ft. high. 630 cubic feet of air (measured at atmospheric pressure) is blown at every stroke, giving, say, 25,000 cubic feet per minute, at the ordinary rate of working. The ordinary pressure of the blast is to be, we believe, 8 lb., although the engine is built for a regular pressure of 10 lb.

The steam valves are of the double-beat, or steam-boat kind, the steam valves being 14 in. and 13 in. in diameter, and the exhaust valves 14 in. and 15 in. The rods for lifting the valves stand exactly over the main shaft, and the lower end of each rod carries a cast-iron roller, 8 in. in diameter and 3 in. wide, upon which a suitably-shaped cam on the main shaft strikes at each revolution. The valve motion, therefore, is the most direct possible, no eccentrics, eccentric rods, hooks, or rockers being employed. The air pump is 3 ft. 6 in. in diameter, the bucket having a stroke of 6 ft. 3 in. The air-pump rod is cased with copper, as a protection against bad water at the works, and is 4½ in. in diameter at the outside. The engine with all its attached parts, but exclusive of boilers, is estimated to weigh upwards of 650,000 lb.

STEAM COAL USED IN THE NAVY.

The consumption of coal in the Navy is now becoming so considerable, by reason of the increasing proportion of steam-vessels, that coal-owners will naturally look in this direction for an extension of their business. This subject having lately been brought under our notice, we believe that a statement of some facts, which we have ascertained with regard to it, will not be without interest to many of our readers.

Supposing the case of a coal-owner, who was working a mine that yielded what he knew to be, or what he had every reasonable grond for believing to be, a good steam coal, how was he to proceed in order to have it brought into use for the Navy? This question arises, first of all, because the use of certain selected coals in the Navy, by sanction of the Admiralty, establishes a kind of prestige, which is, doubtless, not without considerable influence in determining what kinds of coal are used for steam purposes in the vessels of the commercial navigation companies.

The Admiralty has a list of certain kinds of coal which they have recognized as applicable for use in the Navy, in consequence, it may be presumed, of their being considered superior to other kinds of coal for that purpose. But it may easily be supposed that as the working of coal progresses and developes, this list will not comprise all the coals that are, on these grounds, entitled to be regarded as superior steam coals. How, then, can the quality of a new kind of coal be established, so as to become entitled to be placed upon an equality with those recognised by the Admiralty; and how can a recognition of that equality be effected in such a manner as to ensure the coal being placed on the Admiralty list?

We find upon inquiry that the Admiralty adopt a system of trial before placing any coal upon their list as recognized to be suitable for the purposes of steam navigation. It is at the option of the Storekeeper-General of the Admiralty to sanction or refuse such a trial of a coal being made. If the evidence given to him of the quality of a coal is such as to induce him to order its being tested, the trial is made at the Woolwich Dockyard, at the cost of the applicant, and according to the results obtained the coal is or is not placed upon the list.

But so far we have been able to learn, the mere placing of a coal upon the Admiralty list does not by any means ensure, or render more probable, the use of these particular kinds of coal in the Navy. The Admiralty list of coals is kept private, and in practice they adhere to a plan recommended some years ago by the Commission who examined the question as to the coals best suited for use in the Navy, of restricting themselves to Welsh coals exclusively. The only kinds of coal for steam purposes for which tenders are received by the Admiralty are Welsh coals.

There is, however, reason to believe, as we have often shown in the *Journal*, that there are many of the North Country and other coals that are in every respect as well adapted for use as steam coals as the coals of Wales, if not in many respects better. In many cases also a mixture of North Country coal with the Welsh coal is highly advantageous, and has consequently been largely practised in some steamers. There appears, therefore, to be an undue preference shown to the coals of Wales, and the coal-owners of the northern districts have good reason to complain of being precluded from participating in the advantages that are now entirely enjoyed by the Welsh proprietors.

There are also many other kinds of coal worked in Yorkshire, such, for instance, as some of the Silkstone coals, which deserve, at least, to be tried, as regards their applicability for steam purposes, and which would, in all probability, be found worth more notice in this respect than they have yet received.

The very careful experiments made at the instance of the Newcastle Colliery Association, some years ago, fully established the fact that in the [illegible] tion of coals made for the Admiralty the [illegible] and excellence of the coals of that [illegible] fully appreciated, and that the [illegible] conducted in such a manner as not to [illegible] a fair comparison of them with the [illegible] This question is one not only of [illegible] national importance, and on this [illegible] that in referring to it we may [illegible] tribute towards its being more [illegible] in a manner consistent with its [illegible] *ing Journal.*

BILLINGHURST AND REQUA'S PORTABLE BATTERY.

BILLINGHURST AND REQUA'S PORTABLE BATTERY.

Letters Patent have been granted to Mr. W. Billinghurst and Mr. J. Requa, of Rochester, in the State of New York, for the invention of an improved portable battery.

Fig. 1 of the accompanying drawings is a plan or top view of the invention.

Fig. 2 is a vertical section taken through the parts in the direction of the line *y*.

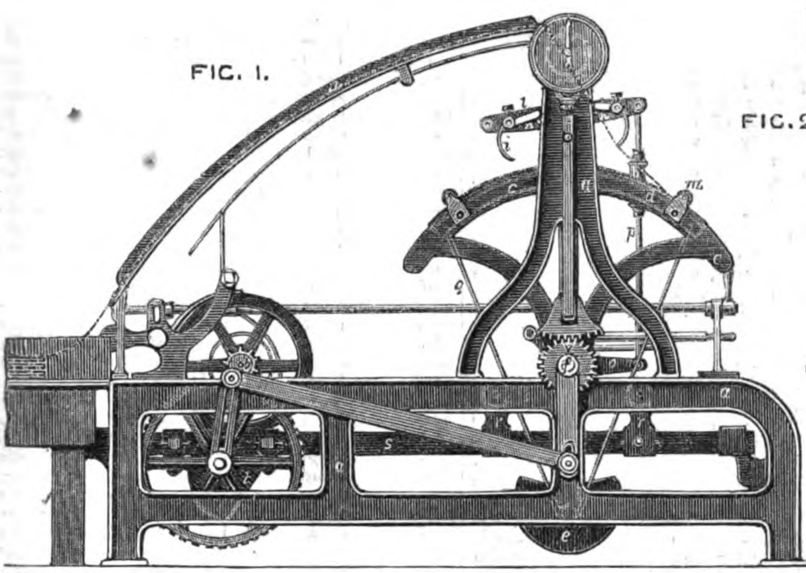
Fig. 3 is a rear elevation of the cartridge holder or clamp, shown open, and containing the cartridges.

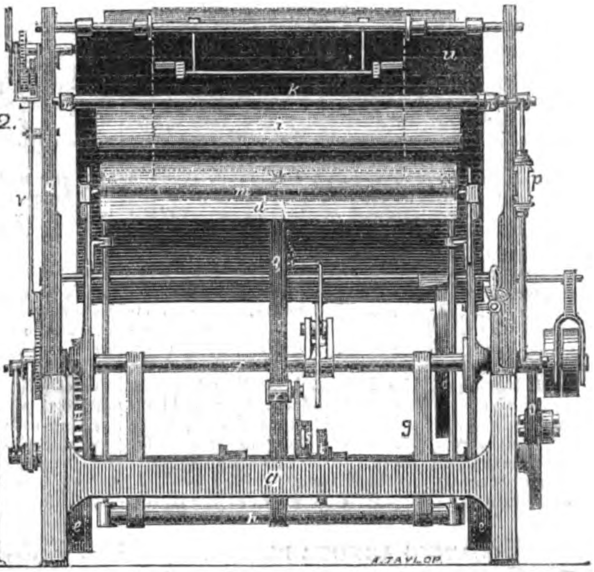
Fig. 4 is a longitudinal central section of the cartridge case, breech bar, and part of the barrel.

Similar letters of reference indicate corresponding parts in all the figures.

The nature of this invention consists in a series of barrels, to be loaded from the breech and fired nearly simultaneously, the barrels being fitted so that they can be diverged more or less at pleasure to regulate the spread of the balls as fired; and the construction and operation of this invention is as follows:—The bed *a* is of iron, and may be of skeleton form. There is a recess made in the upper face of the bed transversely, to receive the pivot shanks or projections *c* of the barrels *b*; this recess is formed on the front side circularly under each barrel, as seen by dotted lines, fig. 1, a portion of one barrel, the clamp *d*, and of the bar *e*, being broken away for that purpose. Each barrel is pivoted to the stock by a screw or bolt *f* passing through the shanks *c*, and the shanks being held down by the plate c^1. The centre barrel of the series is fixed to the bed *a* by a screw or otherwise. A ring *h* is provided on each barrel and fitted to slide, except the two end rings encircling the outer barrels which are fixed thereto. They are all pivoted to the bars *i* (by threaded shanks *j* and nuts *k*), and the said bars are placed diagonally under the barrels, as seen in fig. 1, and are halved together, forming a hinged or toggle joint under the centre barrel, where they are connected to the rod *m*, and by that to the lever *l*. By moving the lever *l* towards the rear of the battery, the barrels are diverged or radiated to cause the balls, when fired, to spread. The breech bar *e* is made solid, and is entirely detached from the barrels and also from the cartridges; there is a hole *s* drilled through it longitudinally, as indicated by the dotted lines in fig. 1, and branches leading therefrom to the side of the bar opposite each barrel, and one from the cone f^1 intersecting the branch opposite. The bar is countersunk at the mouth of each branch to fit the spherical form of the heads h^1 of the cartridge cases, as shown in fig. 4; the ends of the hole or tube *s* are closed by the transverse pin 6. The flame passes from the cone f_1 to the cartridge opposite, and from that back into the tube *s*, and communicating through all the other branches, produces a simultaneous discharge. There is a cap piece *o* at each end of the breech bar *e*, which slide in slots, indicated by the dotted lines, made through the side pieces *n* for that purpose; the breech bar is connected to one of these cap pieces by two dowels (at *r*), and to the other by the sliding bolt a^1, which allows the bar to be removed at any time; and in case of a forced abandonment of the battery it should be taken away, thus rendering the battery entirely useless to its captors. The plate *p* is hinged at each of the front corners to the cap pieces *o* by a pivot or screw *v*, seen in fig. 1, and the rear corners are provided with journals r^1 that reach through the levers s^1. The latter are fixed to the rock shaft *t* which forms their fulcrum. The rear edge of the plate *p* drops in front of the heavy rib *x* on the bed *a*, as seen in fig. 2, and it thereby constitutes a solid backing to the breech bar *e*, to sustain that against the recoil of the explosion. The centre of the journals r^1 drops below that of the rock shaft *t* before the plate *p* rests on the ledge t^1, so that the levers s^1 act as diagonal braces to keep the plate *p* in its proper position during the discharge. The hammer *u* is pivoted to the plate *p* by means of the screw k^1, which passes through the bracket v^1 and through the cam-shaped portion of the hammer into the plate, and as the rear edge of the plate *p* is raised by the movement of the levers s^1, the head p_1 of the hammer is thrown back from the cone by the upper corner of the bar *e* striking the cam face u^1 of the hammer to the right of the line of its axis, the latter being so arranged as to cause the said cam face to just touch the bar when the head p^1 is against the cone f^1, and by this construction and relative arrangement of the hammer with the breech bar the possibility of a premature discharge of the battery is entirely prevented, because the head p_1 cannot touch the cap until the backing plate *p* is down to its place. The hammer is operated by a lanyard in the ordinary way. There is a thin metallic rack or guide *w*, figs. 2 and 3, placed between the sliding or breech bar *e* and the bed *a*; the front and rear edges are turned up, as seen in fig. 4, the front edge being scalloped on the line of each barrel, and the distance between the two edges should be equal to about one-half the length of the cartridge cases added to the width of the bar *e*, and this rack *w* is moved by a lip under the front edge of the plate *p*. By making the guide of such a width, it only traverses about one-half as far as the bar *e*, which leaves the scalloped front edge between the ends of the barrels and the bar when the latter is withdrawn. The cartridge holder or clamp *d* is composed of two wings made of thin sheet metal and hinged together. The openings l_1 through the wings are made to receive the cases *g*, and retain the said cases by the flanges m_1, which are clasped between the wings of the clamp *d* when closed, whereby the cartridges may be moved about, as when being transferred from the caisson to the batteries, &c., without danger of being misplaced or lost. The cartridge cases are composed of a thin metallic cylinder *g*; one end is closed by a solid metallic head h^1, the outside of which is made spherical, to fit against the cavity in the bar *e*, and allows the barrels *b* to be diverged, without impairing the joint between the cartridge head and the bar *e*, which is a very important feature. The head h^1 is encircled by a projecting flange m_1. The cylindrical portion of the head is made to fit snugly into the case *g*, and is bored out about in form of a parabola, thus

MOULD'S IMPROVEMENTS IN FOLDING AND MEASURING FABRICS.





leaving a thin edge against the case *g*, and these heads may be soldered in. The object of making the head so heavy is to give proper strength to that portion of the cartridge case necessarily intervening between the end of the barrels *b* and the breech bar *e*, which space is occupied by the clamp *d* and the scalloped rest or guide *w*. These cases may be loaded with patched bullets, and a wad also, if desired, saturated with grease, which allows any number of discharges without stopping to clear the barrels. A quantity of holders or clamps *d* are supplied with charged cartridges, and placed in suitable caissons for transportation. There is a sight d_1 fixed to the centre barrel, and there may be another attached to the rear of the bed *a* in the centre, as at s^1.

The whole battery is designed to be placed upon a light field carriage, and to be provided with an elevating screw *s* similar to ordnance.

Summary of the operation.—The levers s_1 are thrown back, placing the plate *p* in the position indicated in fig. 4, which also draws back the breech bar *e*, and leaves the scalloped edge of *w* between the rear end of the barrels and the bar *e*. A clamp containing the cartridges is then placed between the breech bar and the barrels, the cartridges resting in and being guided by the said scallops, and the levers s^1 are thrown forward, which forces the cartridges into their respective barrels. Either of these movements, that is, forward and back of the plate *p*, would force the hammer *u* away from the cone, so that the cap may be placed upon it without any further preparatory adjustment of the hammer, and the battery can be fired at will. After the discharge, the levers s^1 are again thrown back, which by the plate *w* withdraws the empty cartridge cases, when they may be removed, and another set supplied as before.

MOULD'S IMPROVEMENTS IN FOLDING AND MEASURING FABRICS.

Letters Patent have been granted to Mr. William Mould, of Belmont, near Bolton, for improvements in apparatus for folding and measuring fabrics.

These improvements consist in having two swinging concave blades or knives placed above a reciprocating table in the form of a segment of a circle, such table being supported in a suitable framework, and allowed to yield or fall, the yielding being obtained by means of a vertical rod, to which the yielding segmental table is attached, such rod sliding through the axis of the segment, and supported by means of a strong elastic material passing around the axis of the segment, and underneath a transverse projection fixed to the lower end of such vertical supporter rod. On each side of the segmental table is a roller covered with india rubber, flannel, or other suitable material, and which may, if required, be actuated and caused to revolve in one direction by means of the cloth being forced beneath it, and retained in such position during each repetition of the folding blades by means of a ratchet wheel upon its end coming in contact with a pawl or catch.

Fig. 1 is a side elevation of the machine, showing the table and its elastic bearing upon which the fabric is folded, and the curved blades for placing the fabric beneath the rollers to retain the fabric in its position. Fig. 2 is a front view of the same.

In fig. 1 *a*, *a*, is the framing of the machine, and *b* the main driving shaft supported therein; *c*, *c*, is the vibrating or oscillating framing, within which the yielding table *d* (in the form of a segment of a circle), and supported separately by the framing c^1 is placed; the framing terminates at its lower extremity in the counterbalance weights *e*, *e*, and is mounted on the central shaft *f*, *f*, upon which it oscillates, the elastic endless band *g* passes round the said shaft, and also round the rod or bar *h* attached to the vertical bars c^1, by this means a constant upward and yielding pressure is imparted to the table to retain the fabric in contact with the rollers *m*, *m*, during its folding. The blades *i*, *i*, are secured to the rods *k*, *k*, and are kept by means of the fingers and studs *l*, in the required position to place the fabric between the table and rollers *m*, *m*, which are covered with india rubber, the said rods *k*, *k*, being attached to the beams *n*, *n*, which are caused to vibrate on a centre in a contrary direction to the table by means of the bell-crank lever *o* and connecting rods *p*, *p*, from the crank on the main driving shaft *b*, the oscillation of the blades being nearly uniform. The strap *g* extends from one end of the yielding table to the other, passing beneath the rod *h*, and is pressed alternately by the bowls or rollers *r*, *r*, so as to depress the ends of the table, and ease the cloth from the pressure of the rollers *m*, *m*, whilst the blade is placing the next fold beneath them, the bowls *r*, *r*, being secured upon the sliding rod *s*, actuated by the cam *t*, and driven by the spur gearing *w*.

In order that the action of the several parts may be readily understood, suppose the machine is just commencing to fold or plait the fabric, the yielding table and framing is caused to oscillate by the crank and connecting rod, or other suitable mechanical arrangement, at the same time and identical with each oscillation, the swinging concave blades are brought into contact with the fabric to be folded, which passes over the guide board *u*, the blades forcing with each oscillation the fabric beneath the rollers, giving at the same time a slight turn to such rollers as are covered with india rubber, or to which a small ratchet wheel is fixed, preventing, by means of a pawl or catch, any backward movement to the rollers, at the same time causing the fabric to be firmly retained between the rollers and yielding segmental table, and forming thereby one complete fold during each oscillation, and so repeating such oscillation until the whole piece is folded, an index for measuring the length of the folded fabric being applied to the machine and worked by the rack and pinion *v*, as shown.

INSTITUTION OF MECHANICAL ENGINEERS.

The four days' proceedings of the Liverpool meeting were brought to a termination on Friday last. Soon after ten o'clock in the morning a special train, provided gratuitously by the London and North-Western Railway Company, left Lime-street Station for Parkside, 17 miles from Liverpool, and about 14½ from Manchester. At this place Mr. Ramsbottom, the talented principal engineer to the company, exhibited in action the water trough for filling tenders in motion. There is a long trough for the up and another for the down line, each a quarter of a mile in length, between the rails, and when a train proceeds at a rate of 22 miles an hour and upwards, the water is forced up a tube into the tender without the necessity of stopping—a great desideratum in the case of goods and other through trains where there is much traffic. From Parkside the members of the Institute went to Crewe to inspect the very extensive locomotive and rail works of the London and North-Western Railway Company. The rail works were the first visited, and here was exhibited the rolling of a number of Bessemer steel rails; in fact, the whole process, from the manufacture of the steel ingot to the completion of the finished rail, all done with extraordinary rapidity. Mr. Bessemer was present, and accompanied the party through the works. A substantial luncheon was served in the large hall of the Mechanics' Institute. Mr. Ramsbottom presided, and fully ensured the comfort of his numerous guests. After the repast, Mr Robertson, a gentleman of eminence in mechani engineering, proposed the health of Mr. Ra bottom, with whom he had worked in life with the hammer and chisel, as had many present been employed, and whom he remem becoming the Superintendent of that little li Manchester and Stockport Railway, the com ment of the Manchester and Birmingham li developed into the Great London and Western system, the extensive works of w visited he superintended with such rare Mr. Ramsbottom responded in a mode and then the party resumed their inspec whole of the works were viewed, in large smithy, the rolling mill, th fitting shops, the axle case-hardenin smithy, the frame-shotting machi scouring and wheel-turning d erecting shop, and the shop

grinding. The most recent improvements in the multifarious machinery in busy operation were explained by Mr. Ramsbottom and Mr. Webb, his principal assistant. The talented Superintendent's patent safety valve was exhibited, and the new travelling cranes, also that gentleman's invention. These latter, of course moved by steam, carried about an engine weighing nearly 30 tons, either transversely or longitudinally, and raised and lowered it as easily as though the ponderous mass were a bunch of grapes. Some smaller steam cranes were also shown, running on a single rail. On the completion of the inspection, those members of the Institute going southwards availed themselves of the ordinary train. Later on, the special train returned to Liverpool, where the rest of the party separated. The party visiting this town expressed their acknowledgments to Colonel Clay, the President, Mr. W. Stubbs, C.E., the Honorary Secretary, and the members of the Local Committee, for the arrangements made, in conjunction with the General Committee, for the congress now terminated. It was admitted on all hands that the Liverpool meeting has been one of the most interesting of the many held annually since the formation of the association, which numbers among its members many men famed for their mechanical genius. The place for the next year's provincial meeting has not yet been fixed. It will, however, take place somewhere in the North.

COATING ARMOUR PLATES.

The arrangement at the north end of the steam factory at Plymouth for the experimental coating of an armour-plate with copper is the greatest known attempt yet made in electro-metallurgy, and that it is being now made is due to the anxiety felt by the Controller of the Navy and the Admiralty to discover a means of preventing the oxidation from which iron-clad ships at present so severely suffer. Mr. Walam, of London, who is carrying out the experiments at Portsmouth, laid before the Controller plans for enamelling iron with brass or copper with the use of a little alkaline solution, the deposited metal to be of any specified thickness, brightness, or hardness. In accepting Mr. Walam's proposition, as an experiment copper was selected as the metal to deposit, and the arrangements are now so far complete that on Thursday week a trial plate, 15 ft. in length, was exhibited to the Lords of the Admiralty covered with a thin deposit of copper to show its nature. In one part of the building, where the apparatus is fixed, lay the armour-plate for coating, uncleaned and rough, just as it came from the drilling machines. It was 15ft. in length, 3ft. 5in. in width, and 4½ in. in thickness. Next to this huge piece of metal was a piece of iron plate suspended in slings. This had just been taken out of the "pickling" tank, and scrubbed with sand, all impurities being gone from the surface of the iron, which was then seen in all the clear lines of its grey fibre. A few feet from this cleansed plate was a plate of similar dimensions, but which had just been removed from the depositing tank, were it had been placed four hours. When removed, it was found to have received a really beautiful and bright hard coating of copper. These three plates thus illustrated the three stages—the uncleansed, the cleansed, and the electro-plated iron. The process of electro-coating by Mr. Walam's process, and the arrangements of his batteries and tanks, are as follows:—In the upper storey of the factory are erected the necessary batteries, in this instance composed of a series of five cells, containing a zinc surface of 720 sq. ft., and of copper of 1,500 sq. ft., the cells being charged with about 1,200 gallons of diluted sulphuric acid. From these batteries conductors—bands of copper 3 in. wide and half an inch thick—lead down to the depositing tank, which is 17 ft. long, 18 in. wide, and 5 ft. in height, and filled with a solution of cyanide of pottassium and tartrate of ammonia. This tank is of iron, and has an outer casing, which enables the solution to be heated by steam. The pickling or cleansing tank is nearly of the same dimensions, and is filled with a weak solution of sulphuric acid. The iron plate is placed in this tank first for a certain time, then taken out and scrubbed with sand, and afterwards placed in the depositing tank, the solution in which completes the cleansing process, and prevents the formation of any oxide between the bare iron and the deposited metal. The solution in the tank being heated next to 150 deg., the batteries are connected, and the copper is not only deposited upon the iron, but is driven into the open pores of the metal, and thus becomes a part of the plate itself, and forms an almost indestructible enamelled coating.—*Times.*

RAILWAY BREAKS.

We (*Liverpool Albion*) have been favoured with the opportunity of inspecting a very nicely constructed working-model of a railway train, consisting of 8 carriages and a locomotive-engine, working on a railway 30 ft. in length, constructed for the purpose of showing the application and efficacy of a newly-invented system of breaks, by which any number of carriages can be stopped almost immediately at whatever rate of speed it may have been running. Like most inventions of importance, this, which has been made by Mr. E. P. Houghton, of Seel-street, in this town, is marked by great simplicity in its arrangements and mode of working. He, in the first instance, insists that every carriage in a train, whatever number there may be, shall be furnished with a break to lock its wheels. The next, and a highly important feature in Mr. Houghton's invention, consists in the fact that all the breaks on all of the carriages shall be connected by connecting-rods, and held together by coupling-chains, similar to the coupling-chains which at present link the different portions of the train together. The connecting-rods are each furnished with a spiral spring in its central portion, by which all jerking or abrupt action is prevented in working the apparatus. Another important feature of this invention is, that the connecting-rods are allowed to move upwards or downwards to a considerable extent in a sort of slotted suspension hooks, so that ample provision is made for connecting carriages which differ in the height or diameter of their wheels; and further, that each individual break throughout the whole length of the train can be brought into immediate operation from either, or from both of the ends. This latter object is provided for by placing a shutting-lever in the guard's van at the fore-part, and another in the luggage-van at the after-part, the working of either of which by stopping the carriage to which it is immediately applied tightens the coupling-chains of the break connecting-rod in front of or behind it, as the case may be, and so applies the break of that carriage to its own wheels, which again in its turn checks the speed of the one next to it so rapidly as to be simultaneous all through the train, all shock or abruptness being effectually guarded against by the equalizing power of the spiral spring working on the central portion of the connecting-rods as already stated, and so on till all the carriages in the train are completely checked. The working of this very complete and efficacious system of break-application, as exhibited in the model, is, in every respect, most complete and satisfactory. The extent and rapidity of the checking-power, which is almost instantaneously obtained, it is difficult to believe without ocular proof; but the operation once witnessed, the conviction of its value and importance becomes fixed and irradicable. The plan recommends itself by its simplicity and the efficacy of its operation; while its value as a means of preventing accidents is at once perceptible to any one in the slightest degree acquainted with the principles which regulate mechanical action. This system of applying breaks to railway trains, which is exceedingly ingenious, has, we understand, been protected by patent, and has met with high approbation from gentlemen of eminence in the engineering world, to whom it has been submitted for inspection.

A NEW PORTABLE GAS FURNACE.

We have lately had an opportunity of witnessing the action of a new portable gas furnace, invented and patented by our townsman, Mr. W. Gore. As this furnace appears to us far to exceed anything that has previously been done in this direction, we cannot doubt that a description of it will prove interesting to our readers, to whom the invention is likely to be of more practical value than to any other community in the kingdom, and probably in the world.

The general features of the furnace are as follow:—It produces a "white heat" by means of ordinary coal gas and atmospheric air, without the help of bellows or tall chimney, and the melted substances are at all times perfectly accessible without chilling them or interfering with the action of the furnace; and if the crucible breaks the melted substances fall, without loss or injury, into a dish beneath. This is an important advantage to workers in gold and silver. The furnace is simple in construction, safe in use, portable, requires no brickwork erections, and may be used in any situation where gas is available. It is set in action simply by lighting and adjusting the gas, exactly as in an ordinary gas-lamp, and requires no further attention. It consists essentially of two open cylinders of fire-clay, one within the other, the outer one being much thicker and a little taller than the other; and a gas burner of very peculiar construction placed at the bottom of the interior cylinder. The crucible is supported inside the interior cylinder, near the top, by three projecting pegs of fire-clay forming part of that cylinder. The outer cylinder is covered by a moveable plate of fire-clay, which has a hole in its centre for the introduction of the crucible and materials, that hole being closed by a clay plug, with a small hole in it for stirring or examining the melted substances. The burner consists of an upright metallic tube, open at both ends, deeply corrugated at its upper end, so as to present the appearance of a star of numerous radiations, and the corrugations diminish gradually to nothing at about half the length of the burner downwards. Gas is admitted into the lower end of the burner by a common gas tap; it there mixes with a large quantity of air, and the mixture rises upwards; the flame commences at the top of the burner, and burns with great intensity within the inside cylinder to the height of the crucible; the heated products of combustion pass over the top edges of that cylinder, then downwards between the two cylinders, and into the chimney through a hole in the side of the outer cylinder near the bottom. The outer cylinder is enclosed within a sheet-iron casing, which has a chimney 6 ft. high attached to it, and is supported upon three iron legs, making the whole apparatus portable, and capable of being used either in a workshop or in the open air, as may be desirable. The various clay portions of the furnace may be used without injury to the action of the furnace until they are completely worn out, and the arrangement is such that they may then be replaced by new ones with perfect facility.

Several sizes of the furnace are manufactured. The first and smallest size consumes 33 cubic feet of gas (value seven farthings) per hour, and is suitable for assayers, jewellers, analytical chemists, experimentalists, dentists, and others. It is capable of fusing eight ounces of copper or six ounces of cast iron; copper begins to melt in it in about twelve minutes from the time of lighting. The second-sized one consumes about twice that quantity of gas, is suitable for manufacturing jewellers generally, and for a great variety of practical persons who require to melt small quantities of gold, silver, copper, german silver, brass, cast iron, glass, and other substances, or require a small crucible heated to high temperatures. It is capable of melting 45 ounces of copper, or 40 ounces of cast-iron, and with its heat up it melts one pound of copper in eight minutes; copper begins to melt in about twenty minutes from the time of lighting. We understand that a still larger size, estimated to fuse upwards of 500 ounces of copper is being constructed.—*Birmingham Post.*

SIMPLE LOCOMOTIVE ENGINES.

While visiting one of our engineering establishments lately, the superintendent pointed to a pile resembling a hay stack, covered with sail-cloth, and with a humorous twinkle of the eye said, "a big thing there." Lifting one end of the cover, he told us to take a look, which we did; but such a combination never before met our gaze. It was a steam-engine on wheels; and was provided with cog-wheels, sectors, bell-crank levers, and mechanical devices innumerable, packed as closely together as the works in a watch. Some men are "Jack of all trades; master of none;" and there are some machines designed to do an indescribable number of things, which are good for no *one* thing. This machine was one of those wonderful contrivances. It was intended to act as a common road engine, steam-plough, saw-mill, and several other things. But it was so complicated in arrangement as to be considered totally worthless for practical purposes; from the frequent leakages and disorder to which it was liable, and the difficulty of managing it properly. Simplicity of mechanism is one of the great aims of thoroughly practical common-sense engineers; and, above all other machines in the world, simplicity is most essential to a locomotive engine, either for rail or road. It is quite different from an engine that has a fixed position in a boat, or in a building; being subject to so many concussions and vicissitudes in moving itself. It should be constructed of as few parts as possible; in order to secure simplicity, lightness, and strength. The locomotives called "dummy engines," have been constructed to obviate a most senseless objection, which has been made to simple, common, high-pressure locomotives. The dummy is a condensing

gine, which in addition to all the parts of a common locomotive is provided with a condenser, ra pump, and other devices, involving extra ight and complex mechanism; simply to make mb the usual noise of the exhaust in the smoke e, while the engine is passing through streets. ery locomotive engineer knows that condensing gines are totally unfit for general railway purses. Depending upon condensing engines, we ver would have had our splendid railway system. e public in town and country should know that common, simple, high-pressure locomotive is er than horses or dummies, and is more easily ntrolled; and that the prejudice against its use on railways is worthy of the ignorance of the dark ages."—*Scientific American.*

TO CORRESPONDENTS.

Received.—W. & Co., T. N., W. B., C. F., E. F., L. & Co.

T. Parker.—The first paragraph of your letter ads strangely. You must alter it before we insert your communication.

T. B. (Stafford).—Neilson's first patent for the t blast was taken out in 1828.

C. F. J. Y.—We would insert your letter with easure did we believe it would aid the cause you lvocate. We believe that you must admit that the ibject has been handled by us with the greatest ipartiality; and were we to insert your letter, we ould be compelled to add a paragraph to justify ir statements, which might perhaps injure your se in a way which we would regret.

THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—Would you, in your next publication, kindly iform me when and where the first *tramway* was id down in England. I mean a road with iron ils for the conveyance of heavy goods, drawn by orse, or other power (not steam), and oblige yours uly, Wm. Hall.

[We very much doubt that there is any reliable iformation on this subject in existence. The uestion is a very interesting one, perhaps some of ur correspondents can supply the answer.—D. M. M.]

Miscellanea.

Rotterdam letters mention that a sample of otton from a new source is about to be offered in hat market on Saturday next. It consists of nine ales from the islands of Java, four of which were grown from New Orleans seed and five from East Indian. The quality of the former is stated to be very satisfactory, being not inferior as regards leanness to middling fair North American, while the report is also favourable with regard to staple and strength. The sample grown from the East Indian seed is not equal in the latter respects to that grown from New Orleans.

We learn from New York that the great ocean iron-clads "Dictator" and "Puritan" have at last assumed the shape of complete vessels, and it is hardly exaggeration to say that they surpass any craft ever built there. The hulls are now almost finished, the sides being made with a more formidable armour than those of any other vessels. The turrets will be of immense magnitude, no less than 2 ft. of iron being laid on with the usual wooden backing, in the most improved fashion. These vessels are to be 320 ft. long, 50 ft. wide, and will have 20 ft. depth of hold. Their engines are to have each two upright cylinders of 100 in. diameter, and 4 ft. stroke of piston. Their screws will be 21 ft. 6 in. in diameter, pitch 32 ft. Their boilers are six in number, three on each side, and are of return tubular pattern. They are expected to make 20 miles an hour. Their bows are as sharp, it is said, as a needle.

The "Scotia," belonging to the British and North American Royal Mail Ship Company, on her last voyage to New York, made the most extraordinarily fast run on record. She left Liverpool on the 18th of July, and made the passage to New York in nine days, two hours, and 15 minutes, beating the fastest passage previously made by nine hours and 45 minutes. The two quickest passages previously made were by the "Persia," in nine days, 12 hours, and 10 minutes, from Liverpool to New York; and the "Baltic," in nine days 12 hours.

A new war vessel is in course of construction at Cincinnati. This strange craft is known as "Elliott's War Turtle." It is shaped like a large punch-bowl, with the propeller in the form of a turbine wheel, placed at the bottom, and so arranged as to take water in through eight radial tubes, which may be opened or closed by valves, the said tubes connecting with the propeller and outer edge or hull of the vessel. The propeller passes the water downward from its cylinder, and revolves always in the same direction, and when the vessel is to be moved forward in any direction, one or more of the valves is opened, thereby relieving the pressure on that side, while the pressure still remains on the opposite side to propel the vessel. The turret is very similar in appearance to those on the "Monitors," but is built fixedly and firmly on the top of the vessel, and lined inside with heavy timber. It revolves with the boat by the action of the water upon the rudders placed in the mouth of the radial tubes. It mounts four guns.

A large quantity of land belonging to the Mersey Dock Board, at the north reserve, Birkenhead, will soon be brought into operation for shipbuilding purposes. This is a fortunate circumstance for the Dock Trust, inasmuch as the land has, up to the present time, been producing no income; and for Wallasey and Birkenhead, because it will draw 2,500 or 3,000 additional workmen to the Cheshire side. There is a prospect of the north reserve, Birkenhead, being almost exclusively devoted to shipbuilding yards, and the Dock Board will soon commence operations to reclaim a portion of the land, which is rendered unavailable at present by the water which washes over it.

An agricultural exhibition is to be held at Calcutta in January, 1864, under the direction of the Government, with the assistance and co-operation of the Agricultural and Horticultural Society of India. The object of the exhibition is to bring together for show, competition, and eventual sale, cattle and other live stock, agricultural implements and machinery, and articles of Indian agricultural produce. The machinery will comprise cultivators, ploughs, harrows, thrashing machines, saw mills, oil mills, pumps for irrigation, cotton-cleaning machines, and other implements. The exhibition will be held on the grounds adjoining the Lieutenant-Governor's House, at Belvidere, 35 acres in extent. It will commence on Monday, the 18th January, and will end on Saturday, the 23rd. No charge will be made for the admission of live stock and articles intended for exhibition. All produce and implements for show must arrive in Calcutta and be sent to the exhibition on or before the 31st of December, 1863, and live stock on or before the 14th of January, 1864. All live stock and articles exhibited and intended for sale must have their prices attached to them. A list of the prizes to be awarded may be seen at the offices of the Cotton Supply Association in Manchester, and the names of the parties through whom consignments may be made can also be obtained at the same place.

As a result of the recent meeting at Worcester of the Royal Agricultural Society, a public meeting was held in that city on Saturday last, "for the purpose of discussing the subject of steam cultivation, and, if so determined, to adopt measures for providing steam cultivation, and applying the same to land at an acreage cost." The chair was taken by Mr. E. Holland, M.P. A letter was read from the Right Hon. Sir J. S. Pakington (absent on the Continent), expressing himself favourable to the object of the meeting.—The chairman, in opening the proceedings, entered into the subject of steam cultivation, with which he is practically acquainted, having for some years adopted it on his own estate. He stated that experience of the effects of steam cultivation had proved that, on an average, there was an increase of produce by steam cultivation over the ordinary process to the extent of six or eight bushels an acre; besides which, the corn was superior in quality, and the land was permanently improved in value.—Lord Northwick moved the first resolution, "That as the successful application of steam power to the cultivation of the soil is now placed beyond doubt, and its value is universally admitted, means should be taken to secure its employment in this country."—This was seconded by Mr. H. F. Vernon, M.P., and carried.—Sir E. A. H. Lechmere moved, "That inasmuch as the cost of engines and tackle far exceeds the means of most farmers, it is desirable to establish a joint-stock company (limited), for the purpose of providing such implements by hire or purchase."—Mr. Lukin seconded this resolution, which was also carried unanimously.—Mr. T. G. Curtler then moved a resolution for raising a sum of £3,500, in shares of £1 each, and providing two sets of steam cultivators, with engines.—This also was carried.

A company is being formed in Paris called La Campagnie Generale des Chiffons de Paris. The object of this company appears to be to bring capital to the rescue of the waste substances that are cast idle in all our large cities, for want of patronage and attention requisite to make them useful in our industrial arts. The company propose to organize *les chiffoniers de Paris*, who number upwards of 25,000, and institute a demand for rags, bones, paper, broken glass, and other waste substances. From their extensive sphere of operations, it is contemplated that they will bring to light many tons of material which would otherwise be overlooked and neglected. The projectors of the company are sanguine of very excellent results, from the fruitful field they have before them. They hold out the very tempting prospect of a 25 per cent. dividend to the shareholders.

Some experiments with a new method for coating the iron plates of vessels, to preserve them from oxidation and fouling, have been found so satisfactory that the Admiralty have ordered the whole of the armour plates of the cupola ship "Royal Sovereign" to be thus covered. The material, which has been introduced by Messrs. H. J. Hall and Co., is termed "Brown's vitreous sheathing," and consists of a surface of glass fused upon small plates of iron, sufficiently thin to be to a certain extent flexible, which are applied to the ship by a new adhesive process, and which have been ascertained to be capable of resisting all ordinary contingencies from pressure or abrasion. Compared with other metallic coating substances, this sheating is economical, the cost being 1s. 6d. per square foot. The Peninsular and Oriental Company have tested the invention, and a trial of it has been ordered by the French Emperor at Cherbourg.

"A Practical Gunner," in a communication, says: —The first impression amongst naval and military men as to the manner in which the recent Parliamentary report on Armstrong ordnance is to be fully understood, is fully confirmed by the facts which have recently come to light; for the field-pieces which are therein stated to be a "success" have since had 14 in. cut off from their muzzles, a new coil added in front of the trunnions, new breech-screws and sights fitted, and the charge reduced to below that which is safely fired out of the Prussian field-pieces. With respect to the 40-pounders, a similar change will probably soon be made; for, although they have been gradually increased in weight, they are still too weak to stand the rough wear of actual service. The 110-pounders, when firing even 14 lb. of powder, were very inferior in penetration and damaging effect to the old smooth-bore 68-pounders; but now that the charge has to be reduced to 12 lb., the effect upon even the weakest description of armour would be *nil*. Besides this gun there are the earlier 110-pounders, which are still weaker. I can only fire 10 lb. of powder with the 110-pounder projectiles. Of these valuable weapons there are nearly 100, for which no use has yet been or is likely to be found. These, with the addition of the 20-pounders originally intended to fire 25-lb. projectiles, with a powder-charge of one-eighth their weight—but found too weak to do so—and some 9 and 6-pounders, constitute the whole of the present service Armstrong gun.

A number of interesting and highly important experiments with heavy pieces of ordnance are at present being conducted at the battery of Newhaven, on the coast of Sussex. The object of these experiments is understood to be to test the comparative utility of the smooth-bore and the rifled ordnance in penetrating earthworks, and they form a portion of the series of experiments lately commenced by the Select Ordnance Committee, which have been conducted at different places. The battery at Newhaven contains 8 guns, consisting of a 110 lb. Armstrong breech-loader, a 70 lb. side-wedge Armstrong breech-loader, a 40 lb., 20 lb., and 12 lb. Armstrong breech-loader, and 68 lb. and 32 lb. smooth-bore, and an 8-inch shell smooth-bore. The object fired at is an extensive earth-work which has been erected on the Castle-hill, at a range of 1,060 yards. A telegraphic wire has been laid down from the battery to the earth-work, so that instantaneous communication is maintained between the firing party and those at the butts. The guns are worked by a detachment of about 100 men of the Royal Artillery, from Dover, who are under the command of Captain Tottenham. The members of the Ordnance Committee in attendance are General St. George, R.A., president; Captain Heath, R.N., vice-president; Captain Noble, R.A., secretary; Colonel Gallwey, R.E., Colonel Lefroy, R.A., and Mr. Behenna, R.A. The experiments were commenced on Tuesday, and it is expected that they will extend over ten days or a fortnight.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

39. D. NEVIN and W. COPPIN. *Improvements in machinery for clearing and separating the woody parts from the fibrous portion of flax, hemp, or other like material.* Dated January 5, 1863.

For the purposes of this invention, two sets of revolving flat or curved bars are used, bolted or otherwise secured to arms keyed on to two separate parallel shafts revolving towards each other. The bars of one shaft enter between the bars of the other set, and are kept from contact by means of toothed wheels of equal diameters and equal number of teeth keyed on the two shafts working into each other. One or more of the bars of each set are provided with short teeth, for the purpose of keeping the fibre straight and clear. Above the revolving sets of bars is placed a cover having a rectangular opening through which to pass the fibrous material, and by the action of the bars both sides of the flax or other like material are cleared at the same time. An improved set of holders or clips for holding flax, hemp, or other like material while being dressed or cleaned is provided. Each holder or clip consists of two sets of bars or fluting faced or covered with india rubber or other like material, having a joint or hinge at one end; the two sides closing fit into each other, and are held together by the aid of springs and rack-work, one of these holders being placed or fastened on the end of the material to be dressed; the other end is passed through the opening in the cover of the machine, and dressed between the revolving sets of bars, and when sufficiently acted on is withdrawn, and the dressed end is secured in another clip or holder, the first then being removed by the undressed end, passed through the opening, and dressed in like manner. *Patent completed.*

40. J. A. MUNN and J. D. COBB. *Improvements in automatic walking dolls and other figures.* (A communication.) Dated January 6, 1863.

This invention consists in such a construction and combination of parts that the figures stand upright, and move forward in a manner resembling that of a biped or quadruped in walking. The propelling power of these figures is obtained by the use of a spring acting through gearing upon a horizontal cross shaft, near the bottom of the frame, and supporting the said gearing. *Patent abandoned.*

41. W. E. NEWTON. *Improvements in magneto-electric telegraphs.* (A communication.) Dated January 6, 1863.

The leading object of this invention is to enable the operator by the operation or movement which he makes to designate or select the character or sign which he desires to transmit to develop the electric current by which such character or sign is transmitted. The invention consists in the employment of a magneto-electric engine, by the rotation of which electric impulses are induced alternately in opposite directions. The electro-magnetic engine is connected by suitable conductors with electro-magnets, the polarity of which is alternately reversed by the alternately reversed impulses induced by the engine. An interposed vibrating permanent magnet or armature at the end of a pendulous lever is, by the alternately reversed polarity of the electro-magnets, when these are combined, caused to vibrate, and by means of pallets and arms at the opposite end of the lever, will actuate an escapement wheel, on the axle of which is an index or pointer which is made to traverse round and indicate on a circular series of letters, signs, or figures, the particular sign it is desired to transmit to the distant station. This part of the apparatus is connected with a mechanism which, as the operator indicates or designates the characters or signs which he desires to transmit, will set the magneto-electric engine in action, and will thereby develop or generate the electric impulses which will transmit such character or sign. The second part of the invention consists in combining with the electro-magnetic apparatus, or the equivalent thereof, the escapement arrangement above mentioned, whereby to indicate or develop the character or sign transmitted. *Patent completed.*

42. C. T. JUDKINS. *New alloys.* (A communication.) Dated January 6, 1863.

The object of this invention is the production of alloys which may be variously and advantageously used in the arts, some of which are of use in the place of composition or the alloy commonly used for bearings in machinery, others particularly valuable for gun metal, others from their colour, texture, and lustre peculiarly well adapted for use as substitutes for gold in the manufacture of watch cases, chains, and ornamental jewellery, while others are applicable for various uses, as in springs, sheet metal, wire, sheathing, &c. The invention consists in combining copper and aluminium, or an alloy of these metals, with one or more light coloured metals within the limits of the proportions herein specified, the variations within the said limits being made for the purpose of producing certain desirable qualities in the alloys resulting from the said combination, so as best to adapt them for specific purposes. *Patent completed.*

43. J. ECKERSLEY. *Improvements in the manufacture and spinning of silk, in cutting pile fabrics, and in weaving fibrous materials.* Dated January 6, 1863.

This invention is not described apart from the drawings. *Patent completed.*

44. J. LEIGH. *Improvements in the treatment of gas produced by the distillation of coal, cannel, bituminous shale, boghead, mineral oils, petroleum, or other combustible substances, and for the obtaining certain products therefrom.* Dated January 6, 1863.

This invention consists in the subjection of the gas that is obtained in the distillation of coal, cannel, bituminous shale, boghead, mineral oils, petroleum, or other combustible substances to the action of nitric acid, or of a mixture of nitric and sulphuric acids, by which nitrobenzole and certain other compounds are obtained, and in the course of which certain substances are removed from the gas employed. *Patent completed.*

45. T. VICARS and T. VICARS, jun., and T. ASHMORE. *Improvements in machinery for manufacturing bread, biscuits, and other like articles.* Dated January 6, 1863.

This invention relates to improved machinery or machines to be employed for mixing together materials into a dough or paste to be afterwards made and shaped into loaves, biscuits, and other such like articles. One of such machines consists of a framing carrying two upright shafts on which knives or beaters are fitted or disposed in a helical or spiral direction, the said shafts receiving rotary motion through the agency of bevelled and spur gearing. There is a table or platform connected to the framing, and on the platform there is placed a moveable trough or vessel containing the materials to be mixed together. The platform and trough thereon can be either raised and lowered, or have horizontal rotary motion imparted thereto, either in connection with, or independent of, the vertical rotating shafts and bevelled gearing before mentioned, during the time of mixing the said materials together into a dough or paste to be afterwards shaped as before stated. The other mixing machine above referred to consists of a trough supported by a suitable framing; this trough, which may be either fixed or moveable, is furnished with a shaft revolving horizontally therein; and around this shaft a system of knives or beaters is fixed and disposed in a helical or spiral direction, motion being imparted to the aforesaid shaft and knives or beaters thereon, so as to mix and incorporate the materials placed in the trough into a dough or paste to be afterwards shaped into loaves, biscuits, or other like articles. *Patent abandoned.*

46. J. A. KNIGHT. *Improvements in printing presses.* (A communication.) Dated January 6, 1863.

These improvements chiefly relate to hand presses for printing circulars and other small sheets. The frame of the machine consists of two parallel guide ways in which the bed of the press slides, properly secured together and elevated to any convenient height. At the bottom of this guide way or sides of the frame, about equidistant from the ends, are the bearings of the driving shaft. On this shaft is fixed a gear wheel which works into a ratchet formed on the under side of the bed-plate. By turning the shaft in opposite directions, the desired movements of the bed supporting the form is obtained. Above the shaft an ordinary compression roller is placed. The tympan of the machine is made self-acting by means of a dog or curved piece fixed on the end of said tympan, and acting against a fixed cam on the end of the frame to bring it down upon the form before it comes to the roller, and by a spring to throw it open as soon as it is clear of the roller on either side. When the tympan is brought back, the roller depresses it to make the impression on the sheet. The type is inked and sheet laid on and delivered on each side the roller. The machine may be made self-inking by means of a roller carried by a bent bar, and operated in any convenient manner, but in practice it is found more economical to apply the ink to the press with a hand roller. *Patent abandoned.*

47. M. HODGART. *Improvements in presses for pressing cotton and other substances.* (A communication.) Dated January 6, 1863.

This invention is not described apart from the drawings. *Patent completed.*

48. E. V. GARDNER. *Improvements in the treatment of petroleum and mineral oils, and in apparatus employed therein.* Dated January 6, 1863.

The first part of this invention relates to arrangements of certain apparatus, and to the use of both high and low pressure and superheated steam in connection therewith, by which means the patentee completely obviates all risk of fire and explosion, and contrives to separate the various distinct compounds which are contained in ordinary mineral oils in one continuous operation. The second part of the invention consists of an improved agitator to be used in the purification of these oils. The third part of the invention consists of an apparatus or still used in the rectification of the oils; the fourth part, to certain chemical processes, by means of which he is able greatly to increase the oil and diminish the tarry or heavy carbonaceous products, and to render the various oils free from their unpleasant odour. *Patent completed.*

49. J. G. DAHLKE. *Improvements in machinery for cutting clay in the manufacture of bricks, tiles, and similar articles.* (A communication.) Dated January 6, 1863.

This invention consists in mounting upon a frame with wheels for travelling on rails or trams a set of rollers covered by an endless belt, which belt receives the clay from another set of rollers, on to which it is expressed from a moulding machine. At the further end of the rollers other rollers are fixed, and over them a frame capable of transverse motion; between the endless belt and transverse frame a cutting wire or blade is placed, and the far end of the transverse frame is provided with a door, which usually remains closed, but which may be opened when required. The endless belt rollers and the transverse frame are all connected to the wheeled frame, and are capable of being moved to and fro. On the clay being fed from the moulding machine it travels along the endless belt, and its outer end abuts against the door before mentioned. The cutter is then brought into action and severs the clay between the endless belt and that contained in the transverse frame. Then the transverse frame is pulled out laterally, whereby the clay is brought into contact with, say three, cutting wires or blades, and the three portions of clay so cut, say bricks, are removed ready for being stacked. In being pulled out, the frame falls, and the clay, still continuing to issue from the moulding machine, is received on the rollers over which the transverse frame has been drawn. On the frame being returned to its original position, it rises over the rollers, receives the fresh charge, which is severed as before, when the frame is again pulled out, and so on. It will be understood that the block of clay drawn out by the transverse frame may be divided into any desired number of parts, according to the number of cutting wires to which it is exposed in its lateral travel. *Patent completed.*

50. G. TURNER. *Making leather from waste pieces of leather.* Dated January 6, 1863.

In carrying out this invention, leather cuttings or parings, or other waste pieces of leather or skin, are first converted into pulp by any of the processes already known. This pulp—which may then be washed or left unwashed—is thereupon digested in warm water in suitable vessels. When it is sufficiently digested, the pulp is treated with a caustic alkaline solution, such as is formed by the oxides of alkaline metals, the alkaline earths, the hydrates of such oxides, the subcarbonates of these, or other substances having an alkaline reaction. If desired, animal or vegetable gelatinous matter may be added to, and digested with, the pulp. After the pulp, with or without the addition of animal or vegetable gelatinous matter, has been treated with the caustic alkaline solution, it is pressed or rolled into sheets or bands of the desirable thickness. These sheets or bands are then immersed in tan liquor, or other acid astringent solution, which arrests the action of the alkali, combines with the organic matter dissolved by the alkali, and converts the gelatinous matter into tannate of gelatine. *Patent completed.*

51. J. WHITWORTH and W. W. HULSE. *Improvements in ordnance.* Dated January 6, 1863.

This invention consists in the employment of an improved method of manufacturing ordnance made of what is now termed homogeneous metal, or mild steel or steel iron, or other similar material. The patentees cast an ingot with a hole through it, and afterwards hammer it between an angular-shaped anvil block and a hammer head of a similar or a flat shape. A mandril of a taper form is inserted through the hole cast in the ingot, and the operation of hammering or forging proceeds till the mandril becomes too hot from its contact with the heated metal of the ingot; it is then withdrawn, and a cold mandril is inserted in the place of the heated one, and the hammering or forging is continued until it is made of the desired size and shape. If preferred, a hollow mandril may be used and cooled alternately. The hammered tubular ingot is subsequently annealed. If necessary, the interior surface of the tubular ingot may be converted to the required depth. For heavy guns for ships and fortifications, constructed on what is termed the built-up system, they make the inner tube from a tubular ingot, and strengthen the inner tube with cylinders made of homogeneous metal, as above described, and put on by hydraulic pressure or other suitable means in one or more series as required. For closing the breech of these built-up guns they employ a breech on which screws of two or more different diameters are cut. The screw with the smallest diameter takes into an interior screw in the breech end of the inner tube, and the screws of the larger diameters take at the same time into interior screws made in the second, or second and other series of hoops. *Patent completed.*

52. J. H. JOHNSON. *Improvements in rocket torpedoes, and in the apparatus for directing the flight of the same under water.* (A communication.) Dated January 6, 1863.

This invention relates to a peculiar construction and arrangement of rocket torpedoes, and to improvements in the apparatus employed in directing their flight under water. According to this invention, it is proposed to apply hinged guiding or steering wings to the rear end of the torpedo, which will open out or expand by the action of the gases issuing from the rear end of the torpedo, and so be brought to act upon the resisting body of water, in place of being fixed and situate in the line of the issuing gases, where the resistance required for effecting the steerage is nil, by reason of the gases displacing the water at that part. Springs may be substituted for hinges in attaching the wings if preferred. The rear part of the torpedo—the case of which is of metal—is filled with rocket composition, whilst the front chamber is charged with gunpowder, or other explosive material. This charge is exploded either by the burning out of the rocket composition, or by means of

ny convenient percussion fuse arrangement, which will nsure the firing of the explosive charge the instant the orpedo strikes a resisting object. The means employed for irecting the flight of these or other rocket torpedoes conist of a tube passing through the side of a vessel or fort, nd dipping down into the water some distance below the urface. This tube is passed through a ball and socket, or ther form of universal joint, contained in the side of the essel or fort, and is provided with suitable blocks and ackle for drawing it in or out of the joint, or for adjusting ts angle either vertically or horizontally. *Patent abandoned.*

53. J. Neale. *Improvements in the manufacture of capsules.* (A communication.) Dated January 7, 1863.

This invention consists in combining with a disc made of wood, glass, porcelain, or other suitable material, which may be embossed or otherwise ornamented, a piece of flexible metal, similar to that ordinarily employed in making metallic capsules, which metal—instead of being cut into discs and worked up into a shape resembling a thimble—is first cut out by discs or other suitable means into, or shaped somewhat resembling, a lady's collar, and is then, at a point near the narrowest part of such piece, wrapped round the disc, and by the use of a cord or other pressure, the flexible metal is forced into a groove or indentation formed on the edge of the embossed or ornamented disc. These capsules may be affixed or fastened to the bottles or jars by the ordinary means used for applying metallic capsules. *Patent abandoned.*

54. T. F. Cashin. *Improvements in covering wire, crinoline steel, or hoops for skirts.* Dated January 7, 1863.

It is proposed, according to this invention, in covering wire, crinoline steel, or other article intended for the purpose of stiffening skirts, to apply paper or cloth paper, that is, cloth faced with paper pulp, of sufficient width to cover both the sides and edges and overlap; paste or other adhesive preparation is used to fasten the paper on the steel or other materials, around which it may be simply lapped and folded, or wound around by machinery, or may be drawn upon it between dies and pulleys. Steel wire or metallic bands when necessary are covered with lacker composed with naphtha and gum, or other suitable composition, to prevent corrosion. When covered, the bands or strips of whatever length are subjected to a process of drying by the application of heated irons or rolls, and may be glazed and have a pattern printed thereon; or they may be embossed with sunk or raised patterns, or impressed with appropriate devices and edgings; coloured paper or cloth paper, plain or ornamental, may also be used, or colour may be applied when the article is covered. *Patent abandoned.*

55. W. Cartree and J. Crowther. *An improved mode of perching and dressing textile fabrics during the process of weaving.* Dated January 7, 1863.

This invention is carried out as follows:—Immediately under the breast beam of the loom the inventors place a roller which extends across the loom. The surface of this roller is covered with card cloth, teazles, or other material usually employed for the purpose of raising and cleansing the surface or face of textile fabrics. The pivots of this roller work in adjustable bearings, so that the surface of the roller can be brought into contact (with more or less pressure) with the face side of the fabric which is being woven in the loom. The roller when at work turns round on its axis (with more or less velocity as may be required) by means of a band or strap, or toothed gearing, which communicates motion to it from one or other of the other motions of the loom. By this means the card cloth or other material perches and dresses the textile fabric at the same time that it is being woven or produced in the loom. *Patent abandoned.*

56. W. S. Bruce. *Improvements in lucifer matches, fusees, and other similar lights, and in the boxes or holders for containing the same.* (A communication.) Dated January 7, 1863.

These matches are so prepared that, when lighted, they burn with a flame at one end, and with sparks only at the other, being thus adapted for the various uses of the common match, and at the same time also adapted to the purpose of a cigar or pipe light. The match may be prepared to light at either or both ends. The improved boxes or holders may be made in various ways, and of different materials, chiefly, however, of reeds, or other hollow ligneous substances, veneer wood, natural cork, or any other suitable material, tinted, painted, varnished, stamped, or otherwise ornamented, according to fancy, with different colours and designs, and may also be covered with coloured or other paper, so as to present when finished a neat and compact appearance. *Patent abandoned.*

57. T. Storey. *Improvements in compound waterproof and ornamental fabrics, applicable to various purposes.* Dated Janury 7, 1863.

This invention consists in the manufacture of compound waterproof and ornamental fabrics, applicable for covering and various other purposes, by taking a woven fabric of cotton or other suitable fibrous material, and coating it with one or more coats of oil, oxidized oil, india rubber, or other similar substances or compositions possessing adhesive and water-repellent properties, and then covering the adhesive surface with flock material dyed of any required colour; and, lastly, consolidating or embossing the surface of the flock material with any suitable design. *Patent abandoned.*

58. W. Clark. *Improved media for advertising.* (A communication.) Dated January 7, 1863.

For the purposes of this invention, the inventor makes use of plates, dishes, glasses, and other similar table requisites of dining or coffee rooms, and all public establishments in general, for the supply of drinks and eatables. For example, he engraves, imprints, paints, or otherwise applies in any suitable manner on the plates, dishes, glasses, cups, saucers, and other objects, either plain or illustrated advertisements. *Patent abandoned.*

59. G. C. Grimes. *Improvements in means or apparatus for treating splints used in the manufacture of matches and other lights.* Dated January 7, 1863.

These improvements relate—1, to what is commonly called the clamp filling machine, and they consist in drawing the splints into the clamps from the boxes or holders in which they are placed to be tranferred to such clamps, in place of pushing the splints from such boxes or holders into the clamps, and in using sharp points to stick into the ends of the splints for drawing the splints into position in the clamp. The clamps are placed between the boxes or holders and the drawing means. 2, in place of the clamp boards of the clamping frame being separate and independent of each other, as is the common practice, the patentee connects them to bands or other suitable means adapted to admit of their being suspended at intervals apart from each other sufficient for the free passage of splints between any pair of them, and yet when splints are placed between them of their being pressed together to hold such splints tightly between them. *Patent completed.*

60. G. A. Huddart. *Improvements in buttons.* Dated January 7, 1863.

This invention is not described apart from the drawings. *Patent completed.*

61. J. Aveling. *Improvements in the construction of traction engines.* Dated January 7, 1863.

This invention is not described apart from the drawings. *Patent completed.*

62. G. Dowler. *Improvements in the manufacture of match boxes.* Dated January 7, 1863.

This invention consists in making match boxes with a double bottom or case to contain a supply of strikers or sheets of material, upon which the matches are ignited; this double bottom or case may be formed as a cap to fit on the bottom of the match box. The invention also consists in forming a frame on the bottom of a match box, which will allow the striker to be slipped in and out, so that, when one side of the striker is worn out, it may be reversed; this frame may be constructed to hold more than one striker. It will be best formed by bending up the lower edges of the sides and ends of the box to form grooves, into which grooves a thin metal frame is fitted, which will hold the striker and allow nearly all its surface to be exposed for use. For other forms of boxes this part will be best formed by making a flanged ring or cap to fit the bottom of the box, and which may fit over the false bottom already named. *Patent completed.*

63. G. T. Bousfield. *Improvements in skate fasteners.* (A communication.) Dated January 7, 1863.

This invention is not described apart from the drawings. *Patent completed.*

64. H. Harben. *Improvements in the manufacture of fibrous material for cleansing machinery and other purposes.* Dated January 7, 1863.

In carrying out this invention, the inventor uses zostera marina, or other aquatic weed, plant, or grass, either in a green or dried state, and either whole or in pieces. He steeps the plant in a solution of carbonate of soda, or chloride of lime, or any other alkali with water; when sufficiently steeped he passes it through rollers, or otherwise subjects it to pressure, subsequently to which he partially dries it by exposure to the air or artificial heat. When a sufficiency of the moisture is thus removed, he places it in a machine similar in principle to an ordinary butter churn, in which the plant is revolved, agitated, and beaten till it is sufficiently softened and separated longitudinally; the product is then fit for the purposes to which waste is applicable, and from its fibrous and absorbent qualities it is specially applicable to cleansing of machinery; for this purpose the whole of the plant is made available, and it is not necessary to extract the fibre only. *Patent abandoned.*

65. J. H. Johnson. *Improvements in the permanent way of railways.* (A communication.) Dated January 7, 1863.

This invention relates to certain improved constructions of sleepers employed in the permanent way of railways, and consists, according to the modification of the invention, in using lighter sleepers, whereby a considerable saving of timber is effected, whilst the proper stability of the way is retained by attaching on the upper surface at those parts where the rails rest, or the chairs are secured, and which are most liable to decay, extra blocks of oak or other durable wood of a sufficient length only to give a firm support to the rails. According to another modification, it is proposed to employ short blocks of timber of the ordinary section of sleepers for supporting the rails, or rails and chairs, and to connect these blocks by bars of iron, which bars form the intermediate portion of the sleeper between the rail-bearing surfaces. *Patent completed.*

66. R. Grogan. *New and improved propellers for vessels driven by steam or other power.* Dated January 8, 1863.

This invention consists of certain vanes or blades of a flat, spiral, or other suitable form, two or more of which are mounted upon or attached to shafts, cranks, or beams having either vertical or horizontal axes, and wholly or partially submerged at or in or partially within the sides, bottom, or stern of vessels, where the same (when fitted to the required mechanism of ordinary construction) can be made to act as paddles, or take the place of a screw propeller. *Patent abandoned.*

67. L. Hull. *Having reference to the treatment of ground caoutchouc, and for the purpose of rendering it elastic or improving its elasticity, as well as imparting to such caoutchouc other useful properties.* Dated January 8, 1863.

This invention consists in treating the ground caoutchouc with carbon, spirits, and chloride of sulphur. *Patent completed.*

68. A. Guild. *Improved machinery for breaking and cleaning flax, hemp, and other fibre-yielding plants.* (A communication.) Dated January 8, 1863.

This invention relates to a novel arrangement of drawing gear for operating the nipping rollers of machines intended to be employed in the breaking and cleaning of flax, hemp, and other fibre-yielding plants. In the class of machine to which the invention applies, the woody portions of the material under treatment are broken by passing under the crushing action of fixed fluted rollers, and the broken fragments are loosened from the fibres by a rubbing action obtained by driving the rollers alternately in opposite directions, but in such manner as to produce a progressive motion of the fabrics through the machine. The invention cannot be described without reference to the drawings. *Patent completed.*

69. C. Allen. *Improvements in apparatus for signalling on railways by detonating or explosive signals.* Dated January 8, 1863.

This invention has for its object the providing an improved, efficient, and simple apparatus for signalling by detonating or explosive signals, so that the same may be placed on or taken off the rail by acting on a suitable handle, or otherwise, placed at any convenient distance from the point at which it may be considered desirable to apply the said signals. *Patent completed.*

70. R. T. and R. Monteith. *Improvements in the manufacture of dyes from aniline and its analogues.* (A communication.) Dated January 8, 1863.

The patentees claim the production of red and violet colouring matters by the decomposition of hydrochlorate or sulphate of aniline, or its analogues, by heat, whether those substances are used by themselves or mixed with aniline or its analogues, and whether either of the above mixtures is heated alone, or after it has been mixed with sand or any other finely divided substance as aforesaid. Also the use of salts of ammonia for the purpose described. Also the admixture with the colouring substances (as described) of sand, gelatinous silicic acid, fluoride of calcium, or any other finely divided substances not liable to act otherwise than mechanically upon the substances employed in the process above described. And also the production of brown colours by the decomposition of salts of aniline, or its analogues, by heat, as above described. Whenever hydrochlorate of aniline or aniline is mentioned, the hydrochlorate of aniline of commerce or aniline of commerce is intended. *Patent completed.*

71. J. Punshon. *A balance cylinder with counter-pressure and valves connected therewith for stationary and locomotive steam engines, to prevent overwinding at collieries, to provide extra breakage power to locomotive steam engines, and whenever steam is the motive power to provide counter-pressure to stop instantly the action.* Dated January 9, 1863.

This invention is not described apart from the drawings. *Patent abandoned.*

72. C. Worssam. *An improved lithographic press.* Dated January 9, 1863.

This invention is not described apart from the drawings. *Patent completed.*

73. W. H. Tucker. *Improvements in locks and in the modes of connecting the knobs and spindles of the same.* Dated January 9, 1863.

This invention consists—1, in a mode of preventing the positions of the gatings in the levers or tumblers of locks being felt or ascertained by the aid of end pressure directed against the bolts of the said locks, and the patentee produces this effect by the use of a moveable lifting piece, so constructed and disposed in the lock that, if end pressure be directed against the bolt, the said piece will be so influenced by it that a pin or stump in it will lift or gather up the levers or tumblers in a mass, and thereby prevent their being acted on separately by picking instruments, so as to feel or ascertain the position of their gatings. 2, in modes of constructing and connecting the knobs, roses, and spindles of locks in such a manner that their requisite firmness of hold to the doors to which they are attached, and their ready and accurate adjustment to their varying thicknesses, shall be more effectively combined than has heretofore been the case. *Patent completed.*

74. R. Thomas. *Improvements in apparatus for rendering hair wavy.* Dated January 9, 1863.

This invention consists in constructing an apparatus so arranged that the hair to be acted upon is nipped or firmly held between two smooth corrugated or undulated surfaces of peculiar formation, the projections of one of which surfaces fit into the recesses of the other, and on being applied to the hair in a heated state impart to it their corrugated or undulated form. *Patent abandoned.*

75. C. E. Gray. *Improvements in wringing machines.* Dated January 9, 1863.

One form of construction consists of two galvanized iron brackets screwed to a piece of wood. The upper end of each of the said brackets has a vertical slot or opening formed through the same to receive the end of a short bent lever, the lever fitting loosely in a vertical groove in the bracket. The lower end of the bent lever may work either on a fixed fulcrum of the ordinary kind, or on a loose rolling fulcrum, which latter the patentee claims as new in the construction of wringing machines; or the top of the bent lever may work on a loose rolling fulcrum formed by the slot at top of the brackets aforesaid, and be provided with an elastic cushion for the end of the bent lever aforesaid to press against; or the elastic cushion may be adapted to the bracket in such a manner that the lower end of the bent lever may press against the same, and when this arrangement is used the top of the bent lever is not rigidly fixed to the slot in the top of the bracket. The two brackets and levers thus arranged respectively support the ends of the axes of spindles of two cylindrical rollers covered, by preference, with india rubber, the lower roller being supported by the brackets, and the upper roller by the bent levers aforesaid, a winch handle being fixed on the spindle of the lower roller for imparting rotary motion thereto, as usually practised. The upper roller moves outwards as the articles to be wrung or squeezed pass between the rollers, the elastic cushions causing sufficient pressure to express the liquid from the articles as they are passed between the said rollers. The above machine may be fixed to a tub or washing machine by any convenient means. *Patent completed.*

76. E. A. Goupil. *An improved locomotive apparatus called a "spherical wheel."* Dated January 9, 1863.

The object of this invention is the application of the sphere for moving furniture, to vehicles used to transport

cumbrous material, and to locomotion generally. One of the applications of the invention is as follows:—The inventor encloses a spherical ball of any dimension or material in a cavity or socket, the form of which will vary for ornament or solidity from a spherical to a spheroidal, or even a cylindrical shape, subject, however, to the invariable rule that the height of the socket shall be greater than the extent of the radius of the complete sphere, and that the orifice of the said socket be smaller than the diameter of the sphere, but sufficient to permit a segment of the inserted sphere (say about one-third) to project beyond the socket. It will be understood that the socket must bear vertically upon the summit of the sphere, so that the transmission of movement be rectilineal. The sphere being naturally moveable in every direction, one articulation or joint suffices, whereas, with the cylinder usually employed, two articulations are necessary, one vertical and one horizontal. The socket may be fitted to furniture in the same way as the castor it is intended to replace, and to other objects as may be found most convenient. *Patent abandoned.*

77. M. Cartwright. *Improvements in alarums for portable and stationary uses.* Dated January 9, 1863.

This alarum, according to the scale on which it is made, is intended to be worn in the pocket or to be fixed in any part of a building or otherwise. The inventor encloses the alarum in a case, or not, as required. It consists of a spring made to act through wheelwork upon a ratchet wheel, which drives a double ratchet, on the shaft of which one or more hammers is or are mounted, all held between plates or in a suitable frame. There are as many bells as hammers, and on the spring being wound up the hammers are made to oscillate and strike the bells, no matter in what position the alarum is held. He provides a stop pin, which gears into the ratchet wheel and stops the working of the apparatus after the spring is wound up, until it is released from the wheel, and this is done by simply pulling it. *Patent abandoned.*

78. D. B. Parsons. *Improvements in reaping and mowing machines.* (A communication.) Dated January 9, 1863.

We cannot here give space to the details of this invention. *Patent abandoned.*

79. E. T. Hughes. *Improvements in machinerg or apparatus for printing or staining woven fabrics, warps, paper, and other articles.* (A communication.) Dated January 9, 1863.

This invention consists of a suitable frame of iron or other metal, the sides of which are connected by tie rods and bolts to keep it firm and prevent the sides giving way with the pressure or operation. Between the right and left side of the frame there is a tie piece, and on the left side a trundle shaft or cylinder, with pins to scratch the desired pattern or design, and also projecting pieces to keep the material to its full width. For some patterns the cylinder turns its full circumference, and for others only one-half, the pins being regulated by a lever which slides up and down, and has attached to it a handle. A table, on which the material to be operated on rests, slides in grooves, and is moved on rollers with conical keys, or blocks and screws, by which are regulated the pads or cushions attached to the cylinders for the purpose of giving the requisite pressure on the material which receives the pattern or design. The said table is covered with woollen cloth, or other suitable material, over which is an oil or waxed cloth, the two cloths being kept in their proper place by a comb on the right-hand side of the table, and on the left-hand side a wooden roller, which is also provided with a comb and ratchet to keep the cloth at full stretch. The table is also recessed at its sides, in order to receive the edges of the cloths, and thus regulate the tension of them as required. On the sides of the table are six small rollers, three on each side, to receive the frame when the impression is being taken, shafts or spindles being attached to the frame at each end, which are also provided with rollers with a base to maintain the frame in its proper place, and stop pieces to arrest its motion when necessary. The said frame has conical bearings to receive the moveable table on which the material to be printed or stained is spread, and is prevented moving in the direction of its breadth by the rollers, the frame which holds the rollers being immoveable. On the frame is also fixed a fabric to serve as a lining and prevent stains on the materials being printed. On an indicator is placed a plate, which is turned by a shaft and handle above the framing, and also two pulleys which turn one to the right and the other to the left, by means of bands or gearing, for the purpose of moving the carriage backwards and forwards, which carries the feeder to supply the necessary colouring matter to give the design or pattern required. *Patent completed.*

80. D. Collinge. *Improvements in machinery or apparatus for cleaning and preparing cotton or other fibrous materials to be spun.* Dated January 9, 1863.

This invention consists in adapting the ordinary fan to the purpose of cleaning and steaming the fibrous material preparatory to spinning. The inventor feeds the cotton or other material to the fan by means of an endless band made of laths or other suitable material, and he fixes a grid inside the fan to allow the dirt or refuse to fall through it. At the exit side of the fan he fixes a wire tube, through which the fibrous material passes into a steam chamber, being further cleaned as it passes through the said wire tube. He causes a supply of steam to the said chamber by the means of pipes, so that, as the fibrous material enters the chamber from the wire tube, the steam from any convenient number of pipes penetrates and saturates it. *Patent abandoned.*

81. W. H. Moreland and J. Chappell. *Improvements in winding, warping, beaming, or dressing machines.* Dated January 9, 1863.

The object of this invention is to secure a uniform tension of the yarn on the beam to which it is being transferred from spools or bobbins. The invention consists in the application to the ordinary winding, warping, beaming, or dressing machines that wind from the spools or bobbins, of a drag roller or rollers for taking up the slack yarn caused by the over-running of the spools or bobbins from which the yarn is being wound. *Patent completed.*

82. G. B. Price. *Improvements in sights for firearms.* Dated January 9, 1863.

This invention relates to certain improvements in the sights for firearms, whereby the person using the weapon can at once see whether the sights are perfectly vertical on bringing the weapon to the position for firing. According to this invention, it is proposed to attach a small spirit or liquid level to the side of the flap of the elevation sight, such level being placed transversely to the bore of the barrel. The said slide is like the one ordinarily used, but with the addition of two lugs or projections, one on either side, for the reception of a small glass level, which level may readily be replaced in case of accident, as the one lug or projection is left open for that purpose, and then stopped by clay, wax, or any other convenient substance. It is proposed to attach a guard, so that the level may not be broken when not in use, which guard may be made in a variety of ways, either by having a stationary piece of metal fixed to the flap below the slide, or by fitting a piece of metal to slide over the level, or by having a piece of metal to fall down over it, or in any other convenient way. *Patent abandoned.*

83. W. Tasker, jun. *Improvements in the construction of harrows.* Dated January 9, 1863.

This invention relates to a peculiar construction and arrangement of the frame of harrows. According to this arrangement, it is proposed to employ separate truss bars between the several longitudinal beams of the harrow frame, and to connect such truss bars to the beams in such positions as will afford the greatest strength, by preference at right angles to the beams, which when made zig-zag gives a different trussing; any other angle, however, may be adopted. The truss bars are formed with a shoulder or collar near each end, and are either bolted to the beams or keyed thereto, the ends of the truss bars passing through the beams. Or these bars may be formed with a foot at one or both ends, and secured in the one case by passing the end of one bar through the beam and foot of the next bar, and screwing by means of a nut, key, or riveting; or in the other case by a separate bolt, pin, or rivet passing through both the feet of the contiguous ends of the bars, and through the beam. *Patent completed.*

84. M. Henry. *Improvements in furnaces.* (A communication.) Dated June 9, 1863.

This invention relates to certain regenerator and current reversing furnaces or heating apparatus, patented by Mr. Siemens, in which four regenerators are employed, two of which receive the waste heat of the products of combustion on their way to the chimney, while the third imparts heat to the combustible gases proceeding from their generator, and the fourth imparts heat to the air, the said combustible gases and air combining and evolving a high temperature, valves being employed to reverse the direction of the aeriform or gaseous currents, so that the two regenerators which before received heat from the products of combustion will receive and heat the entering air and combustible gases, while the two others will, in their turn, receive heat from the departing products of combustion. The inventor wishes it to be understood that this immediately foregoing method or arrangement for heating is not of his invention, and he lays no claim to the same considered separately and apart from the application and combination thereof as hereafter set forth and expressly claimed. Now, the present invention has for its object a mode of adapting the said method of heating to the purpose of performing various chemical, metallurgical, and other manufacturing processes, in which are two consecutive operations or stages requiring different temperatures. And the invention consists in applying or combining the before described regenerator and current reversing arrangement with two combined furnaces, hearths, ovens, kilns, or heated or working chambers, in such a manner that by the reversing of the currents each such furnace, hearth, oven, kiln, or chamber shall be alternately brought to the proper temperature for each such operation or stage, and so that the two stages or operations may be performed in each furnace, hearth, oven, or working chamber alternately, and both stages or operations may thus be carried on at the same time in the same apparatus, though in each of its said furnaces, hearths, or chambers in turn. *Patent completed.*

85. W. Grove. *An improved apparatus applicable to the sawing and cutting of wood or other light substances.* Dated January 10, 1863.

This invention consists of a rectangular framework or standard framing of suitable material, upon which an endless band saw, in connection with a fly-wheel, crank shaft, and strap wheels are employed, the said crank shaft or fly-wheel being driven or set in motion through the medium of winch handles or treadles, and the operation of cutting performed by passing the plank or otherwise transversely with the saw, which is made to revolve by means of the said strap wheels secured top and bottom, and tightened thereon by set screws or otherwise. *Patent abandoned.*

86. W. Grove. *Improvements in apparatus for sawing wood and other substances.* Dated January 10, 1863.

This invention has reference to the mode of mounting and employing circular saws for cutting or shaping wood, or otherwise rendering the same available for the general purpose to which such apparatus is or may be employed, and consists in arranging the said saws so as to receive motion direct from the axis upon which the fly-wheel is mounted through the intervention of tooth and pinion, or strap wheel gear, in such manner as to admit of being worked by the hands or feet, and regulated or adjusted to the required speed. *Patent abandoned.*

87. R. Luthy. *Improvements in hydrostatic presses.* Dated January 10, 1863.

This invention relates—1, To presses in which the piston or ram has to pass through the whole length of the stroke or lift, and consists in raising or moving the ram through the first or principal part of the stroke by means of a screw or screws, or by rack and pinion motion, or by other suitable mechanism; but the patentee prefers to use one or more smaller hydraulic rams for effecting this object. The said mechanism or apparatus may be connected with the press piston or larger ram through the press plate commonly called follower, or it may be made to act upon a rod passing through the bottom of the cylinder, and bearing direct upon the ram. 2, The improvements relate to those hydraulic presses in which the stroke of the larger ram may be shorter than the lift required for the whole operation. For this purpose the patentee proposes to effect the first part of the stroke by means of a cylinder and ram of the requisite length, but small diameter, and therefore of comparatively small weight. 3, The improvements relate to apparatus for supporting the platform or follower, or the cylinder and rams upon which the material to be compressed rests; for instance, when the small ram has completed its stroke. These apparatus consist, again, in small hydraulic cylinders, into which the fluid is allowed to enter, whilst their rams attached to the follower rise through the first part of the stroke. When the rams are not in motion, the suction valves will close and prevent the escape of the fluid, which will now support the pressure or weight resting upon them. *Patent completed.*

88. M. Vogl. *An improved fastening for bags and other articles.* Dated January 10, 1863.

This invention consists in constructing a fastening in the following manner:—One of the engaging members or portions of this fastening consists of a catch, hook, pin, notched arm, or piece fixed or formed on an arched, bent, or two-limbed piece, or, as the patentee calls it, a bridge piece, the two limbs of which work in or through a box case or frame in which is a spring or springs. The catch engages and disengages a recess, staple, socket piece, or part forming the other engaging member or portion of the fastening. These two members or portions of the fastening when engaged effect the fastening action, and they are kept engaged by the pressure of the springs on the limbs of the bridge piece, and they are disengaged by pressing the bridge piece downward or against the spring or springs. In applying the fastening to bags and like articles the patentee preferably arranges the engaging parts on the outside or upper side of the bag frame, and not on the inside or under side thereof, and he places the catch bridge piece and springs on one jaw of the frame, and the other engaging member on the other jaw. He prefers to shape the case which holds the springs like the box or case of a padlock. *Patent completed.*

89. L. H. E. Lepreux. *Improved hygrometric plates proof against salt-petrous humidity.* (A communication.) Dated January 10, 1863.

The object of these plates or slabs is to preserve apartments from the effects of damp. Placed on the inside of a wall even contiguous to a reservoir full of water, or the stones of which soaked with water are already salt-petred, they will preserve the hangings or tapestries from damage or dilapidation. They may at pleasure be prepared and arranged to receive a coating of plaster or mortar, paintings or paper hangings, and are composed of resin, plaster, sand, and gravel or flint, in about the following proportions—say, for a slab of one superficial yard, 8 lb. of resin, 8 lb. of plaster, 8 lb. of sand, and 48 lb. of gravel or flint. In laying or fixing these slabs a martingal or tiepiece is placed at each joint, which is closed with some of the same composition as that of the slabs, which thus united form one whole secured to the wall by cramps or claws galvanized to prevent oxidation. Plinths and foundations for walls may be made of the same compositon. *Patent abandoned.*

90. F. Fenton. *Improvements in the manufacture of pulp for paper-making and similar purposes.* Dated January 10, 1863.

This invention consists in preparing exhausted tan, tanners' waste, the bark of oak, elder, elm, lime (or linden), willow, and poplar trees into paper pulp or half-stuff for the manufacture of paper, cardboard, and papier mache. *Patent completed.*

91. E. Powers and J. G. Dale. *Improvements in the manufacture of caustic soda and potash, and carbonates, chromates, and stannates of the same alkalies.* Dated January 10, 1863.

In the manufacture of caustic soda and potash the inventors produce those substances direct from the chlorides by treating them with steam as it is evolved or superheated. The method they adopt is to place the chloride in a suitable vessel, so that the material may be heated and fused, and they then cause the steam to pass through the mass by means of a pipe which dips downward, or by other suitable arrangement, which will after the same manner bring the steam into immediate connection with the chloride. To assist the conversion into caustic alkali they propose, if found necessary, to add metallic iron, or oxide of iron, alumina, manganese, or other suitable metals or metallic oxides. When they desire by this process to produce carbonates of the alkalies, they combine a jet of carbonic acid with the steam; or if chromates or stannates be desired, they substitute for the metals above alluded to chrome iron ore, or oxide of chromium, or tin stone, or metallic tin, as the case may be. *Patent abandoned.*

92. D. Dawson. *Improvements in manufacturing magenta colour or dye.* Dated January 12, 1863.

In carrying out this invention, the patentee mixes a solution of arsenic acid with aniline in equivalent proportions, so that a neutral salt of arseniate of aniline is formed. The solution of arsenic acid is such that it contains from 23 to 30 per cent. of water, including water of hydration. The acid containing 23 per cent. of water is liable to deposit crystals, but they may be used along with the mother liquor, as arseniate of aniline will in that case be formed as well as if the arsenic had been all in solution. When the mixture is made and cooled, it is a solid substance, usually white, having a somewhat crystalline aspect. This substance contains all the water which held the arsenic acid in solution, perhaps as water of crystallization. The

patentee then puts this arseniate of aniline (plus water) into a strong iron cylinder capable of resisting a pressure of about 200 lb. on the square inch. The cylinder is provided with an air-tight fitting lid, in which a pressure guage is inserted. He now bolts the lid on. The cylinder being prepared as above, he places it in a bath capable of being raised up to the temperature of from 350 deg. to 360 deg. Fahr. The bath he now raises up to a temperature of about 345 deg. or 350 deg., by applying heat by a sand bath, or by a naked fire; care must be taken to keep the temperature about 345 deg. or 350 deg. Fahr. for the space of about 12 hours. He does not confine himself exactly to 12 hours, as the time necessary for producing the required result will vary according to the size of the apparatus. The pressure will get up as high as from 70 lb. to 100 lb. on the square inch. He has now produced the colour, and it only needs taking out of the cylinder and purifying by some well-known method. *Patent completed.*

93. E. D. Chattaway. *Improvements in railway signals.* Dated January 12, 1863.

This invention consists—1, In adapting the cord and bell or cord and whistle arrangement or signal at present in use for enabling the guard of a train to communicate with the engine driver so as at the will of the guard to convert such arrangement into an electro-galvanic or electro-magnetic signal. This the inventor proposes to effect by enclosing copper or other suitable wire or wires, properly insulated in the cord of the arrangement before referred to, and connecting the same with a galvanic battery or magnetic apparatus in the guard's van. 2, In constructing railway semaphore and other similar signals of sheet iron, either coated or not coated with vitreous enamel, or other similar material. *Patent abandoned.*

94. E. Stevens. *Improvements in ovens, hot plates, and cooking apparatus.* Dated January 12, 1863.

This invention is not described apart from the drawings. *Patent completed.*

95. W. Clark. *Improvements in winding or copping frames.* (A communication.) Dated January 12, 1863.

This invention relates—1, To the employment of a fixed apparatus for lowering the faller to the point of the spindles in winding or copping machines, and at the same time stretching or keeping in a fixed position the chain, cord, or other intermediate apparatus between the scroll or pointer barrel and the faller before the pointing and during the latter portion of the motion of the carriage only. 2, In the application of a double pulley or variable connection between the faller and the ratchet pointer, situate on the shaft of the drum spindles, in order that the course of the faller shall be always in the required relation with the number of turns of the spindles during the pointing. 3, In the employment as an intermediate agent between the apparatus conducting the faller (rule or copping plate) and the faller of a combination of parts knee-jointed and constructed in such manner that the projections on the spindle and the spaces traversed by the faller may be proportionate to the variations of the conducting apparatus. *Patent abandoned.*

96. W. Clark. *Improvements in carding engines.* (A communication.) Dated January 12, 1863.

This invention consists in substituting for the reciprocating roller of the large cylinder in carding engines a flyer with continuous motion, which, instead of stripping the large cylinder in front of the doffer, effects the said operation in front of the feed rollers, at a point before the cylinder arrives at the feed roller, whether it is furnished with a licker-in or not, and after the doffer has acted. *Patent abandoned.*

97. W. Clark. *Improvements in the preparation of green colouring matter.* (A communication.) Dated January 12, 1863.

The inventor claims the preparation of a green colouring matter derived from aniline, which is soluble and suitable for dyeing and printing purposes, by means of a combination of reducing agents, such as hydrates and soluble hyposulphites acting on acidulated solutions of salt and rosaniline, or on the blue or violet compounds derivable from the same. *Patent completed.*

98. A. I. Mahon. *Improvements in screw and paddle propellers, and a submarine propeller, also applicable to the raising and forcing of water or other fluids.* Dated January 12, 1863.

This invention relates to various forms of screws and screw blades, and their combination and arrangement, so that the vacuum caused by the ordinary working of their different currents may be taken advantage of, and so that the centres of screws may be made to work more effectively, and for the employment of the principle that the natural tendency of water is to overcome vacuum, whether produced artificially or not, in the form of a propeller that may combine the advantages of the paddle and screw, and which may be called a paddle. *Patent abandoned.*

99. W. E. Newton. *Improvements in the application of power designed for stationary and traction engines, propellers, and other machinery.* (A communication.) Dated January 12, 1863.

This invention relates to the employment of a system of dogs or driving catches for operating upon the interior of the rim of a wheel or pulley for the purpose of producing its rotary motion. These dogs or driving catches are arranged in two sets, and are applied in connection with a lever or levers arranged to oscillate upon the shaft of the wheel or pulley, so that in the movement of each of the levers in one direction the dogs will work free of the rim, and in its movement in the opposite direction, they will bite the rim, and thereby transmit a rotary motion to the wheel or pulley, and to its shaft. This part of the invention consists in certain devices employed in connection with this double system of dogs to provide for the reversal of the rotary motion at pleasure. The invention further relates to a certain means employed for varying the application of the driving power, whereby, when required, speed may be decreased, and a proportionate increase of power obtained, and the utmost capacity as regards speed obtained when desired, and a steam engine rendered capable of being used as either a traction or stationary engine. *Patent completed.*

100. T. G. Lewis. *Improvements in apparatus applied to perambulators, invalid chairs, and other carriages.* Dated January 13, 1863.

This invention relates to the application of moveable arms to perambulators, invalid and other carriages, for the purpose of holding or supporting children, invalids, and other persons in such vehicles, and also to offer support or rest for the arms. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated May 27, 1863.

1328. A. P. Hernandez and P. B. Crespy, Bordeaux, France. Improvements in the manufacture of soap.

Dated June 22, 1863.

1562. E. Wilks, portmanteau-maker, Cheltenham. Improvements in making portmanteaus and trunks of various shapes and sizes, light, strong, air-tight, and water-tight, capable of bearing immersion in water without injuring the contents.

1565. W. Snell, 16, Clement's-inn, Strand. Improvements in arrow-shaped projectiles, and in guns for discharging the same.

Dated June 24, 1863.

1591. P. R. Hodge, 25, Cannon-street, City, civil engineer. Improved floating hydrostatic machinery adapted to presses, dry docks, slips, or the moving or lifting of heavy masses, parts of which are applicable to the expressing of oil or other fluids.

1593. S. Smith, 5, Fell-street, City. Improvements in the manufacture of liquorice, and in the means or apparatus employed therein.

Dated June 29, 1863.

1619. G. Davies, 1, Serle-street, civil engineer. An improved cork-cutting machine.

Dated July 2, 1863.

1651. J. King, Chadshunt Farm, near Kineton, Warwick. Improvements in fencing land and in hanging gates.

Dated July 4, 1863.

1664. R. Flude and J. Farndon, Aylestone-street, Leicester. Improvements in looms for weaving narrow fabrics.

Dated July 6, 1863.

1675. T. W. Couldery, Old Kent-road. Improved means of attaching boxes or receptacles to hold soap, black lead, or similar household articles to the sides of wash-tubs, pails, or house boxes.

1677. S. J. Cooke, 2, St. Michael's-house, Cornhill. Improvements in apparatus for supplying carbonic acid gas to casks or other vessels containing beer or other fermented liquid. (A communication.)

1679. B. Bonfield, Forest-hill, commercial traveller. Improvements in stoppers for bottles.

Dated July 7, 1863.

1682. L. J. Guichard and G. F. J. Lefebvre, 10, Rue de la Fidélité, Paris. Improvements in lamps, and in the wicks used in such lamps.

1683. W. S. Bruce, Great St. Helen's, Bishopsgate-street. Improvements in lucifer matches, fusees, and other similar lights, and in the boxes or holders for containing the same. (A communication.)

1685. G. Bartholomew, Linlithgow, edge tool maker. Improvements in shoes for the feet of horses and other animals, and in the means of connecting them.

1689. S. Robinson, 129, Great Brunswick-street, Dublin. Improvements in spring hinges for swing doors.

Dated July 8, 1863.

1691. E. Myers, Millbank-row, civil engineer, and H. Forbes, 6, Aberdeen-place, Maida-hill. An improved method of propelling and steering ships.

1693. W. Basford, Pewsey, Wilts, engineer. Improvements in apparatus for generating and purifying gas made from coal or other bituminous substances.

1697. P. A. L. de Fontainemoreau, 10, Rue de la Fidélité, Paris. A new mode of roofing houses, buildings, and other structures. (A communication.)

1699. A. G. Southby, Bradford, Wilts, engineer. Improvements in divers lamps.

1703. H. D. P. Cunningham, Bury, Hants, esquire. Improvements in working guns, and in matters relating thereto.

Dated July 9, 1863.

1705. S. Davis, 33, Strand, saddler and harness manufacturer. An improved anatomical bit for horses or other animals. (A communication.)

1706. J. Smith, Berkeley-house, Seaforth, Liverpool, and S. A. Chease, Egremont, Chester. A new description of hydraulic engine for raising water and other fluids above their common level, the fluids so raised to be used as a motive power.

1707. W. Williams, Gutter-lane, Cheapside. Improvements in shirt collars and boys' and ladies' collars.

1709. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in ships and in propelling the same. (A communication.)

1711. J. F. Delany and J. C. R. Okes, Victoria Foundry, Greenwich. Improvements in the pistons of steam engines.

1715. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in barometers or gauges for measuring the pressure of fluids. (A communication.)

1717. G. Gowland, Liverpool, chronometer-maker. Improvements in the construction and arrangement of nautical and surveying instruments for measuring angles and altitudes.

Dated July 10, 1863.

1719. P. A. Godefroy, 7, Shepherd's-lane, Homerton, operative chemist. Improvements in the mode of purifying oils.

1721. M. A. F. Mennons, Abingdon Chambers, Westminster. Improvements in the mode of preserving and protecting the silvering of mirrors. (A communication.)

1723. C. de Bergue, Strangeways Works, Manchester, engineer. Improvements in piles for foundations, and in piers for bridges and other buildings or structures.

1727. W. E. Jones, 22, Wellington-road, Clapham, civil engineer. Improvements in the permanent way of railways.

1729. J. P. Bourquin, Newman-street, Oxford-street, manufacturer of photographic goods. An improved construction of rolling press.

1731. R. H. and W. Hawthorn, Newcastle-upon-Tyne, engineers. Improvements in the working of railways.

Dated July 11, 1863.

1733. E. D. Chattaway, New Broad-street, London, engineer. Improvements in railway signals.

1737. J. Barnes, Nottingham, mechanic. A new machine for clipping off connecting threads in the manufacture of lace.

Dated July 13, 1863.

1741. R. D. Dwyer, Warrington, engineer. Improvements in the construction of vents for casks and other vessels.

1745. J. Barton, Alfreton, Derby, colliery manager and coal merchant. An improved guard or fence for coal, iron, stone, or other pits, warehouse or other lifts, sack-holes, or other places requiring a guard or fence.

1747. G. H. Barber, Southampton, accountant. An improved calendar or date-denoting apparatus.

1748. J. Laing, 80, George-street, Manchester, drysalter. Improvements in dyeing or printing. (A communication.)

1751. P. C. A. Iodocius, Dunkerque, France, merchant. Improvements in fishing, and in the apparatus or means to be employed therein. (A communication.)

Dated July 14, 1863.

1753. L. M. Bouruique, mechanician, and J. B. Vidard, engineer, Paris. Certain improvements in railway carriages.

1754. L. M. Bouruique, mechanician, and J. B. Vidard, engineer, Paris. An improved waggon or truck to be used on railways.

1755. J. R. Cooper, Birmingham, gun manufacturer. Improvements in sights for rifles and other firearms.

1757. J. T. Cooke, Leicester, batten maker. Improvements in and connected with battens for driving shuttles from side to side of their work in weaving.

1759. G. Saxon, Openshaw, engineer. Improvements in metallic pistons.

1761. R. Hornsby and J. E. Phillips, Spittlegate Iron Works, Grantham. Improvements in reaping and mowing machines.

1763. E. Sonstadt, Loughborough. Improvements in the manufacture of sodium.

1767. E. Funnell, Brighton, watch and clock maker. A self-acting electro-magnetic clock-work signal for railway purposes.

1771. W. Clark, 53, Chancery-lane, engineer. An improved process for making paper transparent and transferring designs. (A communication.)

1773. M. Henry, 84, Fleet-street. Improvements in figuring, ornamenting, and colouring fulled and felted fabrics and articles. (A communication.)

1775. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in apparatus for telegraphing by electricity. (A communication.)

1777. D. Tamet, 103, Vieille Route à Neuilly sur Seine, France. Improvements in breakwaters and in the construction of rail and other ways thereon.

Dated July 15, 1863.

1779. A. Watson, Glasgow, stove grate manufacturer. Improvements in cooking ranges.

1781. J. N. Taylor, Brixton, Retired Admiral, and W. Austin, Milford, South Wales, civil engineer. Improvements in the construction of ships and other floating bodies.

1783. L. Priestley, Bradford, and J. Todd, Morley. Improvements in the manufacture of elastic boots and shoes and in apparatus used therefor.

1789. B. Lambert, 35, Lothian-road, Camberwell New-road. Improvements in the preparation of waste paper in order to its being again used in the manufacture of paper.

1791. N. Thompson, 15, Abbey-gardens, St. John's-wood, Middlesex. Improvements in boat-building, and in machinery for shaping wood therefor.

Dated July 17, 1863.

1793. A. J. Sedley, 210, Regent-street, London, upholsterer. Improvements in the canopies of bedsteads of metal or wood, or both combined, and other articles of furniture used to sit or recline upon.

1796. F. Lepoutre, Tourcoing, France, manufacturer. A new mechanical sector applicable to all self-acting machinery used for spinning textile fabrics.

1797. T. Johnson, Hadleigh, Suffolk, engineer. Improvements in machinery for washing and cleansing casks.

1799. R. A. Brooman, 166, Fleet-street, patent agent. An improved varnish for preserving metal and wood. (A communication.)

1801. R. Coenen, 19, Old Broad-street, City, silk merchant. Improvements in machinery for winding, measuring, and sizing silk. (A communication.)

1802. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in machine knitting needles, and in machinery or apparatus for making the same. (A communication.)

Dated July 18, 1863.

1803. A. Clark, Gate-street, Lincoln's-inn-fields, engineer. Improvements in revolving shutters and blinds, and in apparatus for the manufacture of the same.

1804. W. C. Page, Gabrick-street, Millwall, engine

driver. An improved mode of preventing and removing the incrustations in marine and land steam boilers.

1806. E. Holborow, Buckingham-street, Fitzroy-square, and I. Parker, Houghton-street, Clare-market. Improvements in the construction of sights for firearms.

1807. F. J. Mavor, Park-street, Grosvenor-square, veterinary surgeon. Improvements in horse shoes.

Dated July 20, 1863.

1809. F. A. Calvert, Manchester, engineer. Improvements in machinery for opening, cleaning, and preparing fibrous substances.

1811. T. Knowles, Hulme, gentleman. Improvements in machinery for opening, carding, and cleaning cotton and other fibrous materials when in a manufactured or partly manufactured state.

1813. A. Smith, Stratford, brush manufacturer. Improvements in machinery for dragging bristles, applicable also to drawing or sorting fibres and hair into different lengths.

1815. A. A. Pelaz, Lyons, France, gentleman. Certain improvements in printing stuffs and other fibrous fabrics.

1817. J. Lyman, Thavies-inn, civil engineer. Improvements in micrometer draughting scales.

1819. J. Goold, Corsham, Wilts, tanner. Improvements in the manufacture of ink.

Dated July 21, 1863.

1820. F. L. H. Danchell, Red Lion-square, civil engineer. Certain improvements in apparatus for purifying water.

1823. W. L. Aberdeen, Belfast, mill manager. Improved machinery for breaking or softening and preparing flax, hemp, jute, tow, and other fibrous substances.

1825. E. T. Bainbridge, St. Paul's-churchyard. Improvements in ventilators.

1827. G. Haseltine, Southampton-buildings, Chancery-lane, civil engineer. An improved implement for harrowing and smoothing land. (A communication.)

1829. E. Alcan, King-street, merchant. Improvements in apparatus for condensing steam. (A communication.)

1831. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in the manufacture of mats, floor cloths, or coverings for floors, straps, bands, ropes, and other analogous articles which are usually made of textile or fibrous materials. (A communication.)

Dated July 22, 1863.

1835. J. White, Trinity-street, Trinity-square, manufacturer. Improvements in pyramid and other cans or feeders for oils and other liquids.

1836. C. Beslay, Rue Menilmontant, Paris, gentleman. Improvements in making all woven and thready fabrics waterproof. (A communication.)

1839. J. Simmons, Rainham, Sittingbourne, agricultural implement maker. Improvements in ploughs.

Dated July 24, 1863.

1850. J. Kirkland, Liverpool, engineer, improvements in apparatus for working hydraulic presses.

1852. A. English, Hatfield, Herts, inspector of police. Improvements in apparatus for securing and protecting horses and other cattle during their transit by rail and other ways, and on board ship.

1854. B. Birnbaum, 21, New Broad-street. Improvements in gaiters and leggings.

Dated July 25, 1863.

1856. G. H., J. M., and J. James, 10, Dyer's-buildings, Holborn. Improvements in the manufacture of covers for purses, wallets, and pocket-books.

1860. C. Crockford, Greenfield Spelter Works, Holywell, Flintshire, smelter. Improvements in the treatment and utilization of certain of the waste products from the manufacture of alkali and bleaching powder, and also from certain smelting operations.

Dated July 27, 1863.

1862. W. Tranter, Birmingham, gunmaker. Improvements in breech-loading and other revolving firearms.

1864. T. Thorne, Southsea, Hants, carpenter. Improved apparatus for disengaging ships' boats.

1866. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in sleepers or supports for the rails of railways. (A communication.)

1868. J. Whittaker, Mons Mill with Walton-le-Dale, Lancaster, millwright. Improvements in engines for obtaining motive power by steam, air, or any other vapour.

Dated July 28, 1863.

1874. J. Jewell, Devoran, near Truro, Cornwall. Improvements in setting boilers.

Dated July 29, 1863.

1876. J. Sainty, Burnham Market, Norfolk, agricultural engineer. Improvements in the construction of feeding troughs for sheep and other cattle.

1878. N. Thompson, Abbey-gardens, St. John's Wood. Improvements in apparatus for stopping the bung-holes of casks and similar vessels, also in tools or implements for fixing and removing such stopping apparatus.

1880. H. A. Bonneville, 24, Rue du Mont Thabor, Paris. An improved self-acting flushing apparatus. (A communication.)

1882. E. Sturge, Walworth, engineer. Improvements in coating or protecting metallic surfaces.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated July 31, 1863.

1900. R. Stewart, Elmira, New York. Improvements in operating the cut-off valves of steam engines.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, August 11, 1863.

813. W. Symonds. Barometers.
814. G. Thomas. Window shutters and blinds.
820. J. Carver. Carriages employed in machines for making lace.
824. E. T. Hughes. Composition for rendering cloth, paper, and similar articles transparent and waterproof. (A communication.)
826. A. B. D. Maurand. Apparatus for bringing the former weights and measures into those of the present decimal system most easily and precisely and *vice versa*.
835. J. Hindle, W. F. Calvert, and E. Thornton. Looms.
836. I. Rowland. Mileage apparatus.
837. J. Bray. Omnibuses and railway carriages.
841. W. Mitchell. Coating iron. (A communication.)
850. J. J. Potel. Furnaces and fireplaces.
854. A. B. Seithen. Casings or covers for bottles or jars.
856. J. Blain. Threads and yarns.
857. P. Hanrez. Drying coal, grain, and other substances.
870. J. Burwin. Pickers.
877. J. H. Johnson. Polishing precious stones. (A communication.)
884. J. Mosheimer. Crushing, grinding, and dressing metallic ores.
890. J. L. Norton. Washing and drying wool.
891. A. Kinder. Coating or covering lead.
910. R. Smith. Medicated oil.
940. R. A. Brooman. Hardening and colouring gypseous limestone and sand. (A communication.)
941. R. A. Brooman. Lamps. (A communication.)
943. J. Leach. Machine for washing, squeezing, mangling, and churning.
948. A. Marriott. Boilers for heating buildings.
960. A. Samuelson. Apparatus for the manufacture of oil.
1011. W. Clark. Tiles. (A communication.)
1012. T. Richardson and J. C. Stevenson. Sulphate of soda.
1063. A. Kinder. Manufacture of sheet metal.
1106. J. B. Dubreuil. Carts, waggons, and other vehicles.
1161. J. Stickland. Laying veneers on to surfaces.
1197. R. A. Brooman. Preparing, dressing, and winding cotton, woollen, flax, silk, and other warps. (A communication.)
1262. J. Coignard. Sewing machines.
1389. F. S. Barff. Preserving and hardening surfaces of brick, cement, stone, and stucco.
1485. J. S. Benson and D. Jones. Removeable head for casks.
1748. J. Laing. Dyeing and printing. (A communication.)
1826. J. E. Vanner. Umbrellas and parasols.
1844. G. Davies. Firearms. (A communication.)
1862. W. Tranter. Breech-loading and other firearms.
1900. R. Stewart. Valves of steam engines.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed August 10, 1863.

388. J. Jones.
392. W. Robertson.
393. G. Wrigley & S. Morris
394. O. H. Hodge.
401. J. S. Gisborne and W. Simpson.
410. J. and H. Higgins.
415. J. W. Crossley.
416. C. D. Abel.
420. R. A. Brooman.
423. S. W. Clough.
424. W. Nalder.
426. T. W. Salmon.
513. G. Bower and W. Hollinshead.
528. T. V. Lee.
561. J. H. Johnson.
708. W. E. Newton.
808. B. W. Goode.
903. G. Low.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

1889. R. Bodmer.
1908. R. A. Brooman.
1923. M. Dobbs.
1926. G. H. Newton and A. Wild.
1945. R. Smith.
1965. N. Wehnert.
2015. E. Hall.
2046. G. Kershaw.
2052. E. T. Truman.
2055. R. Jobson and R. J. Ransome.
2088. R. Perrott, jun., and J. Molony.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

1840. H. W. Wood.
1854. J. Y. Borland.
1876. T. Whittaker.
1885. J. Cartland.
2006. B. A. Grautoff and C. H. W. Albrecht.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, AUGUST 21, 1863.

THE ENGINES OF OUR NAVY.

It is very unlikely that the contest between guns and armour-plates will soon be brought to a satisfactory termination. Ordnance of every possible construction, is employed with varying success to pierce or shatter targets, in which iron is combined, and built up with all sorts of materials from papier maché to steel. Armstrong, Whitworth, and Co., and their supporters, still do their best to prove the whole system of iron-plating fallacious. Money is expended with no niggard hand, nor is it likely that the country will refuse supplies, until the experiments have attained some definite result, some fixed point which will serve to guide us in our future proceedings. Still, it is improbable that such a result will be reached for many months, if not years, to come. Just now, we cannot consider the best form for a fighting ship as being settled conclusively, or even approximately; nor yet her size; while the description of guns with which she is to fight, and the kind of armour to protect them, are equally matters of opinion, hitherto decided on, far more frequently from conjectural reasons, than because of those which follow as natural deductions from experience. That matters will improve, and that ere long we will thoroughly understand which is the best gun, and the best ship, and the best armour, and the best of many other things connected with our Navy, we do not doubt; but the most careful and disinterested investigation fails as yet to discover any result from all this expenditure of money, and talent, and discussion, which does not admit of dispute save one, which is, that the ship capable of steaming fastest and manœuvring most readily, is, other things being pretty equal, the best for all the purposes of attack and defence. This sole qualification of speed, indeed, may compensate very well for defective ordnance, inferior armour, a weak crew, or a hundred other things which might, without it, render a war ship comparatively inefficient as such. However much engineers and sailors may disagree on other points, on this at least they are agreeably unanimous. It is quite true, that an iron-plated ship may be employed with advantage in many situations where speed is in no wise necessary to her, or at least can be very well dispensed with, whilst she is fulfilling her legitimate purpose, as in attacking a fort; still, even the so-called floating batteries, built expressly for such an object, would be none the worse could they steam 14 or 15 knots an hour in a sea-way when occasion required, as well as lie quietly in one place to shoot, and be shot at; and what holds true of such vessels as these, applies with equal force to every ship in the Navy. The excessive weight of their armour, their guns, their propelling machinery, and the fuel required for a few days' cruise has effectually kept the speed of our iron-plated frigates, great as it is, below the attainable limit, and even while the gun and armour question is carried on with a spirit and energy which will, we trust, lead to highly satisfactory results, it might be as well perhaps that the Government, instead of concentrating all its powers on a problem which is no longer new, should devote yet a little more of their attention to the best means of attaining the high speed, which will enhance every advantage to be derived from the best possible guns, and the most perfect system of iron-plating.

Reliable calculations which would give us the average speeds of the principal steam navies of the world would be very valuable. Similar information respecting the mercantile steam marine of different nations would not be less so. The necessary data, however, are not in existence, or not available. We have, it is true, returns more or less accurate of our own ships and their performances, and this is about the limit of our knowledge on such subjects. It is quite enough to prove that the speed of our Navy, at all events, is below that maintained by the fleets of our steam-ship companies, who could easily select dozens of ships which would beat the fastest frigates, screw or paddle, we have afloat. The mail-boats from Kingstown to Holyhead can manage 20·5 statute miles an hour now and then. The "Victoria and Albert's" speed is over 19 miles an hour. The "Pera" has averaged 17·5 in a run of 1,000 miles from Malta to Alexandria. The river boats on the Clyde, small as they are, can perform over 20 miles per hour, trip for trip. We might fill this column with a mere list of the names of steam-ships not in our Navy, which exceed in speed, by a couple of knots an hour, the fastest frigates in it. We do not wish to make this comparison in an invidious sense. We cite such facts to remind our readers of the possibility of attaining a far higher speed than anything our fighting ships have yet displayed.

When dealing with this question we must, however, bear in mind that whatever theorists may say, there is for the present a certain practical limit to the speed of a ship; a limit which can only be exceeded by having recourse to certain exceptional arrangements, which entail the sacrifice of many other things which ships, as a rule, cannot dispense with. A speed of 20 miles an hour is about the maximum which can be realized satisfactorily. With such a velocity we have good reason to rest content. Without going to this limit, we find a large class of merchant steamers accomplishing 18 miles per hour with ease and certainty, and it becomes, for various reasons, a matter for serious consideration, that some at least of our "crack" iron-plated frigates should be constructed and engined to attain a like speed when occasion required. In the third report of the British Association on Steam-ship Performance, we find that the speed of the "Duncan" is stated as being 13·33; that of the "Victoria," 13·14; of the "Howe," 13·56; "Mersey," 13·29; and "Orlando," 13·16 knots per hour. To this we may add the "Warrior," 14·3; and the "Royal Oak, 12·5." This list includes the fastest ships of war we have afloat, the great mass of our Navy being far—we are afraid to say how far—inferior in speed. Things are somewhat altered since the palmy days of sailing ships, when our frigates ranked amongst their number the fastest craft which went to sea. Then these ships had, as a rule, to wait for the convoy they protected. We much question that such would be the case in the event of a modern war. Many of our clipper sailing ships, with and without auxiliary engines, can sail faster than the vessels which would be available as escorts; and the man-of-war deputed to watch over and protect a fleet of merchant steamers would need to be carefully selected, in order to fulfil her duties as she ought. The increase in speed in our Navy has not kept pace with that of our trading ships; too much, possibly, being thought of armament, and too little of that speed which is essential to its proper use; and this, while recent events demonstrate that escort frigates cannot yet be dispensed with in warfare.

It is fortunate that the relative merits of paddles and screws have been settled long since definitively. Had it not been so, we would have animated discussions and costly experiments on this subject, as well as on guns, targets, &c., to increase the complication of affairs. For once, however, that which is scientifically correct is practically so as well, and the screw reigns supreme over all other modes of propulsion for ships whose mission is war. Were it not so, the proportion of sailing ships in our Navy would have remained unavoidably large, for reasons well exemplified by our old paddle-wheel frigates; and we should have heard little of armour, but for submerged propellers.

The screw is in its infancy, as far as the Navy is concerned, inasmuch as we have not as yet availed ourselves of many important advantages which its use holds out. Doubled, as in the "Diana" or "Flora," it affords, apparently, the best of all means for manœuvring, without perhaps entailing any very great practical difficulties. Too little is as yet known about the application of this principle to large vessels to enable us to speak decidedly. It is just one of those inventions which promise well, and therefore it deserves careful consideration. The screw, however, in its present form indirectly supplies us with the means of increasing the speed of our ships without an increase in the consumption of fuel. We state this as a proposition which will scarcely be disputed by those who have given the subject due thought. The screw alone permits the legitimate use of high speed in the crank shaft, high pressure, and the extension of the principle of expansion to its proper limit; three elements sufficient in themselves to secure a very superior degree of economy to any they yet attempted generally in the Navy. The small number of strokes per minute in large paddle engines causes such a tedious isolation of the expanding steam in their cylinders, that no appliances available under the circumstances can prevent condensation to a degree which sets economy at defiance. For a like reason, it is impossible to realize anything like a high speed of piston, and in consequence power must be obtained by the use of enormous cylinders which should never find a place on ship-board. One thing is certain, although we have not nearly reached the maximum limit of size in our ships of war, we have in their engines; and we much more than doubt the possibility of forging a crank shaft, which would transmit 10,000-horse power when making but fifty revolutions per minute. Krupp's great steel ingot proves nothing to the contrary, our readers may rest assured. No one can fortell the dimensions of the ships we may see fit to build within the next ten years; and yet it is quite certain that any very great increase on what we have already accomplished, must entail a change in our engines, which those in authority never seem to contemplate.

We have already reminded our readers that a speed of twenty miles an hour has been realized by very many steam-ships; so many, indeed, that the velocity can scarcely be considered exceptional. A large proportion of our merchant steamers, although not coming within two or three knots per hour of this speed, are yet faster than our men-of-war, with one or two exceptions. It is urged, with much truth, that vessels built to fight, cannot compete with those built for speed. We will grant this to a certain extent; but even did we admit it in its entirety, it would still fail to prove a good argument for keeping speed were it now is, in the ships which we expect

to maintain the sovereignty of the seas. Our ships should be so engined that a speed of 16 knots would cease to be exceptional amongst them. It requires no very extensive alterations on existing arrangements to attain this end. The maximum amount of power to be obtained from a certain weight of machinery has never yet been determined, and we feel little hesitation in saying that 950 tons of it, as in the "Warrior," could easily develop, and transmit 10,000-horse power without risk. It is merely within certain limits, a question of piston speed, and the disposition and strength of materials. As to fuel, a 5,000-horse power engine should get on comfortably on 2·5 lb. of coal per horse-power per hour, and the fact that the engines of our Navy use nearly twice as much, proves nothing but their faulty construction. By the employment of simple engines, with small cylinders, and plenty of them; high pressure, say 50 lb. cut off at one-seventh of the stroke; good surface condensers and a speed of piston of, say 600 ft. per minute; superheating and steam-jacketing, there is no doubt that the consumption of fuel might be reduced by nearly one-half. And by driving the crank shaft by means of gearing, at a greater number of revolutions than the screw shaft, there would be no difficulty whatever in producing crank shafts large enough to transmit any power we pleased. The speed of our Navy is increasing; each ship we build is faster than the last, or intended to be so as a rule; and without due care we may arrive at a point where the marine engine builder will be unable to satisfy the demands made on him by the naval architect.

SUPERHEATED STEAM.

It is not very easy to say when the employment of steam, heated above the temperature due to its pressure, was first proposed as a means of economizing fuel. Like many other inventions or discoveries, it is claimed by several individuals, who certainly did not all hit on the idea simultaneously. The weight of evidence goes to show that superheated steam can trace its origin to America, where, some fifteen or twenty years ago, a Mr. Frost conducted some experiments on steam heated apart from water. These gave such remarkable results, that the attention of the Institute of Arts and Sciences at New York was called to the subject, which received further development at their hands. Subsequently, Dr. Haycraft, of Greenwich, made a number of experiments on what he termed "anhydrous steam." He tried his plans on an engine with a 9-in. cylinder and 3 ft. stroke with very considerable success. His apparatus burned out, however, from its faulty construction, and he appears to have abandoned further trials in disgust. Whatever the claims of rival inventors may be, it is certain that superheated steam was not brought prominently before the engineering world until 1856. In 1857, Mr. Penn's apparatus was fitted on board the "Valetta," with the immediate result of a saving of 20 per cent. in the consumption of fuel. Since then superheated steam has steadily advanced in public favour; indeed, it is far from improbable, that ere many years elapse, the employment of the principle will become all but universal in our steamships.

That a certain amount of economy must follow from the employment of superheated steam, is as plainly demonstrable as a mathematical proposition. What the *exact* amount may be, depends altogether on the construction of the engine and boiler, and the degree of expansion at which the engine is worked. It is almost needless to say that it can never arrive at the pitch which the first promoters of its application imagined. Frost and Haycraft considered it quite possible to expand steam sevenfold without raising its temperature much over 350 deg. That which is so obviously opposed to theory can never be correct in practice: the utmost saving of fuel which has yet been attained being 30 per cent., and this, be it remembered, only in cases where the boilers have been very defective, and failed to supply dry steam to the engines previously to the application of the superheater.

Steam not in contact with water, if quite dry, may be considered to expand in pretty nearly the same ratio, for successive increments of heat, as any of the fixed gases; or at the rate of 1-480th of its volume for each degree of Farenheit's thermometer. Thus, by heating it to 480 deg. above its own temperature, it would be doubled in volume, or, if confined, in pressure; but, it must be remembered, only at the loss of sufficient heat, to convert a body of water into as much steam as would be capable of performing more work, than that due to the increase in the volume, or pressure, of the steam superheated. The true sources of economy, are not be found in any such expansion—although that is of course useful, as far as it goes—but in the power superheating gives us of maintaining the temperature of the cylinder, valve chest, &c., at a very high point, and thus counteracting the cooling effects due to expansion; and also because all the free moisture or spray, which is suspended in a state of almost infinite subdivision in the steam, is vaporized in passing through the pipes of the superheater, and thus rendered available for the subsequent production of power in the cylinder. Thus, the best boilers show least gain from the employment of the principle when the engines do not work expansively, because they produce what is usually termed dry steam. Boilers of defective design, on the contrary, very frequently prime continuously; not sufficiently, it is true, to interfere with the working, or endanger the stability of the engines, but still quite enough to wasteful. Superheating invariably gives excellent results in such cases, both directly, in the saving of coal, and indirectly, by preventing the injurious action which dirty water always exerts on valve faces and pistons. The advantage to be derived in this way, however, is as nothing when compared with the facilities which superheated steam affords for carrying expansion to its maximum.

If we suppose steam of 60 lb. pressure admitted to a cylinder for one-sixth of the stroke, we shall find, that whereas its temperature on entrance was about 295 deg. Fahr., yet, on the completion of the stroke, it will, if the stroke is a long one, have fallen more than 70 degrees in consequence of its expansion. Be the cylinder ever so well protected outside, it being composed of comparatively thin metal, soon becomes cooled down to the temperature of the steam in contact with it. Thus, on the commencement of the next stroke, the steam, on entering, is at once chilled and condensed by contact with a metal surface nearly—from one source or another—100 degrees cooler than itself. The result is that expansion, under such circumstances, is a source of waste, instead of economy, because, had the steam been kept to full pressure nearly through the stroke, the cylinder would never have had time to cool sufficiently to do much harm. The fact of this loss of heat taking place in expanding, unless special provision is made to prevent it, is beautifully illustrated in Cornish engines without jackets, the pistons of which, though perfectly tight when near the bottom of the cylinder, are frequently found to blow through at the commencement of the down stroke, from the fact that the upper part of the cylinder is permanently larger in diameter, owing to its higher temperature, than it is near the bottom, where only cooler steam reaches it.

"Lagging" a cylinder is only a negative remedy; a means of prevention, not of cure. Cylinders waste heat inside as well as out, by radiation into the condenser, and the reduction of temperature due to expansion. Felt and boards cannot possibly restore this; and unless special means are provided for doing so, it is simply hopeless to expect economy. Fortunately, we are not confined to one arrangement. Four different systems of "cylinder heating," as we may term it, are more or less employed. These are: the use of a jacket, supplied with saturated or common steam; or with heated air; or with superheated steam; or the use of superheated steam, to work the engine, and of all the plans yet adopted, this seems to be almost beyond comparison the best. Not only does it provide a supply of pure gaseous steam, free from moisture, but it heats perforce every particle of metal with which it comes in contact, so that not the cylinder alone, but the lids and piston are raised directly to the same temperature. The surface presented by a large piston is very considerable, and it is, of course, beyond the power of any jacket to provide for the condensation which it may occasion if not kept up to the full initial heat of the steam in contact with it. But the principal advantage possessed by superheated steam, is the beautiful simplicity of all the arrangements connected with it. As now constructed, the necessary apparatus can be provided for about £2 per horse-power nominal. Experience proves that tubes last well, that leakages are rare, and that the expenses for repairs are small. When employed, as—like almost everything else—it should be in moderation, no danger exists of injury to valve faces or cylinders. A temperature of 300 to 360 deg. seems most suitable; and a heat such as this certainly cannot injure the most delicate surface met with in a valve or a piston. By its use, simple lagging may act as a very efficient substitute for the costly and heavy jacket. A little more time, and the experience which follows as a matter of course, will, we believe, place the superheater in a position which will entitle it to be considered indispensable to every steam-engine which pretends to even a moderate amount of economy.

THE LATE MR. JOSHUA FIELD.

With the deepest regret we record the death of Mr. Joshua Field, F.R.S., of the firm of Maudslay and Field, engineers. Mr. Field expired at his residence, Balham-hill, on the morning of the 11th instant; the immediate cause of his death being dropsy supervening on an attack of gout, his illness extending altogether over a period of four months. The deceased gentleman was in the 77th year of his age; and up to the commencement of the disease which has terminated so unfortunately, he possessed in the fullest degree all his powers of mind and body.

His death is too recent to enable us to give as yet as full a sketch of Mr. Field's life as we could wish. Of such men, data exist, and facts are known, which lie dormant, and almost forgotten, until time brings them to light.

The Institution of Civil Engineers owes its

existence to six young men—H. R. Palmer, Joshua Field, William Maudslay, J. Jones, C. Collinge, and James Ashwell—who founded it in 1817. Mr. Field was one of the earliest Vice-Presidents, holding that office until the 18th of January, 1848, when he was elected President, being the first mechanical engineer who filled the chair. The admirable manner in which he fulfilled his responsible duties is too well known to need comment.

To Mr. Field in connection with Mr. Maudslay, may be traced, in a great degree, the origin of ocean steam navigation. The engines put by these gentlemen on board the "Great Western" in March, 1838, were so completely successful that they long served as a model for other builders. On Sunday, the 8th of April, 1838, she started on her first voyage from Bristol with seven passengers, and 50 tons of goods, and reached New York on Monday the 23rd of April, thus accomplishing the 3,000 miles in 13 days 10 hours.

Mr. Field was not more respected for his talents as an engineer, than loved and esteemed for his amiable qualities and fine disposition. To know him as a man of science, was an honour; to be classed by him as a friend, was something, beside which even honour sank into insignifigance. His death has been a blow deeply felt by nearly every member of the profession.

Mr. Field was interred at Norwood Cemetery on Tuesday, the 18th inst. The funeral cortege consisted of nine mourning coaches, containing the relatives and more immediate friends of the deceased, and fourteen private carriages. At the cemetery gates were assembled a considerable number of workmen, principally elderly men, who have been engaged at the works for a long period.

The Institution of Civil Engineers was represented by Mr. J. Simpson (Past President), Mr. C. H. Gregory (Vice-President), Mr. Penn, Mr. Lloyd, Mr. Humphrys, Mr. Crampton, Mr. E. A. Cowper, Mr. Bryan Donkin, Mr. R. C. May, Mr. H. Maudslay, Mr. C. Sells, Mr. Joseph Freeman, Mr. Redman, Mr. Collins, Mr. P. W. Barlow, with Mr. James Forrest, the Secretary. There were also present Mr. Appold, Mr. Ravenhill, and many other engineers and men of science.

PRESERVATION OF IRON-PLATED AND OTHER SHIPS.

SIR,—Having noticed in several publications an account of the patent of Mr. Jean Pierre Jouvin for "preserving iron-plated and other vessels and metallic articles from oxidation and preventing ships bottoms from fouling," I think it advisable to address these few lines to you, not to discuss this important invention, but to lay before your readers a few facts which I have observed during the last few years, in the course of some researches which Mr. Richard Johnson and I have made on this most interesting subject.

In the year 1858, Mr. Johnson and I took plates of iron and covered 1-20th, 1-40th, 1-80th, and 1-100th of one surface with zinc plates, which we tied close to the iron plates, and then immersed them in soft and sea water. We examined these plates at the end of one, two, and three months, and finding that the zinc had exercised a very remarkable preservative effect on the iron, we brought the matter under the notice of Mr. Hewitson, shipbuilder on the Tees, who promised to institute a series of experiments in connection with his iron ships, to ascertain whether the results we had obtained in my laboratory would be confirmed on a practical scale, but this gentleman soon after fell ill, and consequently died. In the meantime, it occurred to us that the most practical mode of applying zinc for the preservation of iron ships would be to use galvanized iron, and we therefore instituted a series of experiments to ascertain the extent to which protection would be thus afforded.

Plates of iron 3 in. square were attached with great care to pieces of oak of the same extent of surface, and immersed in soft and sea water. Similar plates of galvanized iron were also similarly attached to pieces of oak and immersed in soft and sea water, and the following were the results observed after two months immersion—viz., from January 3 to March 5, 1862:—

		Loss by corrosion. 1st series of experiments. Grammes.		2nd series. Grammes.
Pieces of wood and iron.	In distilled water	1·230	...	1·230
	In salt water ...	2·400	...	2·380
Pieces of wood & galvanized iron.	In distilled water	0·100	...	0·125
	In salt water ...	0·095	...	0·090

We were anxious to know whether a prolongation of the experiment would continue to show the same comparison, and we therefore again immersed the iron plates in distilled and sea water until May, 1863, when the iron plates were again removed from the pieces of oak, carefully washed and dried, and weighed.

		Loss by corrosion. 1st series. Grammes.		2nd series. Grammes.
Pieces of wood and iron.	In distilled water	1·700	...	1·550
	In salt water ...	4·320	...	4·280
Pieces of wood & galvanized iron.	In distilled water	0·500	...	0·830
	In salt water ...	0·780	...	1·220

These results leave no doubt of the great protective power exercised by zinc against the corrosive action of water, and especially of sea water upon iron plates, I therefore think that all iron used in shipbuilding should be galvanized, and as this operation is now performed with such facility and so little expense, I cannot see any commercial objection to its general adoption. There is a further argument in the favour of this course in the fact that it is not the loss of iron only that is in question, important as that is, but there is also the wood which, especially in the case of oak, is rapidly deteriorated by the presence of oxide of iron, upon which the gallic and tannic acids of oak exercise a powerful action, and thus cause the wood to enter into a state of rapid decay or emaracausis, well known to shipbuilders.

Mr. Johnson and I also deemed it advisable to ascertain whether the zinc was liable to be removed from the surface of the iron by intense friction, and to decide this point we made the following experiments:—Large bolts, 1 ft. long and ½ in. in diameter, were driven into solid blocks of oak by a sledge hammer. The blocks were then opened, and the bolts were found to be not in the slightest degree uncoated. Another series of experiments was made, consisting of driving screws of the same diameter as the bolts into solid blocks of oak, and the same satisfactory results were observed.

I am, &c.,
F. CRACE CALVERT.

NEW RESEARCHES UPON THE PRESERVATION OF BUILDING MATERIALS.

THE following Paper, by Mr. Fred. Kuhlman, is abstracted from the *Comptes Rendus de l'Academie des Sciences*:—

In my previous researches upon the hardening of stones, and the preservation of building materials, I had endeavoured to impregnate the porous stones, and the renderings in plaster or lime, with some mineral substance capable of combining with those bodies or those coatings. Amongst the chemical combinations that were unattackable, and susceptible of augmenting the hardness, the substance that seemed to me to merit the preference was the silicate of potash. But, because this agent is of general efficacy, it by no means follows that there may not be some circumstances in which its action is partly paralyzed by causes depending upon the nature of the materials, or of the conditions in which they may be placed at the moment of their application.

It is thus experience has shown that when the silicatization is applied to ancient constructions, its efficacy may be unsatisfactory, if there had previously existed in the walls a commencement of decay, developed under the influence of ammoniacal exhalations and constant damp. In such cases, the exterior coats of the walls and of the renderings, although hardened by the silicatization, are thrown off, and finish by detaching themselves by the formation of nitrous salts, and the decay continues to make progress. The expedient that I have found to answer best in those cases, for brick walls in particular, consists in removing entirely the coating and the joints of the work beneath in mortar, and, after having warmed the place by means of a moveable brazier, to cause them to absorb, by means of a brush, or by casting it upon the work to be protected, some pitch, arising from the distillation of coal, and applied as warm as possible. After cooling, the parts of the wall covered by the pitch can be recoated with a new rendering of plaster which will adhere perfectly well, and to which the silicatization will ensure the best conditions of durability and unalterability. Gas-tar has become of very general use in the towns of the north of France, to protect the basements of the houses from the effects of the external damp; but they have not yet been able to prevent the damp from rising in the interior by the effect of the capillarity. In my factory of chemical products I make a more general use of this tar still. I apply it hot upon all the exterior walls of the ovens, for decomposing salts, burning pyrites, concentrating sulphuric acid, &c., and I impregnate, by immersion in boiling tar, the tiles destined to the covering of roofs, particularly of those where there are any acid vapours produced.

In England, in the soda factories, where the hydrochloric acid is generally condensed in chimneys, or towers containing coke kept constantly wetted by a stream of water, the flagging which serves as a base to these towers, when it is of a porus nature, is immersed in hot tar before it is laid down. In other circumstances, the tar is used to colour tiles made of porous clay for general use.

If, in certain cases, the application of mineral waters to the preservation of walls would be difficult, it would not be impossible to employ organic matters less exposed to alterations than the resins and bitumens which the ancients had employed as the basis of the preparations for preserving the dead bodies, and which, by their unalterability, represent, in a similar manner to coal, a period of cessation in the decay of organic substances. The efficiency of coatings of a greasy or resinous nature, even though superficial, against the destructive action of the sea air, bringing with it sea water, was proved to me in the course of last summer, when I had occasion to examine the rapid progress of decay that was taking place in the porous sandstone of the chapel of St. Eugenie, on the borders of the sea, at Biarritz. The stones of this chapel, whose construction only dates from the year 1858, are profoundly corroded on all the points exposed to the wind, and I observed this peculiarity in the stones, which, before being put in place, were marked with oil colour, in black, that the parts covered with the colour were protected against alteration, so that the numbers now stand out in relief with great distinctness. The example of these figures in relief, in which the preservation of the stone was assured by the merely superficial application of the greasy or resinous matters, made me think that, in a

number of cases, the bitumens and resins might be made to play a very useful part in the preservation of buildings or sculptured decorations, if, instead of applying them to the surface, they were made to penetrate into the interior of the stones without decomposing their surface, as I had recommended should be done with the applications of mineral solutions.

I have made numerous essays to assure myself of the possibility of this penetration, by employing pitch derived from the distillation of coal-tar; it is a matter easily met with in commerce, and whose price (4 or 5 francs the 100 kilogrammes) is not high, and which serves now-a-days only for the manufacture of the small bricks made from the waste coal. I cause to be boiled in it, without any other pressure than that of the atmosphere, stones, carved or rough; bricks; objects made in clay, or simply dried in the open air which are able to form a pottery, without being burnt or varnished. These are boiled in vessels of cast or wrought iron, and I thus obtain a penetration of the pitch to a great depth, and with that a considerable degree of hardness and a perfect impermeability. These properties would render such materials essentially fitted for the construction of the foundations of houses, for the coverings of walls, for hydraulic works, and particularly to those exposed to the sea air. I have also formed with hot tar and some mineral substances in powder, pastes that are more or less fusible under the effects of heat, according as they may contain in their composition more or less tar, and which are susceptible of being moulded, with or without compression, into bricks, tiles, and into architectural ornaments of every kind. The matter whose incorporation has afforded the best results is, the oxide of iron resulting from the combustion of the pyrites, and which, when mixed with a quarter of its weight of tar, yields a paste which presents a hardness and a sonority that are very remarkable.

I have no necessity to dwell upon the frequent applications which such pastes as are impermeable would admit of, in building, in hydraulic works, especially in those washed by the sea, in which experience has shown that all cements, sooner or later, suffer disintegration. These materials, cemented together with melting tar or put together in the same manner that the constructions are formed of pounded clay (*en pise*), would make monoliths whose durability ought to be tried in our harbours.

The application of the silicious dissolutions upon plaster was that which yielded the most unsatisfactory results, because at the moment of contact there was an exchange of acid, and the production of gelatinous silica, which formed on the surface of the plaster an impermeable coating, which, in its turn, prevented the penetration of the silica to the centre of the mass. This does not occur with the calcareous stones, nor even with alabaster, in which the isolation of the silica, or its combination with the calcareous base, can take place more slowly. The silicious coatings produced upon plaster casts by the silicate of potash, present, moreover, the disadvantage, when they are produced by strong dissolutions, of cracking, and detaching in scales. The application of bituminous substances to preserving plaster then attracted the whole of my attention; and I am happy to be able to say that the chemical composition of the plaster, instead of being an obstacle, as in the case of the silication, to the hardening and impermeability of the body, on the contrary, tended to realize those results.

Indeed, not only does the melting tar penetrate the plaster by the aid of its great porosity, in the same manner in which it filters between the molecules of calcareous or friable sandstones, and thus destroys their permeability, but it also replaces the water of hydration in proportion as the latter escapes, when the objects that are cast in plaster are plunged into a bath of melted tar, whose temperature may be 600 deg. or 700 deg. Fahr., although the water of hydration escapes at 230 deg. or 248 deg. Fahr. The effect of the expulsion of the water of hydration under the circumstances, is easily understood; but that which it was hardly permitted to be hoped, and whose reaction is the most interesting in a scientific point of view is, that the objects thus cast in plaster should retain, without change of form, the outlines they had received in the moulds, and that the substitution of the tar for the water should be produced to great depths from the surface, when the ornaments, or the statues in plaster, remained a sufficiently long time in the bath of boiling tar. I obtained a very striking proof of this molecular substitution by the transformation of crystals of the natural sulphate of lime into a black shining mass, having the same crystalline form, and in which the water of crystallization had been changed, and the tar substituted. This constituted a singular instance of pseudo-morphism.

I have shown, in a work published upon ethers in 1841, that alcohol and sulphuric ether could form, like water, combinations which were crystallizable with certain acids, and anhydrous chlorides; but it is difficult to admit that the same thing should happen with plaster, for it is not only the tar, which, without altering the crystalline form of the gypsum, can substitute itself for the water of crystallization, but also of several other fatty or resinous matters; stearic acid is of this number. When, instead of melting the stearic acid in a sand-bath, as it is the custom to do, figures in plaster are moulded and impregnated superficially with this fatty acid, the bath of stearic acid is heated to 330 deg. or 400 deg. Fahr., it is easy to see that the water of hydration is expelled by a great bubbling that is produced by the passage of the water through the reacting liquid. It is a question, then, in my opinion, of a simple infiltration, determined by the vacuum that the water of filtration leaves in proportion to the elimination thereof, of an infiltration or intimate penetration, which takes place under such circumstances that the crystalline body should not cease to retain its form, and should acquire a great degree of hardness, which would not be the case when the water of crystallization is driven off by heat alone. It must be the case that this penetration, although the result of an action purely physical, must be very intimate; for washings with ether and benzine, repeated frequently, succeed in detaching the tar from the transformed crystals, however well pulverized they may be.

My manner of explaining the phenomenon observed seems the more admissible, because the number of the substances that can thus substitute themselves for water is considerable; but care must be taken, as the chemical action of all the substances upon the plaster is not the same, and they cannot be substituted indifferently to the dehydrized plaster at a temperature sufficient to drive off the water of crystallization, in the same manner as tar, stearic acid, oil, &c. In order to effect this substitution, it is necessary that the liquid in question should be able to *moisten* the plaster; for I have found it to be impossible to substitute sulphur, or mercury, for the water of crystallization.

I have already shown, in a work upon épigénisis, that there were numerous instances known in which crystallized bodies preserved their form, although they had lost one or more of their constituent principles: it is thus that I have converted the binoxide of manganese into the protoxide, and into an intermediate oxide; the oxide of copper, and the natural carbonate of lead, into copper and lead; the formiate of lead into the sulphate; all the while preserving to the new bodies the crystalline forms of the bodies which gave rise to them, with simple modifications in their porosity. It is in this way that I recently showed that crystals of acedote can be transformed into hausmannite without changing their form. However this may be, the substitution of tar for the water of hydration in moulded plaster, in gypseous alabaster, and in isolated crystals of the sulphate of lime, will fix the attention of geologists and crystallographers; and it is not impossible that a deeper study of this phenomenon may lead to some new observations that may throw some light upon the transformations to be met with in the history of the globe.

Under any circumstances, I hope that the interest the Academy may attach to these observations may be increased by the great resources that the facts I have recorded place at our disposal, for the increase of our houses in healthiness, and the improvement of their decoration. They will allow plaster moulded, and alabaster carved, to be used as ornaments sculptured, impervious to wet, and unattackable by the frost, and without any of the defects that now exclude plaster from the decoration of our houses and public buildings.

M. Payen cited, in confirmation of the observations of M. Kuhlmann, some facts that demonstrated the remarkable influence that thickened tar and fatty substances had upon the resistance and the impermeability of building materials. Some great examples had been given in this respect of immersing in melted tar, at about 400 deg. Fahr., some soft bricks that had been very successfully used in buildings destined to receive the chlorine gas when cemented with asphalte; some soft sandstones of Fontainbleau had been considerably hardened by this process; Champy, in 1813, had also preserved wood by injecting tar, in a similar manner, into the interstices and the channels of the wood.

On the occasion of the meeting of the Academy of Sciences on the 22nd of June, M. Frederick Kuhlmann read a second communication upon the same subject, in which he said that—

My opinion upon the part which I assigned to the tar, when it had penetrated the moulded plaster, and had been substituted for its water of hydration, has been confirmed by the following observations:—

When the water of hydration of the mineral matters can only be displaced at high temperatures, or when these matters are anhydrous, the tar infiltrates only into the fissures they present. I have proved this fact upon crystals of quartz, Iceland spar, rock salt, and upon other anhydrous minerals unattackable at the degree of temperature at which the operation has been effected. When the crystals are fibrous and manifestly porous, like those of an agonite, stalactite, &c., the penetration is more intimate. I ought to mention on this occasion that a topaz and a rock crystal, the fissures of which had been penetrated by the tar, presented, when looked at by transparency upon the thin edge of the coat of tar, a colour of sombre garnet, analogous to that which is presented by smoked quartz, and sufficiently near that which glass melted under the influence of smoke would do, and which disappears by the addition of a little saltpetre. It must, however, be admitted that it is possible that this colour may be owing to the properties of the tar, when it is in the state of a very thin layer.

Upon a specimen of opal, submitted for a certain time to the action of boiling tar, I have proved that, independently of the infiltration of the tar through the fissures, the little water this stone loses is proved by a tint of smoked blue, a tint exactly like that of a variety of the opal of Mexico, which is to be found in the Museum of the School of Mines. This colouration of the opal merits the attention of mineralogists, for it was the paste itself which had been uniformly impregnated with bitumen, and had assumed colours which might be useful to jewellers. It seems to me, also, to throw some light upon the bituminous substances that are sometimes found in rock crystals. Gun-flints yielded similar results. When the flint is embedded in a pudding-stone composed of silicious materials, the agglutinating material impregnates itself easily with the tar, whilst the colour of the flint changes slightly.

When certain marbles which are very open in their grain, and are marked with decided veins, are submitted to the action of melting tar or other resinous or fatty substances, such as the onyx, &c., phenomena precisely analogous occur. The modifications of colour, and the great consolidation that the marbles can derive from this operation, may be well employed in decoration.

It is not only the loss of the water of hydration that facilitates the penetration of the tar, or of the other resinous substances, into the mineral

matters, but it may be also the loss of the other constituent part of those matters. Thus, malachite, subjected to the action of boiling tar to a graduated temperature, is transformed—firstly, into a black matter, in which the copper rests as an oxide, and which retains the ribbed and filamentary structure of the malachite. But the malachite, as also the azurite, are reduced, and present themselves in the metallic state when the temperature attains 520 deg. or 570 deg. Fahr. Copper which has been arseniated becomes fused at the same temperature, and gives off the arsenic that is carried away by the vapours of the tar. The carbonate of lead is reduced at still lower temperatures. One of the most clear results that I have obtained has been in the tranformation, by means of the boiling tar, of the binoxide of manganese into the protoxide, without any change in the crystalline form of the binoxide, the tar having taken the place of the oxygen driven off for the benefit of the reducing body. The oxide of manganese, fater the reaction, does not give any trace of chlorine by its contact with hydrochloric acid.

In all these reactions, whether the tar displaces the water, or some other principle constitutin g the minerals, or may intervene by penetrating only the fissures of the matters, it is important that the temperature of the tar should be gradually raised, so as not to produce a disruption of the bodies submitted to its action. This precaution is particularly necessary, when it is required to submit to the melting tar articles in clay only dried in the air or in stoves, and which it may be desired to convert, in this manner, into impermeable pottery. When this heat is applied too briskly, the minerals and the clays are exposed to crack and to fly before the tar has had time to penetrate them.

By using the precaution that I have just indicated, I have obtained, with moulded clay and dried, pottery which, independently of the very great economy of its production, is recommendable on account of its impermeability, its hardness, and its great resistance to acids. The application of this pottery to drain-pipes, tiles (both roofing and flooring), and an infinity of other subjects that usually require economy of manufacture, seems to me susceptible of great extension, if I may judge by the results of the first trials made with a view to the success of these experiments, and which I have had the honour to submit to the Academy.

In a subsequent part of the evening some observations by M. Robinet were read, confirmatory of the remarks made by M. Kuhlmann, upon the preservative effects of the oil-colour inscriptions on the buildings of St. Eugenie, at Biarritz, and he cited other instances in proof of the great effects thus produced. — *The Journal of Gas Lighting.*

INSTITUTION OF CIVIL ENGINEERS.

SUBJECTS FOR PREMIUMS.

Session 1863-64.

The Council of the Institution of Civil Engineers invite communications on the subjects comprised in the following list, as well as upon others; such as 1, Authentic Details of the Progress of any Work in Civil Engineering, as far as absolutely executed (Smeaton's Account of the Eddystone Lighthouse may be taken as an example); 2, Descriptions of Engines and Machines of various kinds; or 3, Practical Essays on Subjects connected with Engineering, as, for instance, Metallurgy. For approved Original Communications on these, or other subjects, the Council will be prepared to award the Premiums arising out of special funds devoted for the purpose.

1. On the Decay of Materials in Tropical Climates, and the methods employed for arresting and preventing it.
2. On the Theory of Metal and Timber Arches.
3. On the Theory and details of Construction of Wrought Iron Girder Bridges.
4. On Land-slips, with the best means of preventing, or arresting them, with examples.
5. On the Pressure of Earth on Tunnels, and the conditions which limit its amount.
6. On the Theory and Practice of Artesian Well-boring, and of sinking large shafts, as now practised on the Continent.
7. On the results of contrivances for facilitating the Driving of Tunnels, or Drifts in Rock.
8. On the Principles to be observed in Laying-out lines of Railway through mountainous countries, with examples of their application in the Alps, the Pyrenees, the Indian Ghauts, the Rocky Mountains of America, and similar cases.
9. On the best means of preserving Railways in Alpine countries from interruptions from snow.
10. On the Results of recent experience in Iron Permanent Way.
11. On the Principles to be observed in the designing and arrangement of Terminal and other Railway Stations, Repairing Shops, Engine-sheds, &c., with reference to the traffic and the rolling stock.
12. On Railway Ferries, or the Transmission of Railway Trains entire across Rivers, Estuaries, &c.
13. On Locomotive Engines for ascending Steep Inclines, especially when in combination with sharp curves, on Railways.
14. On the Working of Locomotive Engines in Long Tunnels, with frequent stations.
15. On the Results of the Application of Giffard's Injector to the Boilers of Locomotive and other Engines.
16. On the Working Expenses of Railways, and the influence on these of the original design and construction.
17. On the Results of a series of observations on the Flow of Water from the Ground, in any large district; with accurately-recorded Rain-Gauge Registries, in the same locality, for a period of not less than twelve months.
18. On the Construction of Catch-water Reservoirs in Mountain Districts, for the supply of Towns, or for manufacturing purposes.
19. Accounts of existing Water-works; including the source of supply, a description of the different modes of collecting and filtering, the distribution throughout the streets of Towns, and the general practical results.
20. On the Best Means of Improving the Water Supply of the Metropolis.
21. On the Structural Details, and the Results in Use, of Apparatus for the Filtration of large volumes of water.
22. On the Drainage and Sewerage of large Towns; exemplified by accounts of the systems at present pursued, with regard to the level and position of the outfall, the form, dimensions, and material of the sewers, the prevention of emanations from them, the arrangements for connecting the house drains with the public sewers, the best means of limiting the contamination of rivers from the sewage discharged into them, and the disposal of the sewage, whether in a liquid form, as irrigation, or in a solid form, after deodorisation.
23. On the Results of the Employment of Steam Power on Canals, and of other measures for the Improvement of Canals as a means of conveyance for heavy traffic.
24. On Iron Paving, and a comparison of the Results attained by it, and by stone block paving, &c.
25. A History of any Fresh Water Channel, Tidal River, or Estuary—accompanied by plans and longitudinal and cross sections—including notices of any works which may have been executed upon it, and of the effects of the works; particularly of the relative value of Tidal and Fresh Water, and of the effect of Enclosures from the Tidal Area upon the general *regime*, of Sluicing where applied to the improvement of the entrance or the removal of a Bar, and of Groynes, or Parallel Training Walls. Also, of Dredging, with a description of the Machinery employed, and the cost of raising and depositing the material.
26. On the Results of a Series of Observations, illustrative of the modifications which the tidal wave undergoes in its passage up and down a river, or estuary.
27. On the Construction of Tidal, or other Dams, in a constant or variable depth of water; and on the use of wrought iron in their construction.
28. A History of any Harbour, or Dock, including the reasons for selecting the site, the mode of construction adopted, and the subsidiary works for the convenience of shipping, and for commercial purposes, with the cost, &c.
29. On Graving Docks and mechanical arrangements having a similar object, with the conditions determining their relative applicability in particular cases, as dependent on the rise of tide, the depth of water, and other circumstances.
30. On the arrangement and Construction of Floating Landing Stages, for passenger and other traffic, with existing examples.
31. On the different systems of Swing, Lifting, and other opening Bridges, with existing examples.
32. On the Construction of Lighthouses, their Machinery and Lighting Apparatus; with notices of the methods in use for distinguishing the different Lights.
33. On the Measure of Resistance to Steam Vessels at high Velocities.
34. On the Results of the use of Tubular Boilers, and of Steam at an increased pressure, with, or without superheating for Marine Engines, noticing particularly the difference in weight and in speed, in proportion to the Horse Power and the Tonnage.
35. On the relative advantages of the Principle of Expansion, as applied in the Single long-stroke Cylinder Engine, in the Double Cylinder Engine, and in the Three Cylinder Engine; and on the adaptation of the two latter to marine purposes.
36. On the Principles and Varieties of Construction of Blast Engines, with British and Foreign examples.
37. On the best description of Steam Fire Engines, and their power and efficiency, as compared with ordinary hand Fire Engines.
38. On the construction of, and the comparative duty performed by, modern Pumping Engines for raising Water, for the supply of Towns, or for the Drainage of Mines; noticing in the latter case, the depth and length of the underground workings, the height of the surface above the sea, the geological formation, the contiguity of streams, &c.
39. On Turbines and other Water Mo tors of a similar character; and their construction and performance, in comparison with Water-wheels.
40. On the present systems of Smelting Iron Ores; and on the conversion of cast iron into the malleable state, and of the manufacture of iron generally, comprising the distribution and management of Iron Works.
41. On the Manufacture of Iron for Rails and Wheel Tyres, having special reference to the increased capability of resisting lamination and abrasion; and accounts of the Machinery required for rolling heavy Rails, Shafts, and bars of Iron of large sectional area.
42. On the Manufacture of large masses of Iron for the purposes of Warfare, as Armour Plates, &c.
43. On the Construction of Rifled and Breech-loading Artillery; and on the Initial Velocity, Range, and Penetration of Rifled Projectiles, and the influence of Atmospheric Resistance.
44. On the Use of Steel Bars and Plates in Engine-work and Machinery, for Boilers and for Shipbuilding, as well as for Bridges.
45. On the Use of Steel in the Construction of Locomotive Engines, especially with reference to durability and the cost of repairs, in tyres and cranked axles, as compared with Iron of acknowledged good quality.
46. On the Bessemer and other processes of Steel-making; on the present state of the Steel Manufacture on the Continent of Europe; and on the employment of castings in Steel for Railway Wheels and other objects.
47. On the safe working strength of Iron and Steel, including the results of experiments on the Elastic Limit of long bars of Iron, and on the rate of decay by rusting, &c., and under prolonged strains.
48. On the Transmission of Electrical Signals through Submarine Cables.
49. On the present relative position of English and Continental Engineering Manufactories, especially with reference to their comparative positions in respect of the cost, and the character of the work produced.
50. Memoirs and accounts of the Works and Inventions of any of the following Engineers:—Sir Hugh Middleton, Arthur Woolf, Jonathan Hornblower, Richard Trevithick, William Murdoch (of Soho), Alexander Nimmo, and John Rennie.

Original Papers, Reports, or designs of these, or other eminent individuals, are particularly valuable for the Library of the Institution.

The competition for Premiums is not confined to Members, or Associates of the Institution, but is equally open to all persons, whether natives, or foreigners.

The Council will not consider themselves bound to award any Premium, should the Communication not be of adequate merit, but they will award more than one Premium, should there be several communications on the same subject deserving this mark of distinction.

The Communications must be forwarded, on or before the 1st of January, 1864, to the house of the Institution, No. 25, Great George-street, Westminster, S.W., where copies of this paper, and any further information may be obtained.

Charles Manby, Hon. Sec.
James Forrest, Sec.

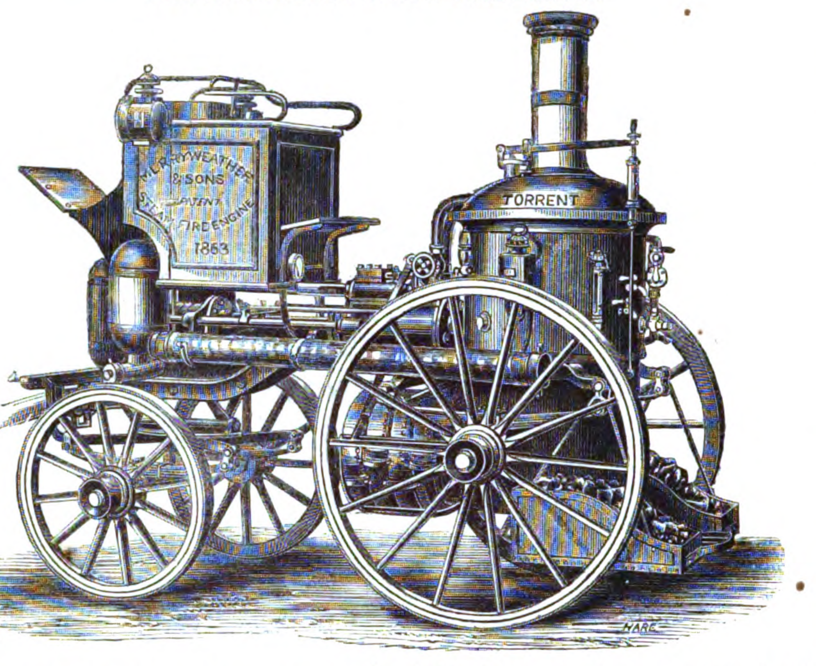
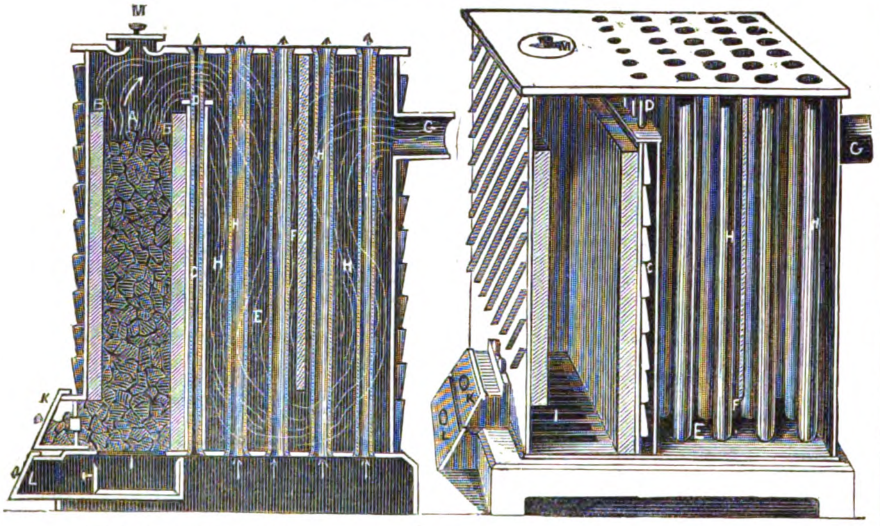
MERRYWEATHER'S STEAM FIRE-ENGINE.



MERRYWEATHER'S STEAM FIRE-ENGINE.

WE give above a perspective view of Messrs. Merryweather and Field's small steam fire-engine, which we have already fully described in the MECHANICS' MAGAZINE of July 27. The construction of the boiler is perhaps the most remarkable feature in the engines built by this firm; and to it in a great measure may be ascribed their success at the late trials. Both the large and small engines have the same boilers, and are externally very similar in appearance, the chief differences consisting in the arrangement of the cylinders, pumps, and valve gear.

RIDDELL'S STOVES.



RIDDELL'S STOVES.

THE following improvements in stoves have been patented by Mr. J. H. Riddell, of 155, Cheapside :—

This invention relates to stoves, usually called hot-air or slow-combustion stoves, and consists in an arrangement by which the heated or radiating surfaces of such stoves are so increased as to cause a large volume of air to be rapidly heated to a comparatively low temperature, instead of, as in former arrangements, heating a small volume of air to a high temperature, and which heated air can only be used after being mixed with a large volume of cold air. The invention is carried into effect by forming a fire-box of cast iron or other material, which may be lined with fire-bricks, and which fire-box is connected with one or more chambers, through which the heated products of combustion pass on their way to the chimney or vent; such chambers being fitted with metal or other tubes, either in a vertical or sloping position, through which tubes a current of air is constantly and rapidly flowing, and which air becomes heated in its passage and prepared for warming and ventilating churches, or large halls, or buildings.

Fig. 1 is a perspective view of the stove, with one side removed to show the internal arrangement; and fig. 2 is a vertical section, with the ventilating or respiratory tubes or pipes distinctly shown; the direction of the currents of warmed air being also indicated by arrows.

A is the fire-box; B, the fire-brick lining of the fire-box; C, a chamber formed at the back of the fire-box, through which air passes, and being heated as it ascends ultimately escapes through the pipes D. These pipes also act as a grating or check to prevent the fuel passing from the fire-box to the smoke chamber. E, E, is the smoke-box or chamber of the stove, which is divided by a curtain F, which descends to within a few inches of the base plate of the stove; G, the smoke nozzle, through which the smoke passes to the chimney; H, H, H, pipes of metal or earthenware, which pass through the smoke-box of the stove, and are open at the top and at the bottom, and fitted over corresponding openings in the top and bottom plates of the stove; I, the fire-bars; K, the upper mouthpiece, through which clinkers or cinders may be removed from the fire-box; L, the lower mouthpiece or regulating door, through which ashes are removed, and the air admitted to support combustion; M, the feed door or lid, through which the stove is supplied with fuel. This lid drops into a groove in the cover of the stove, which is filled with sand, and secures an air-tight joint, preventing the escape of any of the products of combustion, except to the chimney. When the stove is in action, the pipes H, H, H, become heated, and a current of cold air entering at their lower end passes through them, and as it becomes warmed by abstracting heat from the hot pipes it rises, and ultimately escapes from the upper orifice of the tube into the chamber to be warmed; and it may be observed, that the air does not become dried or over-heated in passing through these tubes, as it obeys a natural law, and the hotter the pipes become the more rapidly does the air pass through them and escape. The external radiating surface of the stove may also be increased by feathers or corrugations being cast upon it. There are thus two distinct currents passing through the stove—one consisting of smoke and the heated products of combustion passing from the fire-box A through the front chamber of the smoke-box E, then under the curtain F, up through the back chamber of the smoke-box E, and ultimately passing through the smoke-nozzle G to the chimney; the second current is composed of atmospheric air, which entering the respiratory or ventilating tubes at the bottom of the stove becomes warmed in its passage, and escapes through the top of the tubes into the chamber to be warmed.

COAL-CUTTING BY MACHINERY.

AN improved coal-cutting machine, invented by Messrs. Robert Ridley and Jones, has just been completed at Mr. Middleton's factory, in Loman-street, S.; and on Saturday last we took the opportunity of inspecting it at work, the cutting upon this occasion being made into a solid block of freestone. The size of the machine is about equal to that of a full-sized trunk, being about 3 ft. long, 1½ ft. wide, and 2 ft. high; it has flanged wheels, to run on the ordinary pit tramway, and weighs about ½ ton. Motion is given to it by a 6-inch cylinder high-pressure engine, the pick being connected with the end of the piston-rod; and by varying the mode of connecting, the blow may be given either right-handed or left-handed. There is an arrangement for regulating the depth and force of the blow, precisely similar to that used in the steam-hammer; and as the attendant has his hand constantly upon this regulator while the machine is at work, the precision obtained is fully equal to anything that could be obtained by hand labour. Indeed, the collier directing the machine must use precisely the same amount of judgment as if he were using an ordinary pick; the principal difference being that he is enabled to strike five blows with the machine for one blow with the hand.

With respect to the efficiency of machines upon which this is considered to be an improvement, we cannot do better than state the results recorded by Messrs Daglish and Wood, in their paper read before the North of England Institute of Engineers, as obtained in actual practice with Messrs. Donisthorpe, Firth, and Ridley's machine, at the West Ardsley Company's Balaclava Colliery, near Leeds. Working long wall, a kirving 35 yards long, and 37 in. deep, was made in 2 hours 45 minutes, including all stoppages; and in a subsequent experiment, a kirving 43½ yards long and 37½ in. deep was made in 2 hours 37 minutes, so that at the mean practicable working speed it would appear that a yard can be cut in about 4 minutes. A kirving at the depth mentioned would be made at three cuts; the first going in about 16 in., and the two subsequent cuts about 10 or 11 in. each. In these experiments the speed of the blows averaged about 40 per minute, but the machine just completed gave 15 in 10 seconds, so that it is probable 60 per minute could readily be given in the pit. As compressed air is used

instead of steam, the difficulties which have prevented the success of several of the machines which have been introduced do not exist, whilst the price of the machine being considerably under £100, and its liability to get out of order is very small, it cannot fail to be very generally adopted as soon as the amount of economy which it effects becomes generally known.—*Mining Journal.*

THE "SKIN RESISTANCE" OF SHIPS.

Although the laws of fluid friction would appear to have been well ascertained, the absolute frictional or skin resistance of ships is still the subject of much difference of opinion among men of science. Thus, it is admitted that fluid friction is independent of the pressure of the fluid upon the body moving through it, that it is directly as the wetted surface, and that it varies nearly as the square of the velocity. The friction of a body moving through a fluid is believed to be irrespective of the nature of the surface of the body, whether smooth or rough, a couche or stratum of liquid particles being carried along by the inequalities of a rough surface, the real fluid friction being, therefore, between separate and successive laminæ of fluid particles, rather than between the body itself and the fluid. We know, however, that a vessel, the bottom of which is covered by barnacles, and especially by long weeds, is greatly retarded in its passage through the water, but this fact is not absolutely irreconcileable with that of the uniformity of fluid friction upon all surfaces at the same speed. For, in the first place, shells, weeds, &c., actually enlarge a ship, giving it greater midship section, and greater extent of resisting surface. A great increase of resistance is occasioned also by the flowing of water between separate weeds and shells, and so, too, if a shell project, say, 3 in., and occasion head resistance due to such projection, and if a short distance aft of this another shell project to the same extent, and so on in a series, successive head resistances may be thus encountered equal perhaps to what would be due to a very large increase of the absolute midship section. Colonel Beaufoy, whose experiments, made about sixty years ago, on the resistance to floating bodies, were among the most complete of their kind ever made, concluded, however, that the friction of a smoothly painted board was one-eighth greater, after it had been well soaked in water, than when it was quite dry. With 50 square feet of smoothly painted board, which had lain for a long time in water, he found the friction to be 7¼ lb., at 4 knots an hour, and 25·04 lb. at 8 knots, a ratio rather less than that of the square of the speed. His estimate for a speed of 13 knots an hour was 1·2 lb. per square foot of the wetted surface of a vessel's bottom. He concluded that the friction on the sides of floating bodies was less at a few feet below the surface than at the surface. The friction of water flowing within pipes is now known to be twice that upon the same extent of surface of a body floating in open water, and a very large part of the power of a marine engine is absorbed in forcing a boat through a narrow channel say of but twice the width of the boat itself.

On a recent occasion this question of skin resistance was discussed by several of the first authorities in such matters. Mr. Scott Russell maintained that, at 26 statute miles an hour, the skin resistance would be 8 lb. per square foot of wetted surface, Mr. Hawksley believed it to be 1 9-16ths lb. per square foot at 10 miles an hour, or 15 ft. per second, and that, at high speeds, the resistance due to midship section virtually disappeared, while Mr. Phipps considered the skin resistance amounted to about 1 lb. per square foot at a speed of 12·2 miles per hour, or 17·9 ft. per second, which was not far from Colonel Beaufoy's conclusion. Mr. Russell's estimate, for a speed of 12 miles an hour, was 2 lb. per square foot.

It is certainly extraordinary when engineers of reputation speak of extinguishing the resistance due to midship section. The Holyhead boats, with 336 square feet of immersed midship section, force aside 17,000 tons of water per minute when running at 20 statute miles an hour, the water being forced at least 16 ft. aside on the average. The mere pressure of the water against the sides of the hull, however great it may be, does not, upon the first law of fluid friction, at all affect the result. So far as the mere inertia of the water is concerned, the boat acts like a wedge in overcoming it, and the effort is altogether independent of mere fluid friction. Who can suppose that if the 13,000 square feet of immersed surface of the Holyhead boats were represented by a thin vertical plate 650ft. long, and immersed 10ft., giving the same wetted surface, 4,750 indicated horse power would be required to drive it through the water at the rate of 20¼ statute miles an hour; this having been the actual power expended in driving the "Leinster" at that speed? This would give a skin resistance of about 6¾ lb. per square foot, a rate very nearly twice that which has been obtained by actual experiments at moderate velocities, the known rate of increase with velocity being not greater, at most, than as the square of the velocity.

Mr. Russell observed, during the discussion, that he did not believe that a speed of 20 miles an hour could be obtained with any boat less than 300 ft. long. Mr. Russell considers that any boat, intended to go at that speed, must have an entrance 168 ft. long, because that is the length of the wave of the first order moving at 20 miles an hour. This length of entrance is prescribed altogether irrespective of the width of the boat. An entrance of 168 ft. requires a run of 120 ft., so that, even without any length of straight middle body, 288 ft. would be required to make 20 miles an hour, no matter what the draught, the displacement, or the power! Yet, only the other day, the "Esploratore," an Italian *aviso*, with a copper-bottomed hull, built by Wigram, and with engines by Penn, attained a speed of 19·86 statute miles on trial, although the length between perpendiculars was but 240 ft. And although Mr. Russell, for some reason which we cannot understand, believes the skin resistance of an iron ship to be greater than that of a copper bottom (the former being supposed clean) it turned out that the whole resistance of the "Esploratore" was nearly 5¼ lb. for every square foot of immersed surface, say 8,400 square feet or thereabouts. On the Clyde, speeds of 20 miles an hour are made by boats only 200 ft. long; and Mr. Russell once, at the Royal Institution, admitted his belief that the American boats attained speeds of at least 22 miles an hour, although he made no reservation as to length. The "Daniel Drew," on which the Prince of Wales ascended the Hudson from West Point to Albany, has made 25 miles an hour against a slight current, and yet she is but about 250 ft. long. So much for the necessity of lengths of 300ft. for speeds of 20 miles an hour. Even if the whole resistance to the motion of a vessel were that arising from its adhesion to the water, and if the forcing aside of many thousand tons of water per minute, to a distance of 16ft. to 20ft. were to count for nothing, it is still evident that, if the friction of the skin were 6¾ lb. per square foot at 20 miles an hour, 2,400-horse power would drive 6,500 square ft. of surface through the water at that speed with the same ease as twice that power would carry twice the surface, and in the former case the whole surface might be in a boat only 150ft. long.

The notion that the whole resistance to the motion of a steam-vessel consists in fluid friction is, of course, in opposition to any presumption of advantage in the case of relatively long ships. If a ship 300 ft. long present 500 square feet of immersed surface, and have a displacement of 2,500 tons, then an increase of 100 ft. in her length amidships would not increase her midship section: it would increase her immersed surface by but about 6,500 square feet, and it would increase her displacement by 1,430 tons. It is evident that, in proportion to what a vessel so lengthened can carry, she will have much less resistance than before, and although the question of strength is one of great gravity and consequence in connection with long ships, it is not unlikely that, if it were satisfactorily disposed of, many steamship lines now supported by Government bounty might, by doubling the length of their ships, soon become self-supporting.

If the resistance to steamships consists only of skin resistance, they should be made circular or hemispherical, so as to present the least surface in proportion to their displacement. The punch-bowl pattern would be that having the least "skin resistance," and in that form our ships would be veritable "tubs." Colonel Beaufoy made an experiment *a propos* to this question of resistance. He provided a sphere and a cylinder, both of the same diameter, the latter having hemispherical ends. The midship section was the same in each case, the cylinder having the greater displacement and immersed surface. Yet at a given speed the sphere required 64·87 lb. to move it, while the cylinder required but 46·29 lb.

Mr. Russell has mentioned a phenomenon which, he confesses, is apparently inexplicable. On looking along a vessel when she is going fast, a ribbon of water will be seen sticking to her which is in a condition altogether different from that further from the ship. This ribbon, Mr. Russell alleges, does not alter its breadth with any change in the speed of the boat; it is, he says, exactly 3 in. wide for a boat 100 ft. long; 6 in. wide for a boat of 200 ft.; and 9 in. for a vessel of 300 ft. in length. It is, Mr. Russell thinks, in tearing this ribbon into shreds that the whole power of the engines of a steam-vessel is expended at high speeds. No doubt power is thus absorbed; but not one-half, we believe, of all that is required in driving the vessel.—*The Engineer.*

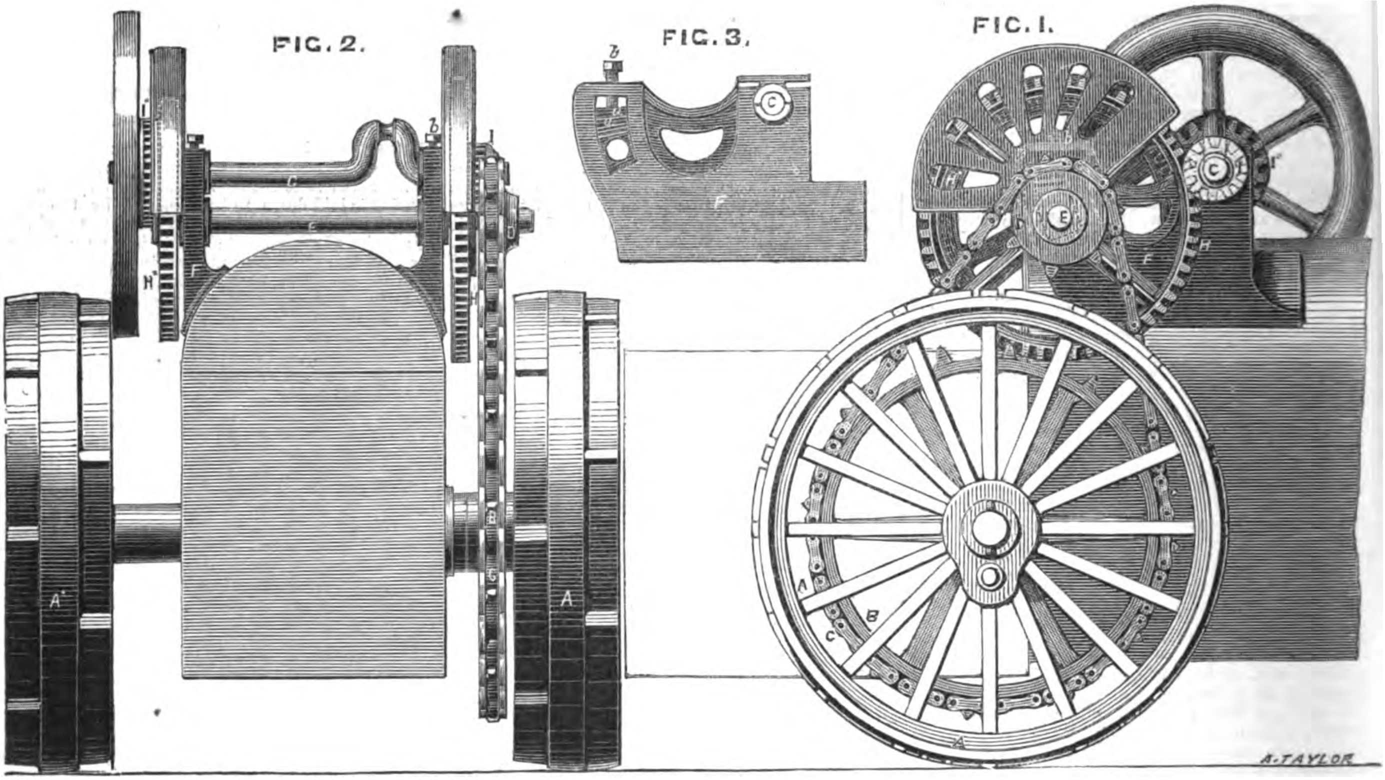
ECONOMICAL ADVANTAGES OF SYSTEM.

Persons who have noticed how work is carried on in many of our large machine-shops, cannot but wonder why it is that no established system and routine is laid down to be observed by the workmen. The advantages of such a plan are too obvious to require any comment; and it is, as we have remarked, incredible how many things are left to take care of themselves, that should have been regularly classified, and arranged with reference to the demands of the work. Let us take, for instance, the item of mandrils, as they are called here; or arbors, as they are better known in some other parts. These valuable, and indeed indispensable aids to machine work in too many instances have no more care or attention bestowed upon them than if they were scrap-iron. They are often made of iron, instead of steel, and are cut, hacked, battered, and ground in the centres, by careless workmen, until they are utterly useless. A good mandril costs too much money to be subjected to such usage, and this is but a little part of the evil; for where such bad practices prevail there are not likely to be good workmen, and no shop can create or maintain a reputation where such carelessness is permitted.

Such folly and wastefulness as this must and should receive the severest condemnation of every right-thinking person. System as applied to the use of mandrils, is not the only place where it might be adopted with good results. Let us take the matter of measurement, for instance. In too many workshops the only reliance for proper fitting work is placed on an old, illegible, greasy, shaky-jointed, smooth-ended, wooden two-foot rule; which is about as useful for measuring purposes as so many inches of a broomstick. With this valuable aid, the old-fogy workman gravely takes a pair of callipers, and turns up a shaft from it to the size of "four inches." Another individual bores out a wheel to "fit" it by *his* wooden rule; and the consequence is that, between them, about a sixteenth of an inch of daylight passes through the wheel when the shaft goes in, or else there is a similar quantity of iron to be forced through the bore of the wheel in excess of the proper measurement. These are not instances created for the sake of maintaining our assertion that some system is required, but are cases of too frequent occurrence, as every one familiar with the routine of a machine-shop can testify. What is true in the case of lathe-work is also correct as regards every other transaction where fitting depends upon actual measurement. The steel scale is an excellent substitute for the boxwood rule, and should be more generally employed by workmen; but none of these can compare in value with a set of standard gauges such as are used in the Novelty Iron Works in this city and other large and smaller machine works throughout the country. These guages, we believe, are made on the Whitworth standard, and for sizes of three inches are divided into sixteenths, while beyond that they are only graduated to eighths of an inch. These gauges can be made so that one end can be used in turning a shaft, while the other end is flattened like a fish-tail, and reduced to exactly the dimensions of the calliper ends. Thus a shaft turned by one end, and a hole bored so as to fit the opposite part, will cause both wheel and shaft to fit each other beautifully, without loss of time. This is so much better than the old-fashioned way of using callipers for the purpose, that the two are not to be spoken of in the same breath.

Every part of the machine business can be made the subject of a general and thorough reform. There are numbers of establishments in which wooden chucks, mandrils, bolts, washers, old files, stray hammers, lathe-tools, and every conceivable thing are scattered under the benches, lying on window-sills, and trodden under foot generally. What a spectacle of slovenliness and disorder such a place presents; and what a commentary it is upon the character of those in charge! The pecuniary loss sustained by such a state of things is enormous, and might be dispensed with by having everything in its proper place, and a regular and recognized system of procedure for all, so that work would not be spoiled by carelessness. One of the many advantages would also be soon apparent in encouraging a better class of workmen, and result in good to the whole trade generally.—*Scientific American.*

AVELING'S IMPROVEMENTS IN TRACTION ENGINES.



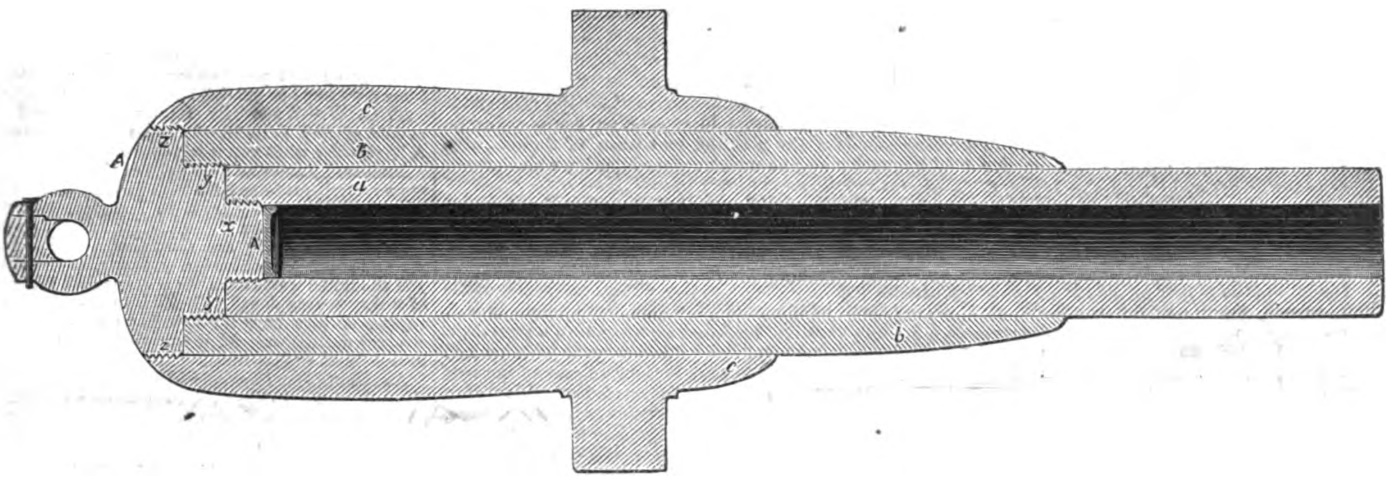
AVELING'S IMPROVEMENTS IN TRACTION ENGINES.

This invention relates to the application to traction engines of certain improvements in their details, with the view both of simplifying their construction and greatly enhancing their efficiency. It is well known that it is desirable to change the relative speeds of the carrying wheels and the crank shaft according to the varying levels or the character of the ground over which the engine is travelling. To effect this, many complex or cumbrous contrivances have been adopted which not only increased the weight but the cost of the engine. It is proposed to attain this end by the novel means shown in the accompanying drawing, in which fig. 1 is a side elevation, and fig. 2 an end view of so much of a traction engine as will serve to explain the nature of these improvements, the motion of the crank shaft being transmitted through an endless chain to the driven wheel. The carrying wheels A, A*, are made broad and cast with an annular rib in the middle of the periphery for running on hard ground and with lateral projections for ensuring a firm bite of the ground. On the boss of the wheel A, is keyed the ordinary chain wheel B, round which the chain C passes from a chain pinion D. This chain pinion is keyed on to a transverse shaft E, which is carried by brackets F that serve also to carry the crank shaft G. By thus mountiing these two shafts E and G on the same brackets, the use of additional fastenings for securing the brackets to the boiler are avoided, while at the same time, by the peculiar arrangement of the shafts, the distance between the chain pinion D and the crank shaft G is increased sufficiently to permit of the use of a larger diameter of pinion than usual, which is a matter of considerable importance as respects the maintenance of the gearing in efficient working order. Keyed to the opposite ends of the counter shaft E are spur wheels H, H*, having different numbers of teeth to suit two different speeds of driving, and into these wheels gear spur pinions I, I*, of varying diameter on the crank shaft. These pinions are free to slide on feathers on their shaft in order that either may be thrown into action at pleasure according to the driving speed required. They are by preference shifted by hand and kept in or out of gear as the case may be by the application of elastic clips composed of a strip of thin steel lined with leather. The clips are made to clasp the shaft and retain their position thereon. But when the pinions require to be shifted the clips are first taken off the shaft and the pinions being shifted laterally by hand the clips are again applied, but so as to bear against either side of the boss of the pinions. They will thus act like a fixed collar on the shaft, maintaining the pinions in the required lateral position. To allow of the slack of the chain C being taken up, the counter shaft bearings are set in segment slots in the brackets F, as shown best in the detached view, fig. 3. The segment slot, it will be seen is struck from the axis of the crank shaft G. The bearings of the counter shaft may be raised to any required height (within the limits of the slotted brackets) suitable for bringing the chain to tension by the insertion of blocks *a*, *a*, below the bearings, and they are then to be held firmly by a binding screw *b*. From this explanation it will be understood that when it is desired to reduce the speed transmitted to the driven wheel in order that the engine may be enabled to ascend an incline, it will only be necessary to throw the small pinion I into gear with its spur wheel H*. It will also be seen that when the greatest stress is put on the gearing, the strain will be directly through the gearing, and thus the counter shaft E will not suffer from torsion. When, however, the work is less severe the motion will be transmitted through the pinion and wheel I*, H*, and thence through the shaft E to the chain pinion D. In order to provide for a still further variation of speed it is only necessary to change the pinion D for one of less or more teeth, and two additional speeds will be thereby obtained.

IMPROVEMENTS IN LIGHTING HALLS, THEATRES, &c.

Mr. Enoch Bassett Keeling, architect, of Gray's Inn, has recently patented an improvement in lighting halls, theatres, &c. The invention is intended to be applied to the lighting of halls, theatres, and other buildings, and relates to the diffusion of intense light, and to the prevention of shadows. The inventor takes an electric light, a lime light, or other source of intense light, and places it in some elevated spot above the space to be lighted. Under or before, or part under and part before, this light he suspends or fits a plain white, tinted, or coloured curtain or screen, and again, in some instances, he places under or before a ceiling of glass or other transparent medium. By these means he removes the obstacles that have hitherto prevented the successful application of the electric, lime, or other intense lights to the lighting of the interiors of large rooms and public edifices, and that also have all but confined these sources of light to the position of mere scientific curiosities. It is well known that the chief obstacles have been the intense brilliancy of the lights, their unpleasant white or ghastly hue, and the dense black shadows thrown by them. The first, however, gives us so far a margin, that the medium of the curtain absolutely utilizes the objection by the sacrifice of brilliancy, but by the complete diffusion of the rays. The second obstacle is overcome by the tint or colour of the curtain or screen giving any hue most desirable to assimilate with any of the lights now usually employed, whether it be that of gas, of any description of oil lamp, of that of any wax or other candles. The relative use of the curtain or screen to the source of light is the same as that of the clouds to the sun. On a day of bright sunshine the radiating action of a centralized source of light casts shadows of a depth and darkness proportionate to the brilliancy and intensity of the light, whereas on a day without direct sunshine —that is, with a clouded sky—there is a pervading, an even, and a diffused light, and an almost total absence of shadow. The clouds in this instance cause a diffusion of the direct rays of the sun, which, in our case, is met by the employment of the curtain, blind, or screen combining imperviousness of glare with softness of light. The following are among some of the advantages derived from the employment of this invention in its application to public and private buildings: —Great excellence in the diffusion and softness of light, economy in cost, absence of all damage or detriment to the decorations of the apartment, and prevention of the risk of fire, as would be consequent upon the use of ordinary gas; and the power of assimilating the hue of light in the illu-

WHITWORTH AND HULSE'S IMPROVEMENTS IN ORDNANCE.



mination of the main body of a building with those used in remote portions, or in communicating apartments, that no difference would be perceptible, and the power of supplementing this light by the employment of gas in remote positions.

To illustrate the carrying of the invention into effect, we will suppose that it is required to light a hall. In a chamber constructed immediately above the ceiling are placed one or more lime lights, the number being proportional to the extent and cubical contents of the apartment and the proportion of light required, and at a distance below, only to be regulated by circumstances, are suspended across the chamber, by rings, or cords, or in any other most suitable manner, a curtain or screen, by preference of oiled silk, of a colour or tint to give the most desirable hue to the light. Mr. Keeling finds that the most pleasing light is produced by an oil silk curtain or screen of a light pink tint. The screen may either hang loosely or be drawn tightly across. The ceiling of the hall below the chamber he constructs in the ordinary manner of a ceiling, light, and of figured or ground glass. The intense rays of the light are, as before shown, diffused in passing through the curtain or screen, and the hall is pleasantly and effectually illuminated, and devoid of deep shadows. In some cases, for large halls and other apartments, it may be better to have two or more chambers above the ceiling, each with its own light or lights and curtains or screens arranged as before stated. The results attained would be a more shadowless and equal distribution of the light in the apartment below. Where the character or construction of the building would not allow of a chamber being constructed above the ceiling, the same end would be obtained by constructing the chamber below the ceiling in the form of an inverted dome in the centre or at one or both ends, or as, by preference, at each angle of the apartment; in the former case the curtain or screen would be under and around the light, as also would the glass screen, and in the latter cases under and before the light. The glass screens may, in certain instances, be entirely omitted.

WHITWORTH AND HULSE'S IMPROVEMENTS IN ORDNANCE.

The following improvements in guns have just been patented by Messrs. Joseph Whitworth and William Hulse, engineers, Manchester:—

This invention consists in the employment of an improved method of manufacturing ordnance made of what is now termed homogeneous metal, or mild steel, or steel iron, or other similar material.

The patentees cast an ingot with a hole through it, and afterwards hammer it between an angular-shaped anvil block and a hammer head of a similar or a flat shape. A mandril of a taper form is inserted through the hole cast in the ingot, and the operation of hammering or forging proceeds till the mandril becomes too hot, from its contact with the heated metal of the ingot; it is then withdrawn, and a cold mandril is inserted in the place of the heated one, and the hammer or forging is continued until it is made of the desired size and shape. If preferred, a hollow mandril may be used and cooled internally. The hammered tubular ingot is subsequently annealed. If necessary, the interior surface of the tubular ingot may be "converted" to the required depth.

For heavy guns, for ships and fortifications, constructed on what is termed the "built-up" system, the inventors make the inner tube from a tubular ingot, and strengthen the inner tube with cylinders made of homogeneous metal, as above described, and put on, by hydraulic pressure or other suitable means, in one or more series, as required. For closing the breech of these built-up guns, a breech is employed on which screws of two or more different diameters are cut. The screw with the smallest diameter takes into an interior screw in the breech end of the inner tube, and the screws of the larger diameters take at the same time into interior screws made in the second, or second and other series of hoops.

In the case of guns which do not require to be hooped the barrel is made from an ingot cast with a hole through, as above described, and bored and rifled after it has been forged and annealed.

In making the trunnions of ordnance, the patentees cast them with a hole through, employing homogeneous metal or strong pig iron or other suitable metal; the hole is afterwards bored, and for a portion of its length, or for its entire length, is screwed, the barrel or hoop of the gun (as the case may be) being screwed to receive it; or the trunnions may be made with, and form part of the outer hoop, as shown in the drawing.

The accompanying drawing represents the gun and the mode of constructing and attaching the breech by means of a triple screw; a screw with two different diameters is applied in the same way.

a, *a*, is the inner tube of a built-up gun with a first and second series of hoops *b*, *b*, and *c*, *c*; A, A, is the screw for closing the breech, having three series of different diameters, the smallest of which, *x*, takes into the screwed end of the inner tube *a*; the medium-sized screw *y* takes into the screwed end of the hoops *b*, *b*; and the largest size screw *z*, *z*, into the screwed end of the third series of hoops. By this arrangement the free and sudden expansion of the gun laterally by the action of the explosion is allowed, whilst the inner tube with its strengthening hoops are each made to take their own proper share of the end pressure arising from the explosion.

BAMFORD, BLOMLEY, TAYLOR, AND LETT'S IMPROVEMENTS IN LOOMS FOR WEAVING.

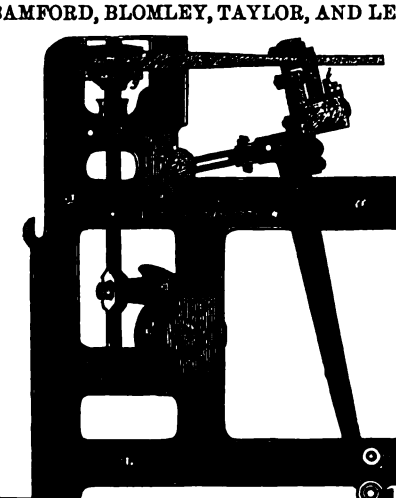


FIG. 1.

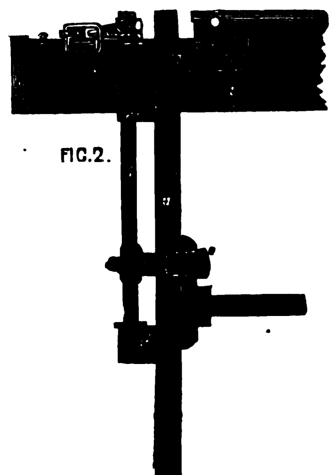

FIG. 2.

BAMFORD, BLOMLEY, TAYLOR, AND LETT'S IMPROVEMENTS IN LOOMS FOR WEAVING.

The following improvements in looms have been recently patented by Messrs. Abraham Bamford, Richard Blomley, R. Taylor, and J. Lett, all of Rochdale, Lancashire. The invention is described as follows:—

Hitherto in looms for weaving, it has been customary to connect the picking stick, when it has not moved with the lathe, to the picker by means of a strap, band, or chain.

Now the nature of this invention consists in connecting the picker to the picking stick without the intervention of the strap, band, or chain.

Fig. 1, in the accompanying drawing, repre-

sents an end elevation of a loom such as is used to weave calico, with this invention applied; and fig. 2 represents a front elevation of one end of the same.

a is the frame side of the loom; b, the driving or crank shaft; c, the tappet shaft, on which is mounted the tappet d, which works against the bowl e, and causes it to vibrate to and fro; this bowl is mounted on a stud e^1, which is screwed fast to the upright shaft, which is supported by the brackets f_1 and f^2; on the top of the shaft f is fastened a plate g, to which is fastened the picking stick; h is a spiral spring, which keeps the bowl e against the tappet d; i is the lathe; k, the shuttle-box bottom, which has a slot in it for the end of the picker to slide in; l is the shuttle-box front; m, the shuttle-box back, and n the spindle on which the picker slides; o, in fig. 2, is the shuttle-box end, it supports one end of the shuttle-box back, and one end of the spindle n: it is not shown in fig. 1, so that the picker and picking stick might be more distinctly seen. All the parts above enumerated are, as usually constructed, with the exception of the upright shaft which is made rather shorter, so as to bring the picking stick lower down; and the brackets f_1 and f_2, which are made rather longer, so as to throw the upright shaft rather farther from the loom side. p is the picker, which is made with a slot in the upper part of it, as shown in fig. 2, for the end of the picking stick to come through, so that when the picking stick moves, it pushes the picker backwards or forwards along the spindle n; by this means the straps, bands, or chains usually employed to connect the picking stick to the picker are dispensed with.

THE EFFECTS OF CONGELATION UPON WATER.

Dr. Robinet, a member of the Academy of Medicine, Paris, has published an account of experiments conducted by him to test the effects of congelation upon drinking-water. It is well known that the ice which is formed in the sea yields nothing but fresh water, all the salt having been eliminated by congelation. In the northern parts of Europe this property is turned to account for the extraction of salt from sea water; for a large sheet of the latter having been left to freeze, the ice is afterwards cut away, and the unfrozen water left below is so rich in salt as to require very little evaporation to yield it in a solid state. This property will also serve to analyze wine. Suppose it was required to determine the quantity of water fraudulently added to a certain wine; by exposing it to the action of artificial refrigeration, all the water would be alone, and the wine left in its purity. By a similar process, ships at sea, being short of water, might be supplied with this necessary article. We will suppose the temperature of sea water under the tropics to be 30 deg. centigrade. If a quantity be exposed in a vessel to the action of a mixture of sulphate of soda and hydrochloric acid, two very cheap commodities, the temperature of the water will fall to 10 deg. below freezing point. Let it then be exposed to a second mixture of the same kind, generally eight parts of sulphate to five of the acid, and the temperature may be lowered to 17 deg. below freezing point. Congealed water is then obtained free from salt, and may be used with impunity. Dr. Robinet has added a new fact to this theory by showing that the water of springs and rivers loses all its salts by congelation. These salts are chiefly those of lime and magnesia. The water subjected to experiment was that of the lakes of the Bois de Boulogne, the ice of which was found to be entirely free from the above-mentioned salts. Such, indeed, is the chemical purity of the water thus obtained, that it may in most instances be substituted for distilled water.

The first iron ship built in Liverpool by shipwrights, was launched on Wednesday from the ship yard of Messrs Potter and Co. She has been named the "Bedfordshire."

Legal Intelligence.

The following case was tried on Monday, at Gloucester, before Mr. Baron Bramwell and a special jury :—

BADHAM *v.* BALLARD AND BEASSEY.

This was an action brought for the negligence of the defendants in setting on fire some cattle sheds of the plaintiff, by reason of their using a steam-engine which emitted sparks, which caused the injury.

The plaintiff was the occupier of a farm at Beckford, near the Ashchurch and Evesham Railway, which the defendants were constructing, as contractors. On the 19th of May, at about 4 o'clock in the afternoon, some cattle sheds of the plaintiff, which were near a branch line used by the defendants to run to a gravel-pit and bring away ballast, were seen to be on fire. The fire was observed in four places on the roof of these sheds, which formed two sides of a square—one running alongside of the line of rails, and the other at right angles to them. The fire was on the outside and near the top of the roof of the shed which run parallel to the rails. The funnel of the defendants' engine, as it ran out of the ballast-pit, passed about 10 or 11 yards from the sheds, and the branch line being at this place, in a cutting, the top of the funnel would be some eight or ten feet below the roof of the sheds. A strong wind was blowing that afternoon in a direction across the rails and towards the sheds. An engine called the "Malvern" had left the ballast-pit with a load of trucks, and had passed by the sheds, according to plaintiff's witnesses, only five minutes before the fire was observed. Before the day in question sparks had been seen coming from the funnel of the "Malvern." The sheds were thatched, and were built of furze and gorse, and in a very short time were wholly consumed. The contents have been valued between the plaintiff and an insurance office at £340, and the plaintiff having been paid that sum, was suing as trustee for the office. For the defence, it was proved that tramps had been seen in the sheds in question, that persons had been seen smoking there, that workmen going to the ballast-pit were in the habit of passing along the top of the cutting between the sheds and the rail, that rye and stubble had been burnt on the plaintiff's farm about the time of the fire, and that other fires had occurred in the neighbourhood about that date. The "Malvern," on the day in question, was burning coal, and it was suggested on behalf of the plaintiff by a number of scientific witnesses that the escape of sparks from the funnel might have been prevented by the use of wire caps over the top of the funnel, or of "Venetian blinds" over the fire-holes, or of a brick arch over the fire-box. It was proved that the London and South-Western line had recently resumed the use of caps, which had been common ten years ago, and had fitted them to the majority of their engines. It was also proved that although the use of coal instead of coke had been recently resumed by railway companies, yet, inasmuch as coal was more likely to throw sparks than coke, some additional precaution became necessary. For the defendants, scientific evidence was also called, and it was proved that the "Malvern" was a very good engine, well constructed in all parts. Several engineers expressed an opinion that caps were useless, that good coal was not likely to throw more sparks than coke, and that, under all the circumstances of this line, and of the kind of work the "Malvern" was doing, it was highly improbable, not to say impossible, that any sparks could have been thrown from the funnel. It was also suggested that the "Malvern" was priming on this day, and that any sparks must therefore have been extinguished before they could escape. The advantage of caps was denied, as also of the other precautions suggested by the plantiff, and the defendants' witnesses were not aware that the use of such expedients had been lately resumed by the South-Western Railway.

The learned Judge left the question of negligence to the jury, who, on that point, found a verdict for the plaintiff.

TO CORRESPONDENTS.

Received.—T. D.—E. B.—G. F.—J. B. and Co. —C. Y.—E. F. and Co.

Spectrum.—The experiments you refer to have so far been very successful, but they have scarcely gone far enough yet to warrant full confidence in them; we hope to publish them at a future date.

T. C. W.—We really cannot recommend the maker of any particular species of machinery. Advertise for what you want.

Messrs. Dalton and Co.—Few, if any iron passenger carriages have been built in England. They have been frequently tried in America, but with very doubtful success.

Locomotive.—We are somewhat surprised by your question. If you are an engineer, as you state, you should be well aware that very many varieties of spring are employed. Besides india-rubber and volute, springs have been made in the form of a straight flat bar tapered at each end. The "Manhattan" had such springs.

An Engineer (Leeds).—We believe the largest steam-hammer in the world, is that at Creusot, in France. The wrought-iron head weighs nearly 12 tons; the fall 10ft.; and the weight of the anvil block, cast where it is, 86 tons.

T. M. M. (Whitechurch).—1. Yes. 2. Compressed cotton as a backing for armour-plates has been proposed long since.

PETROLEUM GAS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—For the information of your readers and the public generally, and for my own satisfaction, and to testify to the able report of Mr. Bower, as published in your Magazine of the 16th August, I beg to state that the double-acting gas apparatus mentioned in that report—and capable of making, with equal facility, either coal gas, petroleum gas, oil gas, or wood gas—may be seen and tested at the General Gas Apparatus Depot, 218, Great Portland-street, W., where I attend daily from 10 to 3. The retort (which I invented and named the "Fitzmaurice retort," and which gives the great success) was illustrated and fully described in the Mechanics' Magazine in March, 1863. The good action and durability of the said retorts have been extraordinary—almost more than expected—as some fixed by me at the gasworks at Nutfield, Farningham, Linfield, the Earl of Shrewsbury's, Lord Hill's, and other places, upwards of three years ago, and now in action, testify, and from the engineers of which places I have the most encouraging and unsolicited reports.

I may add that my experience teaches me that "petroleum gas," or even the rosin-oil gas, or good cannel coal gas, may be depended on for lighting railway or other carriages with portable gas. The "Albert" vase for portable gas (invented and made by me, and now in possession of, and worked by Mr. Bower) is of copper bronzed, and in the shape of a pear inverted, fitted with ornamental handles, foot, high-pressure stop cock, pillar, and gas-burner, all moveable for table use. The processes are all described in a pamphlet called "Cottage Gasworks," published by Hebert, Cheapside.

I am, &c.,

James Copcutt.

Aylesbury and London,
Aug. 18, 1863.

Miscellanea.

The honour of knighthood is to be conferred on Mr. Goldsworthy Gurney, the inventor of a common road steam carriage, the Bude light, and also the successful ventilator of the two Houses of Parliament.

Messrs. A. Stephens and Son, have just launched from their new shipbuilding shed, at Kelvinhaugh, another of their wood and iron combination ships. The vessel is in question is a fine screw steamer of about 1,200 tons, is named the "Sea King," owned in London, and is, we understand, the first screw steamship built on the principle of iron frames and wood planking. She has been specially constructed for the China trade.

The Millwall Ironworks and Shipbuilding Company have received an order from the Admiralty to

construct within one month a target on the design of Mr. Reed, the recently-appointed Chief Constructor of the Navy. The price decided upon is £1,576, and the object sought by the Department of the Controller of the Navy is to test a principle by which it is proposed to secure in a reliable manner iron plates to the sides of the ships composing our iron-clad navy.

The Metropolitan Board of Works have accepted the offer of the Governors of St. Thomas's Hospital to purchase for £95,000 the ground on the southern embankment opposite the Houses of Parliament, as a site for the new hospital. The extent of the ground is 8½ acres.

Sunday, the 9th inst., was the hottest day, not only of the present year, but of this century, at Paris.

A public company is being formed for the embankment and reclamation of the Goodwin Sands into a valuable island, whereupon to build a new township, fortifications, docks, life-boat station, and wharfs; also to reclaim the land for agricultural purposes. By the proposed embankment, the whole of the channel between the Goodwin and the Break would become entirely clear. The sunken ships and treasures, it is thought, would pay all expenses. The land to be reclaimed will consist of about 20,000 acres.

A fresh application of electricity has just been made in an apparatus for voting presented to the Parliament of Vienna. Each of the deputies has before him, at his seat in the chamber, two knobs, one white and the other black, and the vote is given by pressing one of them. Two frames are placed by the side of the president, upon one of which the affirmative votes appear as white points on a black ground, and the negative upon the other, in black spots on a white ground. Each pressure of the deputy's hand on the knobs is marked by electricity upon one of the tablets, according to the vote which he wishes to give.

The annual report of the Royal Insurance Company, just issued, states that the fire premiums exceeded £300,000 in the last twelve months. The life premiums for 1862 show an advance of the preceding year of £18,952. From the report it appears, moreover, that the success of 1862 is likely to be even exceeded by that of the present year, as indicated by the seven months already elapsed.

We learn from the *Typographical Advertiser* that a gentleman, a large capitalist, and one of the most successful inventors of the day, has succeeded in chemically treating the pulp, during the process of manufacturing printing paper, in such a manner that when the paper is impressed upon the uninked types the chemical particles are crushed, and a perfect black impression is the result. The advantage sought to be obtained is the discarding of ink and rollers; and, by revolutionizing printing machinery, and printing from a continuous roll af paper, it is calculated that time occupied in impressing large quantities of paper will be nominal in comparison to the requirements of the present day. Cleanliness in the printing office would thus become proverbial, and the time now wasted in making and distributing the rollers obviated.

The following figures show the result of the Examinations of Science Schools and Classes of the Science and Art Department of the Committee of Council on Education:—The total number of individuals under instruction in 1863 was 3,811; and in 1862, 3,413. Of these 869 were in uncertificated classes last year, and about 700 this, making the increase in students in certificated classes between May, 1862, and May, 1863, 566. The total number of individual candidates who applied for examination in 1863 was 2,000; and in 1862, 1,708. The number of Papers worked in 1863 was 2,671, there being in practical, plain, and descriptive geometry, 288; in mechanical and machine drawing, 194; in building, construction, and naval architecture, 107; in theoretical mechanics, 35; in applied mechanics, 22; in acoustics, light, and heat, 121; in magnetism and electricity, 207: in inorganic chemistry, 679; in organic chemistry, 157; in geology, 129; in mineralogy, 46; in animal physiology, 343; in zoology, 41; in vegetable physiology and economic botany, 126; in systematic botany, 84; in mining, 29; in metallurgy, 63. In 1862 the total number of Papers was 1,943. The number of provincial local centres where examinations were held in 1863 was 64; and in 1862, 45. The number of metropolitan centres where examinations were held (including this Department) was, in 1863, 7; in 1862, 9. In 1863 the total number of successes were 2,127—viz., passes, 668; honourable mentions, 510; third grade prizes, 458; second grade prizes, 309; and first grade prizes, 182; and 544 failures. In 1862 the total number of successes was 1,480—viz., passes, 791; third grade prizes, 296; second grade prizes, 237; and first grade prizes, 156; and 463 failures.

The Constitutional Life Assurance and Loan Company appears to be in a prosperous condition. The total number of proposals including life, sickness and death, during the last year, was 4,333, assuring £56,975, and producing annually £3,603.

An unprecedented spectacle was witnessed by a large concourse of people on the Tyne on Saturday afternoon—viz., the launching of four large iron steamships at the same instant of time at a signal from a gun. The launches were from the building yards of Messrs. Palmer Brothers, at Jarrow and Howdon, which are nearly opposite each other; and the scene of four noble vessels rushing into the river at the same moment was such as has probably never been witnessed upon a commercial river before, and will be long remembered by the large crowd who witnessed it. The vessels were the "Latona," being the sixth of a line of steamships built by Messrs. Palmer for a company trading between London and Italy; the "John M'Intyre," a large screw collier, the property of Messrs. Cory and Co., of the Coal Exchange, London; the "No. 1," built for a Rotterdam firm, and, it is stated, intended to trade with Japan; and the "Europa," intended to be employed in the passenger and goods trade between Genoa and the Island of Sardinia. Their aggregate tonnage is about 4,300. To give some idea of the enormous development of the iron shipbuilding trade in the Tyne, it will suffice to state that this firm alone has 16,000 tons of iron shipping on the stocks, besides orders on hand nearly reaching 40,000 tons.

The iron-clad battery "Onondaga," says the *Scientific American*, was launched from the Continental Works, at Greenpoint, L. I., at half-past eight o'clock on the morning of the 29th ult. The "Onondaga" is known in naval circles as the "Quintard battery," so called from the gentleman who contracted for her, Mr. George W. Quintard, proprietor of the Morgan Iron Works. She is 230 ft. long, 52 ft. wide, and will have two turrets on the "Monitor" pattern, with the exception that a part of the turret is composed of heavy plates, instead of consecutive layers of thin ones, as in all the other "Monitors." The "Onondaga" is also peculiar in her side armour, which consists of heavy single plates 4½ in. thick, faced with timber 13 in. thick, which is in turn covered with an iron plate 1 in. thick. The deck is laid with plating amounting to 2 in. in thickness; and the rest of the vessel is very similar in general arrangement to others of the same class. The propelling power is two pair of horizontal back-acting engines, each driving a screw under the quarter. The "Onondaga" has no overhang forward and but little aft, and it is thought will prove a good sea-boat. The vessel was launched very successfully, going down the ways with great rapidity, and running far out into the river. The turrets are not yet placed on board, but are ready for erection. The rest of the machinery is all on board.

Cotton has been found in Cuba growing on a vine, which runs along and covers the ground. It is not very fine, but white and strong. As in the very hottest seasons there are heavy dews in Jamaica, it has been supposed that this kind of cotton is likely to succeed on the lands on which the tree and Sea Island cottons will not thrive. A very small quantity was tried in various parts of Jamaica, and some at the reformatory near Kingston. Through the kind attention of Earl Russell and the Foreign Office, the Jamaica Cotton Company are likely to obtain a considerable quantity of the seed.

A firm in Bridgewater, Massachusetts, are making a gun from wrought iron, which will weigh, when completed, about 17 tons. It is forged solid, in an octagonal form, with the cavity bored out 13 in. in diameter, and will be hooped with strong bands of iron put on by hydraulic pressure. The lathe on which the metal is being turned is one of the largest in the world.

The launch of the "Research," 4, 1,250 tons, iron-cased frigate, the first of the vessels constructed on Mr. Reed's plan, took place at Pembroke on Saturday evening. The ceremony of "christening" the ship was performed by Miss Kerr, daughter of Captain Lord F. H. Kerr, of the "Blenheim," 60, 400-horse-power, flag-ship at Pembroke. The vessel's mean draught of water after launching was found to be only 8 ft., or nearly a foot less than was calculated upon by the dockyard authorities. As she lay on the stocks there was but one opinion as to her ugliness, but, on getting afloat she was pronounced a rather stylish craft. She is intended to carry only four heavy guns, but will be entirely encased with from 4 to 4½-inch armour-plates. At present she has only four plates bolted to her sides, but the remainder are to be put on as speedily as possible, after which the "Research" will be sent to Devonport to be fitted for commission.

The new iron frigate "Bellerophon," is to be exactly 300 ft. in length, with a breadth of beam of 57 ft.; her draught of water will not, it is expected, exceed 26 ft. Orders have been received at the Chatham Dockyard for the construction of a target to be used in a series of experiments at Shoeburyness, to test the strength of the manner in which it is proposed to construct her sides. This target is now being put together at the Millwall Ironworks, and will shortly be ready to be operated upon. The target is to be constructed of 10-inch iron frames, placed about 2 ft. apart, on which will be first laid a covering of iron plates of about 2 in. in thickness. This will serve as the "skin" of the target, preparatory to a backing of 12-inch teak planking. The target will then be finally covered with iron armour-plates, of from 5 in. to 7 in. in thickness, but the exact thickness has not yet been decided upon. It is confidently expected that this construction will exceed in shot-resisting strength every other description of plating hitherto adopted in this country, and if the arrangement is found to succeed, the same mode of construction will be followed in building the "Bellerophon." It is, perhaps, the heaviest target yet made.

The *Army and Navy Gazette*, under the heading "Federal Facts and Un-English Fancies," says:—It strikes us that there is an unusual mode adopted by most of our public writers and journalists in dealing with the course of events in the American civil war. The question most important to us here in England is of a very military and political, not of a philosophical and metaphysical character. Whether the Americans lose or recover their liberties—whether they destroy or preserve State rights—whether they respect or annihilate the constitution, is for them a vital problem; but it does not so much practically concern us in Great Britain at the present moment, however curious and interesting for historical students it may be to study the words and acts of the model republicans. Great Britain is much more intimately concerned in the hard facts of the terrible war than in speculations as to greenbacks, habeas corpus, martial law, arbitrary arrests, taxation, and the like. She is most deeply interested in trying to discover whether the North is about to become a great military and naval power, with an overwhelming and triumphant army, and a fleet of great strength in their own waters. What use, then, is there in prophesying or speculating, in view of the facts before our eyes? These facts are, the retreat of Lee to the neighbourhood of Richmond, after a disastrous attempt on Pennsylvania, founded, it appears, on a miscalculation of the resoures of the Confederate Government in men, and the consequent reoccupation by the Federals of the Shenandoah Valley and Rappahannock; the complete possession of the Mississippi by the Federals, so that, contrary to our expectations, trade has commenced between St. Louis and New Orleans; their solid establishment in Tennessee and their less tranquil, but not less secure sway over Kentucky; their undisputed dominancy in the State of Mississippi itself; their approach to the frontiers of Georgia and Alabama; their grip of the seaboard tightening gradually; their strongholds established along the coast of North Carolina and South Carolina and Florida; their effectual severance of the States of Texas and Arkansas from the rest of the Confederacy; and their undisturbed hold of Missouri. Add to this catalogue the danger, very imminent to Charleston, Savannah, and Mobile, of destruction or capture by the Federal forces, and the increasing stringency of the Federal blockade—the vast losses of men not to be replaced on the part of the Confederacy, and the constant spread of Federal conquest; and it requires philosophy, metaphysics, historical parallels, and immense faith to believe that the South can continue her resistance to the North in the field, or preserve her States from the sway of Washington pro-consuls. On the other hand, there is said to be dissension in the North—there certainly have been riots in some Northern cities. The people will not enlist, and will not suffer conscription to be enforced. They will all be ruined by a financial crisis. The war is only carried on by "shoddy contractors"—very gallant must they be; and politicians, and clergy—very numerous and very valiant must they be, too. The country is so vast that it cannot be conquered or held. The North is not in earnest, or is tired of the war, or is corrupt, or, cowardly, and only fights with Irish and German hands which won't strike any longer—in fact, something is to take place which has certain

not yet taken place, and which is to undo the knot of facts accomplished which is just now pressing under the Southern ear. Let us continue—let us stick to our hard facts. In July, 1861, after the Battle of Bull Run, the boundary of the Southern Confederacy, as drawn by their bayonets in actual line, ran through the line of the Potomac, the centre of Kentucky, and the centre of Missouri. The Confederates held the Green River, had camps at Columbus, from which they threatened Cairo, and encamped higher up in Missouri, held St. Louis itself in alarm; they had possession of every seaport south of Baltimore; they had a blockade of the Potomac. Fort Pickens was the solitary standpost for the Federal flag in Southern seas. The line has now receded far indeed, and to it have marched up the advancing Federals. This has been accomplished, we are told, at the cost of an actual debt, on the 1st of July, 1863, of 1,097,274,356 dollars, or, in round numbers, of £219,600,000. Gold stands at 24 premium in New York; in Richmond it is 1,100 premium.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c.—*none.*
Boilers and Furnaces, 106, 125.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 137, 144.
Ships and Boats, including their fittings—*none.*
Cultivation of the Soil, including agricultural implements and machines, 120, 132.
Food and Beverages, including apparatus for preparing food for men and animals, 127, 135.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 107, 110, 112, 118, 121, 139, 143, 145.
Buildings and Building Materials, 124, 131.
Lighting, Heating, and Ventilating, 105, 113, 115, 129, 134, 146.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 101, 109, 111, 116, 140, 141, 142.
Metals, including apparatus for their manufacture, 114, 122, 123, 128, 130.
Chemistry and Photography, 102, 126, 133, 138.
Electrical Apparatus, 104.
Warfare, 136.
Letter-Press Printing, 117, 147.
Miscellaneous, 103, 108, 119.

101. J. B. Fenby. *A new or improved instrument or apparatus to be attached to pianofortes, organs, and other similar keyed musical instruments, for printing the score of any music performed on the said instruments.* Dated January 13, 1863.

This invention consists in certain mechanical arrangements actuated mainly by the agency of electricity, by the use of which the score of any music played upon the musical instrument to which the invention is attached is registered or printed. *Patent completed.*

102. T. Boyle. *An apparatus for multiplying indefinitely the reflections of all objects that are capable of being viewed in it, and to which the name of "The Comic Stereoscope" is given.* Dated January 13, 1863.

This invention consists externally of a tapering wooden box, narrow at the bottom and wide at the top or mouth, or *vice versa*, formed by sides inclining outwards or inwards, as the case may be, from the bottom at indefinite angles, according to circumstances. The circumstances on which the angles of the sides depend are, the curves of certain glasses to be fitted inside, and which may vary according to the effect intended to be produced. The interior of this frame is fitted with reflecting glasses varying in shape, and either flat or curved, or more or less in number, as the case may be, and which stand towards each other at suitable angles for producing the various effects stated. The effect generally stated is, that all objects viewed in this apparatus appear multiplied more or less in proportion to the number and power of the reflecting glasses used in its construction, and may be either enlarged, diminished, distorted, or presented in their natural forms according to the curves and shapes of the glasses. *Patent abandoned.*

103. D. and J. Tannahill. *Improvements in rivet-making machinery.* Dated January 13, 1863.

This invention is not described apart from the drawings. *Patent completed.*

104. W. Platts and J. Bailey. *Certain improvements in telegraphic cables.* Dated January 13, 1863.

This invention relates to a novel mode of protecting the wires employed in telegraphic communication, whereby the strain of any great length of cable is sustained by the covering or protection, instead of partially by the wire, as hitherto, and thus the continuity of the wire is preserved. The improvement consists in surrounding or enclosing the wires in a metallic tube or case formed in short lengths, every alternate length being formed like a ball at each end, the intermediate lengths being formed like a cup or socket, which are to enclose the balls, and all these lengths are to be made in halves (in the direction of their length) and bolted together or otherwise secured at their edges, so that, when they are so secured together with the balls in the sockets to form the joints, they will constitute a flexible tube, enclosing the wires, which will not gradually elongate by strain, as the twisted wire covering now employed. *Patent abandoned.*

105. J. T. Stroud. *Certain improvements in fixed and portable lights for domestic and other uses, applicable for burning gas and the mineral oils or spirits now so commonly used.* Dated January 13, 1863.

This invention consists—1, in the manner of constructing the parts of chandeliers, and brackets for receiving the burners and glass shades, and consists in supporting between the arms the part for holding the burner and glass shades, in contradistinction to fixing the supports for carrying the glass shades, chimneys, gallery, &c., on the ends of the arms, thereby cumbering the light with its obstruction, and consequent downward shadow. 2, in conveying the gas to a ring in which are circular or other formed openings or bearings (one mode for receiving the glass shades), thus producing the same result as last described, namely, the dispensing with all downward shadow by the removal of all metal work below the opening or bearing that supports the glass shade. 3, the patentee connects the ring for holding the aforesaid glasses to the body of the chandelier, or other suitable part of it, or by only inserting the cock or tap between them; by this method he dispenses with the usual arms, and thereby casts no shadow, and introduces an inexpensive mode of production. 4, in so constructing gas chandeliers that, while the principal lights are fixed or made to slide when desirable, the one centre light shall be fitted with an independent slide, so constructed as to admit of being considerably lowered from the other lights, thus possessing the quality to permit being down for lighting a table that may be placed beneath it, or other desirable purpose for which an increased or near light may be required. 5, in constructing a gas pendent light so that the same may be raised or lowered with weights as a counterpoise, and a water slide so constructed that the water shall not be subject to undue evaporation arising from its being placed immediately over the flame or light. 6, in the application to gas chandeliers and brackets of glasses or shades into a band, the lower part being inserted from the top; and, by preference, he supports it on two opposite radial pins that permit the shade to be pushed aside for the purpose of lighting, extinguishing, or regulating the flame. *Patent completed.*

106. C. H. Townsend and J. Young. *Improvements in compositions for preventing incrustation and corrosion in steam boilers and condensers.* Dated January 13, 1863.

These compositions may be applied in a state of powder or liquid, and they consist as follows:—1, Valonia, bark of the cork tree, and shumac; 2, Valonia and bark of the cork tree; 3, bark of the cork tree and shumac. The proportions of the above several compositions may be varied according to the water used in the boilers. *Patent completed.*

107. R. A. Brooman. *Improvements in machinery for lifting bobbins off spindles in spinning machines, and in lubricating spindles.* (A communication.) Dated January 13, 1863.

In spinning machines of the ordinary construction each bobbin has to be moved separately from its spindle, which entails a great loss of time where the operation has to be repeated many times a day. Now the object of the first part of this invention is to withdraw or raise a number of bobbins from the spindles simultaneously. There is a bar extending along the front of the machine, in which slots are formed to allow of its working up and down. The slotted bar is attached to a rack, in gear with a pinion, mounted on a shaft with a lever at one end connected to it. By moving the lever the pinion revolves, the rack and bar move in an upward direction, and the bar carries the bobbins with it, and lifts them up the spindles. The second part of the invention consists in fitting a box to the front of the machine for containing some lubricating material through which each spindle passes. *Patent completed.*

108. W. Southwood. *Improvements in machinery for manufacturing nails and brads.* Dated January 13, 1863.

This invention has reference to a previous patent dated May 13, 1862. The object of the present invention is that for the purpose of partly or completely forming that class of nails termed brads, the inventor employs a cutter or cutters of peculiar form, which will either cut, or cut, stamp, or press two brads at one time from slit bars or other forms of metal. The form of this cutter is varied as may be required, but its general features consist in forming a rebate upon the cutting edge, by which means both nails are cut by the under side of the cutter, one nail being stamped also by the under side of the cutter, whilst the second is stamped by the under side of the rebate. He can use with these cutters all or only a portion of the mechanism that is described in the specification of the former patent (May 13, 1862). *Patent abandoned.*

109. M. Tildesley. *Improvements in the manufacture of padlocks, and other locks and keys.* Dated January 13, 1863.

This invention consists—1, in coating all the parts of padlocks, except the spring, instead of making them of sheet or forged metals. 2, in a method of securing the shackle between the back and front plates to avoid employing the rivet pin. This the inventor effects by casting a sinking upon either side of the heel of the shackle, and a corresponding stud or rise upon the front and back plates, or a hole or a sinking in these plates with a stud or pin upon the heel of the shackle. 3, in forming a stop upon the cheek through which the bolt strikes, and against which stop the spoon of the shackle rests. 4, in such locks as usually employ a drill pin, he forms the key with a pointed end fitting a corresponding cup cast in the lock around which is a circular ward to receive the key. *Patent abandoned.*

110. C. E. Amos. *Improvements in machinery for the manufacture of paper.* Dated January 13, 1863.

In carrying out this invention, the knots and other extraneous matters which accumulate below the straining surface or knotter plates are drawn out or removed by means of a pump, or other analogous contrivance, and are conveyed into an ordinary knotter, which is to be used for the separation of such knots and extraneous matters from the fine pulp which may be drawn out or removed therewith. The fine pulp will then be allowed to flow back into the other or first knotter beneath the knotter plates, through which it will pass and be conducted into the paper machine while the knots will remain on the top of the knotter plate of the second or ordinary knotter, and may be readily removed therefrom by means of a skimmer or slice. By this arrangement of parts, there will be but little necessity for stopping the machinery in order to cleanse the knotters, and the work may therefore proceed uninterruptedly. *Patent completed.*

111. L. Lescuyer. *Improvements in india-rubber overshoes or goloshes.* Dated January 13, 1863.

This invention consists in the complete suppression of that which in an ordinary india-rubber overshoe or golosh constitutes the heel and waist, leaving the overshoe or golosh consisting only of the front half of the sole with its upper. The upper is made to come up very high, and terminates at the sides in two eyelets, each fitted with two double buttons, serving as pivots for two bands of elastic india-rubber fabric, which serve the same purpose as the straps of skates—that is to say, the said bands attach the overshoe or golosh securely to the foot, the bands being crossed one over the other behind the heels. The inventor also, according to this invention, lines or trims the improved india-rubber overshoes or golosh with fur, or the skins of animals with the hair on; and this part of the invention is also applicable to india-rubber overshoes or goloshes of other construction. *Patent abandoned.*

112. T. Butler. *Improvements in the manufacture of lace in twist lace machines.* Dated January 13, 1863.

For the purposes of this invention the warps or longitudinal threads of which a lace is to be composed are arranged in sets, in order that each set may be woven into a band or narrow weaving by means of two carriage threads, which is caused by the shogging of the way threads composing a set to pass alternately under and over the neighbouring warp threads, so as to produce tabby weavings. In addition to the longitudinal warp threads composing a set, and the two carriage threads which are employed to weft the same into a narrow tabby weaving, there is an additional way thread which is caused to be laid in a zig-zag direction to and fro across one surface of the narrow fabric produced as above explained, and such zig-zags of this warp are fastened to the surface of the weaving by causing the zig-zag warp thread to link or twist with the two carriage threads alternately. The warp threads composing the neighbouring bands or narrow weavings are at intervals (according to the pattern of lace desired to be produced) caused to be connected or to pass across each other, and in order to produce purls or loops on either edge of the band the zig-zags of the extra warps are caused to extend beyond the width of the bands or narrow weavings, and they are retained by threads which are afterwards withdrawn. *Patent abandoned.*

113. J. B. Rock. *Improvements in apparatus for saving life and property from fire and other danger in buildings and mines.* Dated January 13, 1863.

In constructing portable fire-escapes the patentee employs a tube constructed by preference of sheet iron, and mounted on a suitable wheeled carriage. At the upper and lower ends of the tube are rollers mounted on axes, and over these rollers endless chains pass, or a single chain may be employed, but this is not advisable. On the axis of the bottom roller cranked handles are fixed, by means of which the rollers can be made to rotate, and the chains to travel. These endless chains do not occupy the centre of the tube, but are placed on one side thereof, and at intervals apart there are brackets or steps hinged to the chains in such a manner that they fold down parallel to the chains when they are passing between the chains and the side of the tube adjacent to them, but stand out from the chains at right angles when passing on the other side of the chains. At the top of the tube is a small gallery or platform surrounded by a guard of wire work or other material. When the apparatus is employed for saving life or property from a burning building, the tube is set up against the wall of the building with its upper end near to a window. A man in charge of the apparatus then enters the lower end of the tube, and the cranked handles being turned by other persons he is, whilst standing on one of the hinged brackets or steps, wound up to the top of the tube; he lands on the gallery or platform at the top of the tube, and is then ready to receive from the window either persons or property, as the case may be. These he places on the brackets or steps of the endless chains, which are then by the persons at the crank handles below caused to travel, so as to lower the persons or property safely to the ground, the tube the meanwhile serving to prevent the possibility of their falling. *Patent abandoned.*

114. H. Bessemer. *Improvements in the manufacture and treatment of malleable iron and steel, and in furnaces, machinery, and apparatus employed in such manufacture.* Dated January 13, 1863.

This invention is described apart from the drawings. *Patent completed.*

115. J. Kidd. *Improvements in apparatus for measuring the quantity of gas supplied to single burners, and increasing its illuminating power.* Dated January 14, 1863.

The principal object of this invention is to determine the correct amount of gas consumed by public or private lights

in a given space of time, where a gas meter or registering apparatus is not in use, and the invention is carried out as follows:—Between the nib or burner and the gas regulator the inventor makes an adjustable aperture or hole for the passage of a certain quantity of gas; this hole is so arranged that it cannot be tampered with by the consumer when the apparatus is in operation; so that the gas passing through this hole at a regular pressure, no variation can occur in the quantity of gas passed through the apparatus in a given space of time. It is necessary in adapting regulators in connection with this adjusted aperture for measuring gas that this regulator should be so arranged as to give out the gas at a very low pressure, say from 3 to 5-10ths. By this means the regulator is always in action, even when the pressure is reduced to the lowest point, and the gas being consumed at this low pressure must necessarily pass through a nib or burner with a large opening, so as not to cause the check of pressure between the adjusted hole or aperture of the burner. The regulator for the purpose of this invention is formed with a valve and disc balanced or floated by the pressure of gas; the valve suspended to the centre of the disc opens and closes an aperture for the passage of the gas as the pressure varies. The disc may be made to float in mercury, or it may be composed of leather, or other suitable substance. *Patent abandoned.*

116. W. PIDDING. *Improvements in the soles and heels of boots and shoes, in stud nails, tips, and toe or other plates used therewith, and in placing and securing them.* Dated January 14, 1863.

In carrying out this invention, the inventor forms the inner soles and heels of boots and shoes of divisions of any non-elastic or non-pliable or pliable material or compound, such being perforated for the purpose of ventilation, or not perforated; and he places and fastens in any way between each such division other divisions of any elastic or pliable material or compound, to allow of their bending by the action of the foot when walking, and for the purpose of economy by using cheap materials or compounds in their manufacture. Or he forms the inner soles and heels of boots and shoes of perforated leather, or any elastic or other pliable material or compound. He forms some of the studs, nails, tips, and toe or other plates of stone, metal, wood, bark, porcelain, stone ware, glass, papier maché, cement, plaster of Paris, or any plastic material, concrete, shell, horn, bone, cork, leather, imitation leather, pith, resinous gum, or of any compound thereof. *Patent abandoned.*

117. J. A. SCHLUMBERGER. *An improved process for manufacturing colours for dyeing and printing.* (A communication.) Dated January 14, 1863.

In order to produce a true light blue which will appear blue at night as well as by day, the inventor takes a salt of rosaniline, such as hydrochlorate of rosaniline, and he mixes it with a suitable proportion, according to the shade required, of acetate of aniline, or an acetate of toluidine, or an acetate of any aniline homologues. In practice he mixes the rosaniline with three parts of aniline, and one and one-half part of acetic acid; he then neutralizes the mixture by adding thereto an equivalent proportion, say one part, of carbonate of soda, or soda, or any alkaline base which is able to decompose the acetate of aniline and produce a combined salt with the acetic acid used. The mixture is then heated to a temperature between 180 deg. and 210 deg. centigrade, as long as is requisite, in order to obtain the desired shade of blue, and until the mixture when looked at through a glass appears without any purplish tint. The product thus obtained is precipitated with strong muriatic acid, and is boiled up therein, when the blue colour will separate from the liquid, and will solidify it, so that it may be removed from the liquid by a skimmer. The colouring matter obtained may then be purified from the acid by boiling it several times in water, after which it may be pressed and dried. The colouring matter dissolved by the strong acid is precipitated with water, and will produce a blue of second quality, but no purplish or violet tint will appear. The colouring matters may then be dried, and will be ready for use if dissolved in alcohol or methylated spirit, and the shade produced is a blue which has no purplish tint by artificial light, but is a pure blue. *Patent completed.*

118. J. S. BUTLER. *Improvements in the manufacture of bobbin net made on bobbin net or twist lace machines.* Dated January 14, 1863.

The patentee claims—1, the manufacture of lace or bobbin net on twist lace machines, by causing three carriage or bobbin threads to work as weft threads, and twisting them together externally of the weavings; 2, the arrangement and combination of carriage threads and warp threads, or of carriage threads, warp threads, and gimp threads, in such manner as to produce net of any gauze less than the actual gauge of the machine on which it is produced. *Patent completed.*

119. G. T. BOUSFIELD. *Improvements in machinery for rolling, grinding, and cutting files.* (A communication.) Dated January 14, 1863.

This invention is not described apart from the drawings. *Patent completed.*

120. G. A. BIDDELL. *Improvements in machines for pulping turnips and other vegetable substances.* Dated January 14, 1863.

This invention relates to a class of machines known as root pulpers, having teeth or cutters projecting from the surface either of a disc, cone, or cylinder, which cut or tear the roots into mince or pulp. The improvements consist in so arranging the teeth or cutter of the machine that some of them shall project further from the surface of the disc or barrel to which they are attached than others, and so fixing them relatively to each other that those projecting the least shall not cut away the portions of the substances to be operated upon which have been left uncut by the longer teeth or cutters. By this improved arrangement of the teeth or cutters, the root or substance under operation is not allowed to rest idly upon the surface of the disc or barrel carrying the teeth or cutters, a defect in the action of all this class of machines as hitherto constructed. The teeth or cutters which project the furthest from the surface of the disc or barrel are made to pass between fixed projections, by which means the pulp is more evenly formed, and no large pieces of the substance under operation allowed to pass and mix with the pulp. The teeth or cutters are kept clean and prevented from clogging by means of a revolving brush or other suitable contrivance. *Patent completed.*

121. B. BURROWS. *Improvements in looms used in weaving narrow fabrics.* Dated January 14, 1863.

For the purposes of this invention, in order that shuttles of less length may be employed than have heretofore been necessary in weaving a given width of fabric, and so to admit of a greater number of fabrics being woven in a loom of a given width than has hitherto been possible. The patentee employs springs to each shuttle, which springs may either be fixed to the shuttle or to the batten, and each of such springs is arranged to act on that end of the shuttle which is still in the groove or slot in the batten, so as to counteract the tendency of the other end of the shuttle to drop as it passes across the space where the reed is situated, and before such other end of the shuttle has entered, and is supported in the groove or slot in the batten at the other side of the reed. In weaving narrow fabrics, it is common to employ two shuttles in making each fabric, and usually each shuttle has a reciprocating rack and a pinion to actuate it. The patentee employs only one reciprocating rack to actuate the pair of shuttles, and he employs therewith two toothed wheels to each pair of shuttles. The reciprocating rack gives motion to the two toothed wheels, and they give motion to two pinions, one on each side of the space in the batten where the reed is situated, and on the axes of such pinions there are two other pinions, which take into the racks of two shuttles. *Patent completed.*

122. J. LAWSON. *Improvements in apparatus for holding castings and other pieces while being planed or shaped.* Dated January 14, 1863.

This apparatus consists of a base plate, on which a turntable is mounted, and on the turn-table is a standard with its face perpendicular to the plane in which the turn-table rotates. The castings or pieces to be operated on are bolted to a slide which is capable of traversing the standard. The turn-table is rotated by means of a crank handle giving motion to spur wheels or gear, and the slide on the standard is caused to traverse, by preference, by a screw, which is also rotated by means of a crank handle acting with bevelled gear or otherwise. The apparatus may either form part of a planing or shaping machine, or may be separate therefrom, and with the pieces or castings upon it may be placed opposite the planing or shaping machine when work is to be done. The power which this apparatus gives of rotating the castings or pieces in front of the tool of the machine, and also of raising or lowering the castings or pieces, will allow of many different parts of the castings or pieces being brought within reach of the tool of the machine, without resetting the work; and, if desired, horizontal and vertical planing may be done at different parts of each casting or piece; and the apparatus ensures the truth of these several planings the one with the other. *Patent completed.*

123. E. MOREWOOD. *Improvements in the manufacture of coated metallic sheets or plates and pieces, and in apparatus to be used therein.* Dated January 14, 1863.

One part of this invention consists in making use of more than a pair of rollers working in or in contact with flux, such rollers being so arranged in relation to one another as to convey the sheets in the desired direction, and to accomplish one or both of the above-mentioned points by equalizing or reducing the coating metal on the surfaces of such sheets or plates whilst passing between them. The end of the sheet which slopes downwards on first entering is upward on leaving the flux. Another part of the invention consists in causing such sheets or suitable pieces, coated or in process of being coated, to travel between rollers working in contact with flux contained in two baths or vessels. The rollers and machinery in the two vessels are mechanically combined, so as to give the sheet a continued travel by the aid of machinery from the rollers of the first to and through the rollers connected with the second vessel. The object of the double bath is to enable the patentee to have the flux in two vessels at different temperatures, and to allow the sheet to lose a little of its heat in passing from the first bath to the second. Another part of the invention consists in arranging the screws and bearings of the pair of withdrawing rollers working at or near the surface of the flux, so as to enable the patentee readily to raise or depress such pair of rollers, so as to suit the varying thickness or size of the sheets which have to pass between them. *Patent completed.*

124. G. HOLT. *Improvements in apparatus for sweeping or cleaning chimneys, and also in apparatus for preventing chimneys from smoking.* Dated January 14, 1863.

For sweeping or cleaning chimneys, the inventor fixes a bar across the chimney at its lower end; this bar forms a step or support for an axis passing from top to bottom of the chimney. This axis is jointed at intervals, so that it may follow any bends there may be in the chimney, and it has hoops fixed on it at distances apart, which, resting against the sides of the chimney, keep the axis central, or nearly so. There are also fixed to the axis, at distances of a few inches apart, springs of thin metal sufficiently long to bear against the sides of the chimney, so that if the axis be caused to rotate, and at the same time to traverse slowly a short distance lengthwise of the chimney, the springs will come in contact with any part of the interior surface of the chimney, and will effectually remove any soot which may have lodged thereon. *Patent abandoned.*

125. T. WILKINSON. *Improvements in the manufacture of tubular steam boilers.* Dated January 14, 1863.

Heretofore, in constructing tubular steam boilers, the tube plate of the boiler which receives the tubes at the firebox end of the boiler has had holes made through it, through which the ends of the tubes have been passed. According to the present invention, the patentee forms around each hole in the plate a short tube, which projects out from the back of the plate, and on the exterior of each of these short tubes a screw thread is cut, in order that the ends of the tubes may be screwed on to them. The tube plate may be made of wrought iron or steel, or of copper or alloys of copper. *Patent completed.*

126. W. JOHNSON. *Improvements in the manufacture of chlorine and bleaching powder, carbonate of soda and soda-ash, and sulphate of iron.* (A communication.) Dated January 14, 1863.

This invention is not fully described apart from the drawings. *Patent completed.*

127. H. TURNER. *A process or mode of preventing and curing blight, decay, disease, and rot in potatoes, and other garden and farming produce.* Dated January 15, 1863.

This apparatus for preventing and curing blight, decay, disease, and rot in potatoes, consists of covers made of light framings of wood or metal, with calico or other suitable material stretched over them. The covers are made semi-circular, or of such a shape that, when the plants are covered, the atmosphere is excluded at the sides as well as from above. When the potato plants are covered in this manner, it is desirable to cause a current of air lengthwise under the cover, and this is produced by closing one end of the cover, and inserting a pipe or flue at the closed end, which pipe or flue is in connection with a heated flue or chimney, thereby rarefying the air, which produces the desired current under the cover; or the current of air may be produced in any other manner. These covers may be used at any time when the plants are liable to be injured by atmospheric influences. *Patent abandoned.*

128. W. HULSE and C. L. HAINES. *Improvements in machinery for the manufacture of taper metallic tubes.* Dated January 15, 1863.

This machinery is constructed as follows:—A taper mandril of the size of the taper tube to be made has a straight narrow slot made in its whole length, the said slot having the depth of about half an inch. The mandril fits in a bed which covers the lower half of the mandril, and a cover which partly covers the upper half of the mandril is capable of being fixed upon and removed from the before-mentioned bed. When the mandril is enclosed by the bed and cover, about three-fourths of the mandril are covered. The mandril is capable of being geared to driving mechanism, by which a slow rotary motion is given to it. In using the machinery, the taper mandril is placed in the bed, and the cover is fixed down. The edge of the sheet of metal to be made into a taper tube is introduced into the slot in the mandril, and the mandril is geared to the driving mechanism. As the mandril slowly rotates, it draws the sheet of metal between the mandril and the bed, and bends it into the form of an open-jointed taper tube. The cover serves to hold down the mandril, and also helps to bend the sheet of metal. After the mandril has made about two rotations, the figure of the tube is sufficiently perfect. The mandril being thrown out of gear with the driving machinery, the cover is removed, the cover lifted from the bed, and the taper tube drawn from off it. The taper tube may be finished by soldering in the ordinary manner. *Patent completed.*

129. E. HOWES. *Improvements in railway, ship, and other lamps.* Dated January 15, 1863.

This invention relates to railway, ship, and other lamps in which the flame is surrounded by or enclosed in a case to protect the said flame from wind and wet. The said case is so constructed that a sufficient quantity of air is admitted to the lamp for combustion, the burner and other parts of ship, railway, and other lamps being arranged as to avoid a shadow underneath the lamp. *Patent abandoned.*

130. T. C. BARRACLOUGH. *Improvements in apparatus for cutting metallic tubes or pipes, or pipes or tubes composed of other indurate substances.* (A communication.) Dated January 15, 1863.

This apparatus consists of two metallic jaws—by preference made of malleable or other elastic description of cast iron or steel—hinged together at one extremity, and so formed near the hinge or joint as to receive the pipe to be cut at right angles to the cutter employed. To these jaws at the further end to the hinge two steel or wrought iron rods are attached. The cutter which is made of steel slides vertically through one of the jaws, and its cutting force or pressure may be adjusted by means of a thumb screw above it. The pipe to be cut is placed in the hollow made for its reception, the two opposite ends of the rods brought nearly together, and secured by a link, links, or other substitute, the said jaws being thus caused to hold the pipe, and the cutter is tightened thereupon. If now the pipe be held firmly in a vice, and the apparatus turned several times round in a direction at right angles to the axis of the pipe, the cutter will penetrate the material and dissever the tube. If the metal or substance of which the tube is made be very thick, more pressure is to be applied gradually to the cutter by means of the screw until it is cut through. *Patent completed.*

131. T. C. BARRACLOUGH. *An improved alarum apparatus which may be employed in connection with locks or other fastenings.* (A communication.) Dated January 15, 1863.

This invention consists—1, in a novel arrangement and construction of mechanism designed to give alarm or signal by means of a bell which is struck by a hammer connected by mechanism with the latch and handle when opening or closing doors, drawers, tills, or other such means of enclosure or security, in conjunction with a disengaging gear. A second part of the invention consists in the application or combination of the said alaurm apparatus with locks or other similar fastenings, and in an arrangement of apparatus whereby the said alarum may be disconnected from the lock when its use is not required. This invention is not described apart from the drawings. *Patent completed.*

132. J. HARROP. *Improvements in the treatment of organic, fæcal, and urinous matters for the purpose of deodorizing the same, and in the preparation of a portable manure therefrom, and in the treatment of ashes and other refuse of combustion to be combined therewith ... for improveme...*

in machinery to be employed in the manufacture of the said manure. Dated January 15, 1863.

The patentee claims—1, The employment and use of chloride of sodium (muriate of soda or common salt), but more particularly that description which adheres to the bottoms and sides of the pans used in the manufacture thereof, and which is known by the makers as "pancake," or "salt pan scale," as a deodorizer or disinfectant in the manufacture of manure, either alone or combined with resin, pitch, coal gas tar, bitumen, asphalte, soot, wood, or peat charcoal, which aforesaid saline substances are to be applied during the accumulation of the fœcal and various matters to prevent decomposition and the generation of noxious effluvia therefrom, in contradistinction to the use of oleaginous matter in combination with common salt for the same purpose. 2, The application and use of hot or cold currents of air, either separately or combined with the draught and smoke of the furnace-flues, for the evaporation of fœcal and urinous matters. 3, The combination of parts forming the apparatus for evaporating, desiccating, or drying the excrementitious matters, as described. Lastly, the peculiar arrangement of the furnace and hot-air flues described, and the application of an exhaust pump, or of currents of hot or cold air, made as described. Also the novel arrangement and construction of a spiral rotating agitator, or a reciprocating perforated tubular one, of the form suitable to the shape of the boiler-pan or vessel employed, all as described and set forth. *Patent completed.*

133. G. GRAHAM and J. MCLEOD. *Improvements in apparatus to be used in Turkey-red dyeing.* Dated January 15, 1863.

This invention is not described apart from the drawings. *Patent completed.*

134. R. FERRIER. *Improvements in wet gas meters.* Dated January 15, 1863.

This invention relates to the construction of the wet gas meter in such a manner that the full supply of gas shall be maintained until the water in the meter from any cause falls below its proper level, when the continuous supply shall be effectually checked, and, if water be not supplied, shut off altogether. Also to an arrangement of securing the steady working of the fountain water, combined with a simple plan for regulating the meter to the standard measures, and the constructing of the meter and the waste water chamber so that no gas can be extracted unless first registered, and so that the water in the waste water chamber may be partly used to saturate the gas, and prevent it from drying up the water in the body of the meter. According to this invention a simple fluid syphon is applied on the entrance of the gas to the meter, so that no gas can pass unless the meter be filled to its proper level with water or other fluid, which also brings the syphon into action. *Patent completed.*

135. L. P. JOSSE. *An improved apparatus for cleaning wheat or other grain or seeds.* Dated January 15, 1863.

This apparatus consists of a shallow flat box, by preference of an equilateral triangular shape, formed of a bottom provided all round with a narrow rim (which box may, if required, be closed by a moveable lid, but which, by preference, is without such lid), so as to resemble a shallow equilateral triangular drawer, mounted either horizontally or in a slightly inclined or slanting position, with one of its corners pointing downward, on three or more feet of sheet metal, thin wood, or other suitable material of suitable flexibility for allowing the said box to receive a more or less rapid horizontal shaking, reciprocating, or to-and-fro motion in a direction parallel to that side of the box situated opposite the corner pointing downward. By this shaking or to-and-fro motion the grain and seeds, which from a hopper are allowed to fall into the said box, will be continually projected and thrown back from one to the other of the two remaining sides of the box, which will cause the chaff or lighter particles to rise towards the sides of the box situated opposite the above mentioned corner, whereas the grain or seeds or other heavier parts will be caused to advance towards this corner, and fall through an aperture provided in this part on to one or more perforated plates, screens, strainers, or sieves partaking of the motion of the box, in order to deprive the grain or seeds of any dust or foreign matters with which the same are contaminated; after this the cleansed grain or seeds fall into a proper receiver, whereas the chaff or lighter particles on the contrary rise on the top of the grain or seeds, and are caused to travel in an opposite direction to these latter, and take their exit from the box through a depression or aperture provided in that side of this latter situated opposite the above mentioned corner pointing downward, in case the box be situated in a slightly inclined or slanting position. The inside of the box is provided with one or more partitions and prismatic and other obstacles for conducting the grain or seeds, and for the better separation of the chaff or lighter particles from the same, whereas the dust or the heavy impurities—such for instance as small stones—are separated therefrom by the above mentioned strainers, sieves, screens, or perforated plates. *Patent completed.*

136. C. MURRELL. *Improvements in breech-loading firearms.* Dated January 15, 1863.

According to these improvements the inventor closes the breech-opening where the charge is introduced, by means of a short solid piece of metal about the size of the barrel at the breech, which is hinged thereto and folds up towards the muzzle in disclosing the bore. We cannot here quote the details of this invention. *Patent abandoned.*

137. J. P. BATH. *Improvements applicable to omnibuses, and other like carriages, to adapt them for use on rail or tram-roads, as well as common highways.* Dated January 15, 1863.

These improvements have for their object a simple arrangement whereby omnibuses and other like vehicles are rendered equally available for travelling upon rail or tramways or common high roads, and they consist in suspending by joints to the under side of the "fore carriage" two short pendulous arms, to the lower ends of which are attached axle-trees running parallel with the main axle-tree on the outside of these arms, and carrying thereon vertical revolving face plates, to the front of each of which is secured a disc, annular ring, or wheel, which, extending a short distance beyond the ordinary running wheels, acts as a flanch for keeping the bearing wheels on the rails. The inner ends of the axle-trees on the inside of the pendulous arms the inventor prefers, for the sake of strength, to bend upwards, and he attaches them to the centre of the main axle-tree by a suitable joint or joints. When the guides are in use, they are held in position by india-rubber or helical springs attached on each side to the lower end of the pendulous arms, and to the ends of cross beams or arms extending across the main axle-tree. When the carriage is required to run on the ordinary road, the guides are drawn up (by preference in a backward direction) by means of a bridle chain or cord and small windlass, or other mechanical equivalent, worked by the driver or other person. *Patent completed.*

138. C. H. G. WILLIAMS. *Improvements in the manufacture of colouring matters.* Dated January 15, 1863.

In order to produce a red colouring matter suitable for dyeing and printing, the inventor treats aniline or one of its homologues with the acetate of mercury. It is preferred that the aniline, or its homologue, should be employed in combination with acetic acid, as acetate of aniline (or of a homologue thereof), or it may be combined with hydrochloric or sulphuric acid, as a hydrochlorate or sulphate, or the aniline or its homologue may be employed in an uncombined state. The substances employed should be mixed together and heated until the colour is formed. *Patent abandoned.*

139. J. W. CHILD. *Improvements in means or apparatus employed in spinning and weaving.* Dated January 15, 1863.

Yarns to be used in weaving are spun upon tubes, which are usually of a cylindrical form, and such tubes have been formed of paper and other material. These improvements consist—1, in substituting for the cylindrical figure a polygonal figure, so that the outer surface of such tubes may be composed of a series of angles, and the patentee prefers that such angles be as sharp as possible by the surfaces between being hollowed. Such angles may be parallel or somewhat inclined across the axis of such tube, or slightly helical. Tubes thus formed will be found to fit more readily upon the wood or other internal tubes upon which they are placed during the spinning, as well as on the shuttle peg when in the shuttle, and the yarn as wound thereon will be more firmly held from slipping off bodily endwise, whilst it will also unwind or weave off more freely. He also applies to the ends of such tubes or receiver projecting rings of metal or other material to prevent the yarn in unwinding therefrom from catching on the raw edges or ends, as well as to enable such tubes to hold more yarn. He also forms tubes or receivers for yarn, when of a cylindrical or other form, with the outer surface thereof of differing diameter, by preference helical, and increasing in diameter towards one or both ends of them. He also forms such tubes with helical projections thereon. He also sometimes saturates or coats tubes when they are formed of paper with india rubber, or any other suitable matter adapted to resist the action of water or other liquid used to saturate the yarns thereon. These improvements relate, 2, to applying to the pins or pegs of the shuttles upon which such tubes are placed for weaving bands or rings of india rubber, leather, or other suitable elastic substance adapted to hold the tubes or receivers from slipping off. 3, The improvements relate to applying the washers upon which the flanges of the spools or spool tubes rest in spinning frames during the spinning, so that during the spinning, and as required, the amount of frictional surface exerted by such washers may be varied. *Patent completed.*

140. A. PRINCE. *Improvements in sewing machines.* Dated January 15, 1863.

This invention consists of certain mechanical arrangements whereby the fabric or material to be operated upon is propelled or moved along the needle plate by the motion of the needle bar, such motion being obtained by the action of screws or pins operating upon or against projections of metal, glass, or other hard substance, each presenting either an inclined plane or a curvilinear surface to the pins or screws, the projections being attached to and projecting from the front plate of the machine head, and set at the required angle. The invention further consists in the substitution of a needle plate of glass in lieu of metal for the purpose of allowing the operator to inspect the progress of the work, and also of an improved pressure foot. *Patent completed.*

141. W. E. NEWTON. *Improvements in microscopes.* (A communication.) Dated January 15, 1863.

This invention consists in a novel mode of constructing microscopes, whereby the observer is enabled to use the microscope in the same way as telescopes or kaleidoscopes are used. Instead of attaching the microscope to a stand which is placed on a table, and allowing the light to be thrown on the object by means of a glass or other mirror or reflector, the microscope may be used by holding it in the hands and looking through it with the object towards the light. *Patent completed.*

142. D. F. LEBLANC. *An improved level indicator or liquid gauge.* (A communication.) Dated January 15, 1863.

The glass tube indicators or gauges used to show the level of the liquid in steam boilers and other receivers placed under pressure have two principal defects—viz, their frequent breaking, which causes numerous accidents to happen, and the darkening of their sides, which renders their indications almost unperceivable. To obviate at once both of these defects the following combination is intended:—In experimenting with a rather thick-sided glass tube half-filled with water, the wide difference in refraction which exists between the full portion of it and the empty part thereof will be immediately noted or observed. On placing a screen with a circular hole of about two-thirds of the outside diameter of this tube behind that portion of the tube which is full of water, this circular hole will appear in the form of an ellipse, having its great or transverse axis perpendicular to the axis of the tube, whilst on the same screen being removed behind the empty portion of the tube, the ellipse assumes a rather lengthened form, having then its great or transverse axis parallel to that of the tube. It follows from this, first, that such a screen may be of avail to know—when no solution of continuity appears in the tube—whether this is quite empty or quite full; and, secondly, that however darkened its sides may be, unless they are altogether opaque, it will always be possible for any one to ascertain with its aid the presence or absence of the liquid inside. A metallic tube pierced from end to end with circular holes opposite to each other on two or three alternate diameters, and encasing the glass tube, may therefore become at once both a protection against breakages and their effects, and a means of more distinctly showing the height of the liquid inside. *Patent completed.*

143. R. A. BROOMAN. *Improvements in looms or machinery for the manufacture of lace and other fabrics.* (A communication.) Dated January 14, 1863.

These new points or features consist—1, In the employment of a chain mounted on fine bars, each of which is separately jacquarded as in the lever frame or machine, whereby the warp threads may be separately varied in the centre of the comb bars to the right and to the left at will, and also to a greater or lesser number of gates. 2, In the arrangement and employment of front and back comb bars, each separately jacquarded, capable of remaining fixed or of moving one or several times in the same or in contrary directions to the right or to the left, and that for a greater or lesser number of gates as required. 3, In fixing upon the back comb bars a number of pressers equal to the number of carriages, and each separately jacquarded, whereby all the carriages may be indiscriminately shifted. Besides the separate jacquarding of the pressers, the presser bar is also jacquarded in its general movement, so that it may either move or remain stationary. 4, In fixing on the front comb bars a number of pressors equal also to the number of carriages, but acting by one general movement, and allowing all the carriages without exception which may have been pressed forward to return upon the back bar. The bar carrying the front pressers is also jacquarded like the back bar—that is to say, it may be made to work or may be fixed at will. *Patent completed.*

144. J. KERR. *Certain improvements in retarding or stopping railway or other carriages.* Dated January 16, 1863.

This invention consists in connecting the ordinary buffer apparatus (consisting of buffer rods and draw springs) with the levers actuating the breaks, which may be effected by means of levers, links, or other equivalent connections, so that when the speed of the engine is slackened, the concussion or pressure of the buffers of the carriages behind shall compress the springs, transfer the impetus of the carriages to the breaks, and so stop the carriages. This may also be applied to carts or carriages on common roads, by connecting the straps, poles, or shafts by which the animal of draught retards the vehicle to breaks acting upon the wheels. *Patent abandoned.*

145. L. VERDURE. *Improved slubs or rovings (in flax, hemp, and other filamentous materials) produced by the slubbing frame and destined for fine spinning, as also for improved apparatus employed therein.* Dated January 16, 1863.

This invention consists in the employment of a rectangular steam chest provided with a steam-tight cover. In the said chest there are cross bars or trellises for supporting a number of bobbins covered with the slubs or rovings, and the bobbins are so placed that they do not touch each other. In the interior of the chest, near the bottom, there is a perforated pipe communicating by an outside pipe with a steam boiler; and at the lower part of the chest there is a pipe connected to a cistern or reservoir containing heated water or alkaline solution. When the bobbins are properly placed, and the chest covered, steam is admitted into the interior and kept in action so as to soak and heat the material on the bobbins, after which the steam cock is closed, and the water or solution is admitted to the interior to submerge the material for a time varying according to the nature and quality of the material, and when the water or solution is run off, and the bobbins removed, the slubs or rovings are prepared for fine spinning. By this process the gum resinous matters are removed from the material, thereby improving it in quality, and rendering it more easy to spin fine numbers, and at the same time diminishing the quantity of waste, and preventing the noxious effluvia caused by the fermentation which takes place in the ordinary troughs through which the slubs or or rovings pass from the creel to the drawing rollers of the spinning machine. *Patent completed.*

146. J. G. WINTER, and C. U. GRAY. *Improvements in vessels in which to cool and transport fatty or oleaginous matters, such as tallow, lard, palm oil, and the like.* Dated January 16, 1863.

Provisional protection has not been granted for this invention.

147. M. MOEGLEN. *Machinery for printing several colours in succession on the same surface.* Dated January 16, 1862.

This machinery consists of as many different rolls as there are to be colours in the patterns to be printed on the fabric. Each roll has engraved on it, or otherwise carries, the design it is to print; a separate colouring roller and apparatus for distributing the colour is provided for each of the printing rolls, as also a clothed roller for pressing the fabric against it. The fabric to be printed is first rolled upon a roller fitted at one end of the machine, it is drawn over a guide roller, then between the first printing roll and its pressing roller, whereby the design of such printing roll is printed say in blue; the fabric is then drawn between the second printing roll and its pressing roller, when, upon another part of the fabric not covered by the previous colour, the design upon the second printing roll is

...ated in a different colour, say red; and so on in succes... to receive the impression from as many printing rolls ...here are different colours in the pattern to be printed. ...tent abandoned.

...48. E. LOYSEL. *Improved apparatus for preserving valu... property, documents, and letters in cases of shipwreck,* ...ted January 16, 1863.

...n carrying out this invention, the inventor constructs ... safe or receptacle of iron, or other suitable strong ma...ial, and outside of this he places an outer casing, also of ...n, but much stronger than the inner one. A consider...e space is left between the two casings, and this space is ...ed, or partially filled, with blocks of some light wood, or ...her material, which will act as a stay between the two ...es, and will give great rigidity to the structure. In ...der to render these wooden or other blocks as light as ...sible, he first divides them in two, and hollows them ..., and then joins the parts together again, and secures ...em in their places between the casings. The safe may ... further protected externally by protecting hoops or rings, ...ich may be placed round the vessel, and will not only ...rengthen it, but will protect the casing from injury by ...mping on rocks when thrown overboard. *Patent aban...ned.*

149. W. SHORROCK. *Certain improvements in power ...ms for weaving.* Dated January 17, 1863.

This invention consists—1, in the novel and peculiar ar...ngement of apparatus for applying and regulating the ...wer or friction of the brake on the warp beam, whereby ...e inventor is enabled to keep a constant pressure upon such ...am during the operation of weaving; but should there be any ...perfection in the weaving, necessitating a reverse motion ... the warp beam, such reversing is accomplished without ...y pressure upon the beam by the said brake. A second ...rt of the invention consists in the employment and use ... bowls or pulleys secured below the healds and above the ...eadles, to which the healds and treadles are attached by ...eans of straps; such straps, when the treadles are in mo...on, partially warp or fold upon the above mentioned ...ulleys so causing by their connection with the healds a ...onstant rise and fall or shedding to such healds. These ...owls or pulleys act as intermediate carriers between the ...eadles and the healds, lessening the strain or weight upon ...e healds, thereby causing such healds to be more dura...le, also easier in their action upon the warps. *Patent ...bandoned.*

150. J. EDWARDS. *Improvements in the manufacture of ...uttons.* Dated January 17, 1863.

This invention is not described apart from the drawings. *...atent completed.*

151. J. LIGHTFOOT. *Improvements in printing and dye...ng textile fabrics and yarns.* Dated January 17, 1863.

This invention consists in the production of a black dye ...n textile fabrics or yarns by printing or staining them ...ith a salt or salts of aniline, or any analogous, homolo...ous, or isomeric compounds, mixed with certain metallic ...alts, or their oxides, as a mordant, as described. *Patent ...ompleted.*

152. J. ASHE. *Improvements in apparatus for pre...enting sea sickness.* Dated January 17, 1863.

These improvements in apparatus for the prevention of ...ea sickness are applicable both to suspended and balanced ...hairs, couches, and other supports for the person, and the ...bject thereof is to cause such chairs, couches, and other supports for the person to retain or remain in practically ...ne desired position, and counteract the rolling and pitch...ng motions of a ship at sea. *Patent completed.*

153. J. COMBE. *Improvements in machinery for spread...ng, drawing, and carding flax and other fibrous substances.* Dated January 17, 1863.

This invention consists in a new method for transposing fibres fed into the machine laterally, so that such fibres are presented endways in regular succession to the nip of a pair of rollers, which may either be delivering rollers, constituting a part of this machine, or may be the back rollers of a drawing frame, according to the manner in which the invention may be applied. We cannot here quote the details of the invention. *Patent completed.*

154. G. HAYCRAFT. *Improvements in powder flasks.* Dated January 17, 1863.

The patentee makes powder flasks with a hollow cylindrical screw stopper with a screw thread formed upon the outer side of it. This hollow cylindrical stopper closes the mouth of the flask, there being a corresponding female screw formed in the neck of the flask, and is closed at one end by a suitable head piece; it serves, when the flask is open, as a measure for the powder, it being made to contain one charge thereof. *Patent completed.*

155. G. T. BOUSFIELD. *Improvements in hot-air engines.* (A communication.) Dated January 17, 1863.

This invention is not described apart from the drawings. *Patent completed.*

156. W. E. NEWTON. *Improvements in the manufacture of buttons.* (A communication.) Dated January 17, 1863.

The special object of the present invention is to manufacture buttons in one piece, without soldering, by which means great strength is obtained, and the buttons are produced at a much lower cost and with greater expedition than by the ordinary means where the shank is soldered on. These results are obtained by the employment of special tools or apparatus which constitute the principle and essence of this invention, and which may be operated either by hand or by any suitable mechanical means, the different requisite operations being effected in succession, and in a determined order, for the complete manufacture of buttons in a single piece having a nearly spherical form. By means of the operations described in the specification of this invention, the buttons, of whatever metal they may be formed, are entirely finished without it being necessary to heat them, the metal being fashioned by successive operations in dies in a cold state, so that there is no risk of spoiling the material under operation, as is the case when it is heated by the soldering process. The invention cannot be described in detail without reference to the drawings. *Patent completed.*

157. E. SABEL. *Improvements in the manufacture of artificial stone.* (A communication.) Dated January 19, 1863.

The patentee claims the manufacture of an artificial stone by running molten cinder into large pits or moulds prepared for its reception (in the manner described in the specification), and in allowing the masses obtained to cool gradually. *Patent completed.*

158. C. NORTON. *Roughing horses.* Dated January 19, 1863.

In carrying out this invention the patentee takes a piece of iron of a fitting size and length, and turns it up at each end, proceeding first in a straight and then in a curved direction from the toe to the heel on one side, with holes at the toe and heal. The middle is riveted and bolted to another piece of iron in the centre, so as to be flexible and turned up at one end, with holes to screw in points of any size. Near their extremities, across the two pieces of iron, he fixes a bolt, flexible or otherwise, with a screw and nut at the end to widen or contract the before-mentioned two pieces of iron at the heel. *Patent abandoned.*

159. J. LAURIE. *Improvements in apparatus for churning milk and mixing liquid compounds.* Dated January 19, 1863.

In carrying out this invention, the inventor places a shaft in a horizontal position outside a vessel of any suitable shape or dimensions, and turns it by hand or power, and he places inside the said vessel any convenient number of dashers or beaters to revolve on bearings, motion being given to them by wheel gearing connected to the horizontal shaft, so that, when it is turned, the dashers revolve within each other, and in opposite directions, thus causing great agitation of the liquid or mixture, and, consequently, an economization of time and labour. *Patent abandoned.*

160. W. S. BROOKE. *Improvements in the manufacturé of insulators for electric telegraphs.* Dated January 19, 1863.

This invention refers to a previous patent, dated July 17, 1861, No. 1800. The inventor now substitutes for the ebonite cell mentioned in the specification of the former patent, a cell of hard and unvarnished papier maché, of the same shape as the ebonite cell, but thicker, so as to fit with strong friction into the iron cap, and to receive the iron pin also with strong friction. The several pieces are put together by lever pressure, the external cap being warmed so as to contract on cooling round the papier maché cell. The papier maché is thoroughly saturated with pure paraffine by being placed in a bath of this substance melted in a vacuum apparatus, by which all air is exhausted from the pores of the papier maché, and the liquid paraffine then forced in under a pressure of 100 lb. or more to an inch. He also employs plates of talc or layers of asbestos fibre within the iron cap, and between this and the papier maché cell, and also within this cell and between its internal surfaces and the central iron pin. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated April 22, 1863.

999. T. Settle, Bolton, spindle and flyer maker. Certain improvements in "flyers," to be employed in roving, slubbing, and spinning cotton and other fibrous substances.

Dated May 8, 1863.

1151. H. Schooling, 5, 6, and 7, North Side, Bethnal-green. Improvements in moulding or shaping lozenge paste or other plastic materials.

1154. J. H. Bailey, civil engineer, New York. An improved mechanical movement for producing an impelled current of air for lamps, and which may be used for other purposes. (A communication.)

Dated May 23, 1863.

1293. E. Barlow, Bolton, machine maker, J. Ashworth, jun., Turton, near Bolton, cotton spinner, J. Newhouse, Farnworth, near Bolton, manager, F. Hamilton, foreman, and W. Hope, carder, Bolton. Improvements in lap machines, for preparing cotton and other fibrous substances.

Dated June 3, 1863.

1385. E. A. Locke, Boston, United States. Improved means of securing identifying labels or tags to bales of fibrous material. (Partly a communication.)

Dated June 15, 1863.

1497. T. Petitjean, Geneva, Switzerland, chemist. Improvements in the manufacture of glass.

Dated June 25, 1863.

1603. W. Kirrage, 1, Victoria-street, City, surveyor. Using Apo elastikon hyphasma as a new and improved cloth for floors, roofs, walls, tanks, and other linings, being impervious to damp and of great strength and durability.

Dated July 2, 1863.

1649. W. Miller, 70, Upper Stamford-street, Blackfriars. An improved mode of evaporating through the combined agencies of heat and centrifugal force, and the machinery employed therein, more particularly applicable to saccharine solutions.

Dated July 6, 1863.

1673. J. Samuel, 26, Great George-street, Westminster, civil engineer. Improvements in the manufacture of gas for lighting and heating purposes, and in apparatus connected therewith.

1678. H. Caunter, Stornoway, Lewis, and county of Ross. An improved lubricating matter or composition.

Dated July 7, 1863.

1681. C. Schiele, 20, Milton-street, Manchester, engineer. Improvements in turbines.

1687. W. E. Gedge, 11, Wellington-street, Strand. Improvements in the construction of seats, chairs, sofas, lounges, and other similar articles of furniture. (A communication.)

Dated July 8, 1863.

1695. H. Armstrong, Whitby, York, alum manufacturer. Improvements in the manufacture of alum.

Dated July 9, 1863.

1713. W. V. Wilson, Jubilee-street, Mile-end, manufacturing chemist. Improvements in the manufacture of red colouring matter.

Dated July 11, 1863.

1735. A. Dixon, Harborne, Stafford, engineer, and J. Pumphrey, Birmingham, machinist. A new fastener or holder for flowers or other decorations to coats and articles of dress.

Dated July 13, 1863.

1743. R. D. Dwyer, Warrington, engineer. Improvements in the construction of letter copying presses.

1749. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in apparatus for suspending chandeliers, gaseliers, and other weights. (A communication.)

Dated July 14, 1863.

1765. J. L. Todd, Belfast, engineer and mechanic. Improvements applicable to the rollers of machines employed for spinning fibrous materials whilst in a wet state.

Dated July 16, 1863.

1785. C. Stokes, Leigh Sinton, Worcester, saddler. An improved expanding and contracting horse collar.

1787. J. Lamb, Kidderminster, machinist, and F. Tovey, auctioneer. Improvements in looms for weaving carpets.

Dated July 17, 1863.

1795. J. Darrieux, Candéran, France, merchant. Pounded glass powder for cleaning metals, and also for tooth powder.

Dated July 21, 1863.

1822. W. Clarke, Forest-road, Nottingham, lace manufacturer. Improvements in the manufacture of fabrics in twist lace machinery.

Dated July 22, 1863.

1833. J. Ronald, Liverpool, merchant. Improvements in apparatus for dressing or preparing for spinning hemp, flax, Manilla hemp, and other like fibrous material.

Dated July 23, 1863.

1840. W. Cole, carpenter and builder, 15, Wentworth-road, Bow-road. Improvements in apparatus for securing the safety of persons in window cleaning, or otherwise working outside of windows.

1841. A. T. Holden, Birmingham, manufacturer. Improvements in carriage and other springs.

1842. L. L. J. Fillion, 10, Rue de la Fidelité, Paris, glove maker. Improvements in apparatus for extinguishing chimney fires, and in preventing explosions.

1843. M. A. Soul, 3, Leadenhall-street. Improvements in expelling solid and liquid refuse matter from steam and sailing ships below the water line, applicable also for discharging cannon below water from ships and forts, and in part for charging gas retorts and iron furnaces, and for other similar useful purposes. (A communication.)

1845. W. and J. Garforth, Dukinfield, engineers. Certain improvements in preparing, beetling, or finishing textile fabrics, such as cotton, wool, linen, or other fibrous materials.

1847. W. Horton, Glasgow, gunmaker. Improvements in firearms.

1849. T. Perkins, Exchange-buildings, Hitchen, Hertfordshire, ironmonger. Improvements in horse rakes and hand rakes.

Dated July 24, 1863.

1851. W. L. Barnes, M.A., Norfolk. An improved method of breaking the speed of, and stopping, railway trains or other locomotive wheeled carriage or carriages, at the same time signalling to the driver, or for using the signal and break separately.

1853. T. Sturgeon, Belle Sauvage-yard. Improvements in chains.

Dated July 25, 1863.

1855. T. C. Bull and T. Morgan, Weobly, Hereford. An apparatus for collecting fruit from trees without injury.

1857. P. E. Gay, 5, Rue de Grenelle, St. Honore, Paris, contractor. Improvements in boring apparatus.

1858. J. Boyd, Glasgow, engineer. Improved mechanism for forming imitation selvages or longitudinal cords in weaving.

1859. F. Tolhausen, 17, Faubourg Montmartre, Paris. Improvements in the manufacture of gun barrels. (A communication.)

Dated July 27, 1863.

1861. J. W. Welch, Manchester, agent. Improvements in sizing and finishing fabrics, and in the machinery or apparatus employed therein.

1863. F. and L. Ford, Gloucester, manufacturers. Improvements in the manufacture of various articles with surfaces in imitation of different kinds of marbles or similar ornamental materials.

1867. J. Pain, Fort-street, Spitalfields, umbrella manufacturer. Improvement in the manufacture of umbrellas and parasols.

Dated July 28, 1863.

1873. D. Taylor, Bonchester-bridge, Roxburgh, joiner. Improvements in ventilating hay, corn, and other ricks, and in apparatus connected therewith.

1875. W. T. Smith, Dalston, engineer. An improved method of securing or tightening the cords of blinds and other rollers.

Dated July 29, 1863.

1877. P. H. Girardin, Paris. Improvements in lamps.

1879. G. Rickarby, 1, St. Giles's-road, and T. A. Barrett, 73, Observatory-street, Oxford. Improvements in window frames and sashes.

1881. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in cartridges. (A communication.)

Dated July 30, 1863.

1883. G. Inskeep, Madeley, engineer. An improved mill for grinding bones, grain, logwood, and such like substances.

1885. J. Boeddinghaus, Elberfeld, Prussia. Improvements in means or apparatus for the production of printed or particolored yarns.

1886. J. T. Stephens, Bridport, Dorset, gentleman, and C. Hoare, manager, Bridport. Improvements in ma-

chinery for the manufacture of yarns, threads, laid twine, and other cordage.

1888. W. Firth, Burley, near Leeds, merchant, and S. Firth, gentleman. Improvements in machinery and apparatus for working coal and other mines, and in apparatus for loading waggons or other vehicles.

1890. R. Hoe, Leadenhall-street, and H. J. Cole, New-street, Kennington-road, Surrey, packing case makers. Improvements in fastenings for packing cases.

1891. T. Apps, Lower Norwood, gentleman. Improvements in four-wheeled vehicles.

Dated July 31, 1863.

1892. W. and J. Graham, Burnley, machine makers. Certain improvements in looms for weaving.

1893. G. Sigl, Vienna, engineer. Improvements in the construction of force pumps.

1895. J. P. Culverwell, Dublin, gentleman. Improvements in railway lamps.

1896. J. B. Andreaux, 12, Rue Notre Dame de Nazareth, Paris, toy maker. Improvements in the application of steam to toy boats or other similar toys where steam can be employed as a motive power.

1898. J. F. Dickson, Bouverie-street, Fleet-street. Improvements in the manufacture of boots and shoes.

Dated August 1, 1863.

1901. W. Cotton, Loughborough, manufacturer. Improvements in the manufacture of looped fabrics, and in machinery or apparatus employed therein.

1902. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in dyeing mixed animal and vegetable fibres, whether in a raw or manufactured state. (A communication.)

1903. R. A. Brooman, 166, Fleet-street, patent agent. An improved warming pan. (A communication.)

1904. G. Taylor, Leeds, iron manufacturer. Improvements in shaping boiler and other plates, and in apparatus employed therein.

1905. J. Hoefler, Manchester, merchant. Certain improvements in the method of preparing and treating "Codilla fibre" and tow, to render them available as a substitute for cotton, or to be mixed therewith.

1906. J. Kirk, Burnley, overlooker of power looms. Certain improvements in looms for weaving.

1910. T. Fellowes and H. Hemfrey, Spalding. Improvements in apparatus for elevating straw and other agricultural produce.

1911. J. E. Vanner, Coleman-street. Improvements in the manufacture of umbrellas and parasols.

Dated August 3, 1863.

1912. E. A. Cowper, 35a, Great George-street, Westminster. Improvements in self-acting mules for spinning.

1913. J. W. P. Field, 233, High Holborn, gun maker. Improvements in the manufacture of sheaths or cases for staves or other similar weapons.

1916. H. Woods, Burton-upon-Trent, engineer. Improvements in the apparatus used for regulating the temperature during the process of fermentation in the "Union cask," "Tunning cask," or "Cleansing cask."

1917. J. Munro, 13, Melton-street, Euston-square. Improvements in apparatus for producing optical illusions.

Dated August 4, 1863.

1919. J. Abrahams, 9, Great Prescott-street, Goodman's-fields (East), watch manufacturer. Improvements in brakes for railway and other carriages.

1920. T. H. Baylis, 55, Mornington-road, Regent's-park, gentleman. Improvements in hawse pipes, mooring pipes, and deck chain pipes.

1921. G. Stevens, Malvern-cottages, Portland-place North, Clapham-road. Improvements in means or apparatus for effecting a regular supply of air or aeriform fluids for various purposes.

1922. S. Bury, Manchester, calenderer and finisher, and J. Price, engineer. Certain improvements in valves for steam engines.

1925. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in machinery or apparatus for moulding and casting hollow projectiles. (A communication.)

1926. E. Pace, Queen-street, manufacturer. Improvements in machinery for cutting splints for matches and for collecting the same.

1927. T. Pickersgill, Huddersfield, manufacturer of mill strapping for machinery. Improvements in machinery or apparatus for feeding wool, cotton, and other fibrous materials into machines for preparing the same for spinning.

Dated August 5, 1863.

1929. G. Clark, 30, Craven-street, Strand. Improvements in the construction and protection of ships, vessels, and floating batteries, and in the preparation and arrangement of materials for those purposes, some of such improvements being applicable to the construction and protection of land fortifications.

1931. W. Storer and J. Hancock, Nottingham, machinists. Improvements in electro-motive engines.

1932. C. Garton, Bristol, brewer, and T. Hill, sugar refiner. Improvements in evaporating and cooling.

1934. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. An improved mode of, and apparatus for, producing stereotype plates. (A communication.)

Dated August 6, 1863.

1940. J. Tenwick, Albion Iron Foundry, Clarendon-street, Portsmouth, iron moulder. Improvements in self-acting valves and traps for sewers.

1942. W. Clark, 53, Chancery-lane, engineer. Improvements in ovens. (A communication.)

1946. J. Kirkham, Euston-road, civil engineer. Improved apparatus for generating heat for smelting and other purposes.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, August 18, 1863.

872. J. Swinburne and J. Stanley. Steam engines and generators.

874. A. C. Bamlett. Reaping and mowing machines.

888. W. E. Gedge. Apparatus for propelling and navigating small craft. (A communication.)

889. W. H. Mitchell. Barometer.

896. G. Spence. Preventing incrustation in steam-engine boilers.

897. A. Hett and F. W. Bassett. Preventing the fouling of ships' bottoms, and cleansing the same when fouled.

905. G. Colomb. Manufacturing blocks of wood of diversified shades and hues proper for veneering and other purposes.

908. S. Shelmerdine and J. Dransfield. Ornamentation by printing of felt hats.

916. J. Lockwood. Steam boiler and other furnaces.

917. D. Mylrea. Fire bars or furnace grids.

919. J. Farrar. Twisting or doubling yarns of wool or other fibrous substances.

920. W. Clark. Separating ores from their gangues, and and in apparatus for the same. (A communication.)

922. A. F. Maclure. Looms for weaving figured fabrics.

923. C. A. Collins. Apparatus for loading carts and waggons with hay, straw, and other similar products.

925. J. Gill. Printing machinery.

932. T. Mallinson and P. Williams. Opening, cleaning, carding, and grinding or sharpening cards used in preparing cotton and other fibrous materials.

936. W. and J. Keats. Boots, shoes, or other coverings for the feet.

937. J. Combe and J. H. Smalpage. Machines for winding cops, &c.

938. J. Keats and W. S. Clark. Sewing machines.

942. J. Smith. Furnaces and boilers for the generation of steam.

952. A. V. Newton. Blowing apparatus. (A communication.)

953. T. B. E. Fletcher. Collecting the solid portions of sewage.

957. C. Terrett, Preventing incrustation in steam boilers.

961. T. A. W. Clarke. Shuttle driver and apparatus for working the same.

971. B. J. Webber. Separating corn from the ears, and for combing straw.

972. C. W. and F. Siemens. Furnaces which are chiefly applicable to the smelting of iron.

995. W. C. Cambridge. Construction of harrows.

1010. W. E. Newton. Repairing worn-out files and rendering them again fit for use. (A communication.)

1064. W. Clark. Manufacture of paper. (A communication.)

1223. W. Clark. Repeating firearms. (A communication.)

1267. J. T. Markall. Machinery for working of wood.

1454. C. L. Van Tenac. Railway wooden sleepers. (A communication.)

1619. G. Davies. Cork-cutting machine. (A communication.)

1661. J. C. MacDonald and J. Calverley. Manufacture and application of printing apparatus.

1693. W. Basford. Generating and purifying gas made from coal and other bituminous substances.

1758. J., G. T., and F. R. Holmes. Threshing and dressing machines.

1761. R. Hornsby, jun., and J. E. Phillips. Reaping and mowing machines.

1800. G. F. Wilson and G. Payne. Soap.

1878. N. Thompson. Apparatus for stopping the bung-holes of casks and similar vessels; also tools or implements for fixing and removing such stopping apparatus.

1890. R. Hoe and J. Cole. Fastenings for packing-cases.

1906. J. Kirk. Looms for weaving.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed August 15, 1863.

430. J. Gimson.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, AUGUST 28, 1863.

THE BRITISH ASSOCIATION.

The 19th century has been termed, with truth, the social age. It is an epoch of intercommunication; not alone of individuals, but of thought. The civilized world has never beheld such facilities as those afforded during the last sixty years, for the spread of information, the discussion of questions, or the advancement of the arts and sciences. To none of the societies which exist in England, on the Continent, or in America, is science more indebted for its advancement than to that Association which holds its annual meeting this week at Newcastle-upon-Tyne. From the moment of its formation, thirty-two years ago, the list of its members has embraced the greatest names known in almost every branch of science. The British Association has by its labours conferred national benefits which will be remembered long after the donors have sunk to rest; and the position to which it has attained by the truthfulness, accuracy, and value of its reports, and the ability with which its multifarious investigations are conducted, holds out fair promise of a vast extension of its powers in years to come.

The Association traces its origin to Dr. Brewster, who proposed its formation to the Yorkshire Philosophical Society in 1831. He pointed out the great advantages to be derived from the establishment of a National Association for scientific intercourse, to be formed on the German model; and his efforts were warmly seconded by Mr. Robinson, Mr. Forbes, and Mr. Johnson, of Edinburgh, and Mr. Murchison, of London. These gentlemen pointed out that there was no society in existence in Great Britain which pretended to collect observations on a regular system, or form a national catalogue of scattered particulars of any of the sciences. The Yorkshire Philosophical Society, in consequence of the representations of these gentlemen, became the nucleus of the British Association, which held its first meeting in the theatre of the Yorkshire Museum on the 27th of September, 1831, about 300 persons being present, circular letters having been addressed to thirteen societies in London, and twenty-six in the rest of England; Viscount Milton took the chair. Mr. Harcourt, in a kind of inaugural address, thus stated the views of the committee:—"It is proposed to found a British Association for the Advancement of Science, having for its object, to give a stronger impulse and direction to scientific inquiry; to obtain a greater degree of national attention to the objects of science, and a removal of those disadvantages which impede its progress; and to promote the intercourse of men of science with each other and foreign philosophers."

The mere recapitulation of the subjects to which the society has devoted its attention since its formation, would give but a feeble idea of the extent and value of its labours. The series of its printed reports extend to over 30 volumes, and yet they by no means contain a complete record of the works undertaken and conducted at the request and expense of the body. The complete reports occupy not less than 18,000 pages, much of the most valuable information being unfortunately placed out of the reach of the general public by the cost of publication. The amount of money granted for scientific purposes had reached to £20,000 in 1862; and the gratuitous labours of the members would, perhaps, be poorly represented by a vastly greater sum. Two-thirds of the money expended have been devoted to mathematics and physics, from the greater importance of the fields for inquiry presented by these departments of philosophy, and the immense cost of the requisite instruments, and expeditions undertaken to every part of the world. The nation owes to the labours of the Association the possession of three splendid catalogues of stars compiled during eight years, at an expense £1,800. Under the direction of Dr. Whewell, a laborious system of observation, obtained by the influence, and reduced at the expense of the Association, who have aided this work with a sum of about £1,300, has determined the course of the tide-wave in regard to the coasts of Europe, of the Atlantic, of the United States, of New Zealand, and of the east coast of Australia.

The Kew Observatory was presented to the Association by Her Majesty in 1842. Erected by George III., it had been long left useless. Such a donation proved a positive boon. It gave to the society a fixed position, as well as a depository for instruments and papers. The society has in return conducted the establishment with a skill and energy which have raised it to a national importance. All the money which could legitimately be spared from other pursuits has been devoted to the construction and purchase of instruments, and the advancement not only of pure astronomy but also of those kindred departments of science which are not less important, although presenting themselves less prominently. For example, all the barometers, thermometers, and hydrometers required by the Board of Trade are admirably tested, and standard thermometers are graduated, magnetic instruments are constructed, and their constants determined for foreign or colonial observatories. The various expenses connected with this establishment have absorbed about £6,000. The annual allowance for the past seven years having been £500. The suggestion of Sir John Herschell in 1857, that daily photographs should be taken of the sun, led to the construction of the rather remarkable instrument known as the Kew photoheliograph, under the directions of Mr. De la Rue. The British Association lent its aid by the completion of the instrument in 1857, at its workshop in the Observatory, and by giving it a place in the dome. This instrument did good service in Spain during the eclipse of the sun in 1860.

There is scarcely a department of science to which the Association has not devoted considerable attention; and many scientific expeditions have been proposed, undertaken, and conducted to a successful conclusion by its almost unaided efforts. The magnetic survey of the British Islands, commenced and executed from 1834 to 1838, was conducted by a committee of its members—General Sabine, Professor Phillips, Sir J. Ross, Mr. Fox, and Mr. Lloyd, acting upon a suggestion brought before the Cambridge meeting in 1833. The recommendation of the Association, that a Government expedition should be organized to make a magnetic survey in the southern portions of the Atlantic and Pacific Oceans, gave rise to the voyage of Sir James Ross in the years 1839 to 1843; the completion of this survey in 1845, by Lieutenants Clark and Moore; and the magnetic survey of the Indian Seas, by Captain Elliott in 1852, completed, between 1855 and 1858, by Messrs. Schlagintweit.

The importance to our shipping interests of the results obtained, can scarcely be over-estimated; nor did the society rest here, but continuing its labours, the year 1840 saw the establishment through its exertions of the system of simultaneous magnetical and meteorological observations, since well carried out by our own and most of the principal foreign Governments. The sum of £900 was expended between 1840 and 1844 on an important series of experiments, principally carried out by Mr. Scott Russell, on waves. The results, though ready for the press long since, have never been published from want of funds; the great difficulty which hampers most of our societies. Experiments on the strength of materials, the relative strength of hot and cold blast iron, the effect of temperature on their tensile strength, on the effect of concussion and vibration on their internal constitution, carried on principally by the late Mr. Eaton Hodgkinson, at different intervals from 1838 to 1856, have been aided by grants amounting to £400; while botany, zoology, and physiology have absorbed about £1,400, of which nearly £900 has been applied to zoology.

It is impossible to carry our detail further, when speaking of an association so energetic, and so long established. To this and other bodies of scientific men bound together by like ties, England owes much of her supremacy. France, it is true, is distinguished for the eminence of her mathematicians, her chemists, her philosophers. In no nation do we meet with more learned bodies than those who discuss science in her principal towns. The other nations of the Continent are scarcely behindhand in this respect, yet none of these have brought about results tending so generally to national advantage as our own societies—a fact which may perhaps be attributed to the differences in the national character and disposition; our philosophers preferring to deal with and devote their attention to the applied sciences, rather than to those interesting abstractions, for they are little else, in the profound consideration of which our neighbours take so much delight. The British Association affords us an example of a body of men, who, without neglecting science in its most abstract form, have studied it chiefly, in order to its application to our wants as a people. Its members have explored the air, the earth, the heavens; and deriving information on all sides, have communicated it with no niggard hand. Such associations stimulating and aiding each other, tend more to the advancement of knowledge than the labour of thousands of isolated individuals. Union is indeed strength when it exists between philosophers.

We give, elsewhere, an abstract of certain portions of the address delivered by Sir William Armstrong, on taking the President's chair on Wednesday evening. With the speech we are disappointed. From its perusal we have arisen with a feeling of disatisfaction. Sir William supplied his hearers with a Barmecide's feast of knowledge; and we question if any one present felt his appetite, we will not say for knowledge, but for information, satisfied as he could have wished. We are well aware of the extremely difficult task which the composition and delivery of a speech of the kind involves; but the greater this difficulty, the greater the honour to him who successfully overcomes it. Sir William Armstrong's speech contains not one original suggestion of the slightest value; and, as a recapitulation of the progress made by science within the last twenty-five years, it is extremely superficial. In dwelling on mechanical science, he has scarcely been orthodox—a circumst[illegible] we would have passed over had he [illegible]

which he was not. Taking, apparently, the steam-engine in its present imperfect form, Sir William, echoing old theories, more than hints at the possibility of producing machines capable of developing power with much greater economy. It requires little calculation to show how erroneous are such conclusions, when we reflect that much less than one-half pound of coal can produce a horse-power per hour in theory, and that 1·5 lb. has done so in actual practice, we can easily conceive how unlikely it is that the steam boiler and furnace will be superseded by the electrical battery. At a time like the present, when it is of the last importance that we should reduce the size and weight of our engines to the lowest possible limit, it is folly to predict the introduction of the cumbrous and unwieldy caloric engine. Sir William's speech, however, if it has done no good, is not likely to do harm; and with such a conclusion we must rest content.

WELDING BOILER PLATES.

THE march of improvement in the formation of plate iron structures is decidedly slow. New forms of wrought-iron bridges present themselves daily. Novelty in external shape, and internal arrangements, can easily be found in our iron ships. Steam boilers appear under a thousand varied shapes; patents are taken out continually for improvements in fire-boxes, in flues, in grates, in boilers themselves, and in everything which appertains ever so remotely to them. But the actual method of putting a wrought-iron bridge, or a ship, or a boiler together—of fastening and combining their parts so as to render each a complete structure—remains in much the same state in which it existed 50 years since. A working boiler-maker who was considered skilled in his trade in the days of Watt would, we imagine, experience little difficulty in maintaining his reputation in the present day, for, of all trades, this perhaps has progressed least. The old waggon or haystack boiler was put together by rivets, in precisely the same way that the modern mechanic builds up that of a first-class locomotive, and for all that we can see, the rivetted joint will be as habitual in fifty years as it is now. The prevalence of a custom goes for nothing as a proof of its necessity or its correctness. The endurance, and well-nigh universal adoption, of a certain principle of construction, for years, is no evidence whatever that it may not be superseded with advantage; and it is high time that boiler construction, leaving aside ships and bridges for the present, should partake of some of the changes and improvements which the advance of the arts place at our disposal.

The employment of rivets for securing metal sheets or plates together, is of extremely ancient date. The principle must have been obvious to the first workers in iron, and being really susceptible of very little improvement, the art, if such it can be termed, has been handed down from generation to generation without alteration. Almost the only difference between the boiler seam of a century ago, and that of the present day, is found in the use of the "snap," for finishing the rivet point. We are not aware of the existence of any very old structures of plate iron which have the rivets so finished. "Snapping" a rivet, only adds to the finish of a joint, but in no way conduces to its strength, and can scarcely be considered in the light of a substantial improvement.

Until a comparatively recent date, the belief obtained with most engineers that a rivetted joint, if the work were properly executed, was superior in strength to the plate itself—an assumed fact which they endeavoured to account for, on the ground that the contraction of the rivet during the process of cooling, bound the two surfaces in contact so closely together, that the friction between them prevented the exertion of much shearing force on the rivets, and compensated for the weakening occasioned by punching the necessary holes near the edges of the plates. The fallacy of these arguments was often demonstrated by the failure of rivetted joints while the plates remained intact. Nevertheless, the advocates of the theory held out strongly in support of these views, until Mr. Fairbairn conducted a very valuable series of experiments, which resulted in proving, that the strength of the plate being taken as 100, that of a double-rivetted joint will be 70, and that of a single-rivetted joint 56. This, be it remembered, with first-rate workmanship. American engineers have tested the real value to be attached to the friction between two surfaces rivetted together as in ordinary seams, with the exception that the holes were made oval in the direction of the strain for the purpose of experiment. A very considerable force was required to cause the plates to slip on each other, but this fact did not affect the results in the least. They amply confirmed those given by Mr. Fairbairn. 56 per cent. of the whole strength of the plates which form a steam boiler is certainly not much to realize with the best workmanship; but as many of our boilers and ships are put together, even this per-centage must be regarded as too high. There are difficulties involved by the nature of the process which the best mechanic can only combat, seldom or never overcome. However accurately two plates may correspond before the holes are punched, that process inevitably distorts them, and occasions a bad fit when subsequently put together. The hammering and bending at the edges entailed, is invariably injurious to cold plates. Again, the best possible workmen, with the best machinery, find it out of the question to make all the holes in a long seam correspond. The constant use of the drift is a result certain to follow; and when plates are of inferior quality or very thin, and the holes near the edge, cracks are frequently established from one to the other. The judicious use of the caulking chisel easily conceals the defect, which is none the less serious because it is invisible. Even the drift often fails, however, to secure the entrance of the proper rivet, and one made of lead is the substitute. The best rivets, too, seldom completely fill the holes they occupy. They are seldom or never truly at right angles to the plates, and are often exposed to an enormous strain in drawing plates together where they are badly fitted. We have seen from this cause, the heads fly off half a score of "Best Best" rivets at once in rolling a new boiler from one side of a shed to the other. When we take all these circumstances into consideration, we believe that 46 per cent. of the strength of the plates, will pretty accurately represent that of the seams of a very large proportion of our boilers if single-rivetted, as most of them are.

Impressed with the evils of such a system, Mr. Fairbairn introduced the use of iron plates rolled with thickened edges, to compensate for the loss of strength entailed by the holes. The objection to their employment he sums up in a few words:—"At the commencement of the trade in iron shipbuilding I patented an arrangement for rolling plates with thick edges, and employed plates so prepared to some extent; but the cost of production at that time and some difficulties in their employment prevented their general use." The whole principle, indeed, of rivetting boilers is so erroneous that it is scarcely susceptible of much improvement.

Within the last few years, attempts have been made with more or less success to unite the plates of boilers, ships, &c., by welding, instead of rivetting. The first English patent, apparently, which touches on the subject, was taken out 1825, by a Mr. Whitehouse, for welding tubes "by circumferential pressure without a mandril." The next was by Stratton in 1844, for welding plates to form hollow ribs for ships; which the patentee proposed to effect, by rolling strips of metal concave, with flanges; which strips of metal being placed with their concave sides towards each other, and the flanges being welded together, formed tubular ribs for ships, &c., as proposed. Some of the first locomotives built by Bury had welded joints. A patent was obtained by William Bertram in 1854, which seems to be the first proposing the application of a gas flame urged by a blast, to the heating of plates to be welded. The patentee scarfed the edges of the plates, placed them together, and directed two pure gas flames, obtained by the combustion of coa or coke in suitable furnaces, on either side of them until raised to a welding heat, when they might be united by pressure or hammering. William Morgan patented nearly the same process in January, 1856. Russell, in 1859, proposed to employ a framing with two arms; the lower one supporting a convex tool or anvil, which going inside of, aided in sustaining the boiler being welded, its weight chiefly resting on rollers, which were fixed near the ground. The upper arm carried another tool or hammer with a convex face, which was traversed up and down in vertical slides, on much the same principle as that involved in Ryder's forging machine. Two portable gas furnaces were provided, one within, the other outside the boiler, to raise the plates to the welding point. The whole apparatus appears to have been simple and well-contrived; but from some cause it has not come into general use. Alleyne, in December, 1859, patented an invention for welding boiler plates, by the intervention of a "glut," which consisted of a bar of iron, with a cross section resembling I. The edges of the plates to be welded were inserted into the grooves, which aided in retaining them in their place. The whole was then exposed to suitable gas jets, and raised to a welding heat and united by the pressure of rollers or by the hammer. The "glut" was intended to prevent the oxidation of the plates; a needless precaution, as flame is incapable of oxidating a metal surface. Still there are certain matters of practical convenience, which incline us to the belief that the principle involved in this patent may be occasionally employed with advantage, particularly in welding transverse seams in circular boiler shells.

There can be no doubt that there are many difficulties to be overcome, before welding will be received by the practical boiler-maker as an efficient substitute for the rivet. Plates heat unequally, buckle, blister, and frequently become exposed, while hot, to the air for a space of time sufficient to provide a coat of oxide fatal to the future joint. Such obstacles are too important to be passed lightly over; still less should they be regarded as insurmountable. They embrace nothing more than the usual troubles which attend on the introduction of any novel process. To combat them properly certainly requires patience, energy, some talent for invention, and a certain amount of capital, for all of which it is reasonable to ex-

pect a satisfactory return when the process has been perfected by their expenditure. The difficulties involved are, after all, by no means serious. It is easy enough to raise a square foot or so of thin boiler plate to a welding heat; that once attained, simple pressure alone is necessary to ensure a joint equal, if not superior, in strength to the plate. By the adoption of this principle, we could reduce the thickness of our boiler plates by one-half, rendering them lighter, and more easily handled and worked in every way. The expense incurred should not be higher than that of the rivetted joint. The extra trouble of fitting and scarfing would not equal that of punching; and the fuel consumed in rivet-making and heating would nearly suffice for welding. Engineers must remember that the principle is neither new nor untried; that it has been, and is worked practically, and only requires to be introduced more generally—not originated. Thus, the boilers of Shand and Mason's fire-engines are welded. Beyer and Peacock weld many of their locomotive boilers. The art is nearly as old as the steam-engine; and although it has lain dormant for years, we trust that it will ere long become almost universal in its application to steam boilers of every kind. There are, it is true, certain situations to which it is inapplicable. Different joints may be found in almost every boiler, save the simple cylinder, which can be joined better by rivets than by any other expedients; but these are exceptional, and, as a general rule, we may consider that no difficulties stand in the way, save those which are easily overcome by moderation in our aim, and such an amount of skill and energy as is commonly to be met with among our working engineers.

THE ENGLISH AND FRENCH NAVIES.*

The wise wish to "see ourselves as others see us," is sometimes realized by the perusal of the writings of an able contemporary foreigner; and a comparison instituted between the naval forces of France and Great Britain by a Frenchman of honesty and ability, could scarcely be without interest, even if it did not free us "frae mony a blunder and foolish notion." M. Xavier Raymond's work—dedicated *aux Marins de la France*—is no production of a monomaniac like, for instance, the Marquis de Boissy. While feeling warmly as a Frenchman, and justly proud of the achievements of the French Navy during the last half-century, he candidly does justice to the immense latent resources of England, and principally blames for our naval shortcomings the British Admiralty, that "inert indolent body, with inordinate powers of consumption, and with proportionately small powers of production; condemned by its very constitution to improvidence and surprises, and possessing very little faculty to keep its affairs in order."

According to the preface the main objects of this work are, in the first place, to refute England's claims to a limitation of the naval forces of other nations; to show how France has developed her Navy since 1815, and that England has been obliged to follow every step if she did not wish to be left behind in the race; to examine into the causes of our recriminations against the French Navy; to warn France against too great a confidence that would lead her to underrate England's naval power; and, lastly, to point out a fatal error in the means adopted in recruiting the naval war service of the French. Without further entering into the political side of the question, we may state that M. Raymond takes a reasonable view of the naval preponderance of England; he acknowledges that it is our duty to perpetuate that preponderance, but he refuses to receive it as a part of international law to be recognized by other Powers; we must maintain it by our own practical exertions.

M. X. Raymond shows that every important advance in maritime construction since 1815 has had its origin in France; and England, the then Mistress of the Seas, has had France for her *institutrice* in the principal maritime improvements made from that date up to the present time. "The improvements in the build of sailing ships, and in the details—such as Barbotin's capstan—are all of French origin. When the application of the propeller allowed of building real steam war-ships, the first model was a French ship, the 'Napoleon.' The iron-clad batteries proposed by the Emperor of the French having shown at Kinburn the value of iron armour for defence, France thereupon built the 'Gloire,' the first type of an iron-cased fighting ship, which, in the words of M. Dupuy de Lôme, would be 'like a lion among a flock of sheep, when encountering a whole fleet of wooden ships.' In the means of attack, France, after furnishing Paixhan's guns against wooden walls, was the first to actually employ the rifled gun as an ordinary weapon; and the 'Gloire' herself is now furnished with 36 rifled *breech*-loading guns. The only improvements of English origin are Cunningham's system of reefing sails, and Clifford's plan for boats." This review, truthful as it is in the main, is certainly not gratifying to our national pride.

The third essay is devoted to the application of the screw as a marine propeller, and to a claim for France of the invention of the marine engine itself and of its screw. The history of invention has yet to be written; but had we space we could show that M. Raymond herein annexes rather too much for his countrymen. Floating batteries and iron-clads are next treated on by the writer, and after numerically giving the dimensions and armament of the "Gloire," and the "Warrior" respectively, he institutes a comparison between the two vessels, to the disadvantage of the latter. The "Warrior" "is a horse too big for its stables," from our inadequate dock accommodation for such a large vessel; she can only carry coal for six days' consumption, against the eight days' of the "Gloire; only two-thirds of the vessel and 13 of the guns are protected with armour; the well for throwing the screw in and out of gear, "is a solution of continuity of the vertebral column of the vessel;" the use of sails and cordages is a source of weakness to a steam-vessel with a propeller, as a piece of rope accidentally driven in by the propeller may completely disable the latter. This was shown in the case of the French vessel, the "Isly," which had to be docked in order to remove a piece of rope entangled with the screw. M. Raymond also points to the inferior performances in practice of the "Warrior," as compared with the "Gloire." With regard to the 68-pounders composing the armament of the "Warrior," he states that careful experiments conducted with these guns at Vincennes have shown that they could not penetrate plates 12 centimetres (4¾ in.) thick at a distance of 300 metres—an achievement accomplished by the ordinary French rifled guns at a range of 1,000 metres. The opinions of several English engineers are quoted as an affirmation that our iron is much inferior to that produced on the Continent; and it is stated that iron plates from the same works as those of the "Warrior," when tried against similar plates to those furnished by Petin and Gaudet for the "Gloire," proved themselves greatly inferior to the latter in their powers of resistance.

In an examination of the Armstrong gun, as compared with other rifled artillery, he states that the French officers who had an opportunity of witnessing its performances in China give very unfavourable accounts of this kind of ordnance; while our author recalls to our memory that the report of Major Hay—specially sent to China to examine into the practical working of Armstrong's gun in front of the enemy—is not yet published, although the Government has been often called upon to do so—a very significant fact. He justly characterizes Armstrong's gun as being "an effort to transform into a cannon the *old-fashioned rifle with a forced ball*." M. Raymond gives the preference to Whitworth's gun, which he asserts to be a mere modification of the rifled gun introduced into the French service by Colonel Treuille de Beaulieu, who began experiments with this kind of improved ordnance so long ago as the year 1842. It is the old story of necessity forcing a recourse to superior organization and science for an amelioration of natural deficiencies. Just as French cooks make up for the bad meat by good cookery, Frenchwomen their general lack of beauty by careful dressing, French soldiers their deficient *physique* by thorough training, so does the French Navy make up its want of ingrained maritime genius by a thoroughly scientific organization.

M. Raymond does not agree with the shallow assertion that steam power has re-established an equality on the seas. On the contrary, the introduction of steam-vessels is to the advantage of the maritime preponderance of England. Could any Power of the second order—for instance, Holland—again offer a naval combat such as that of Camperdown? The Dutch do not possess a single steam line-of-battle ship nor a single iron-clad frigate, nor could they afford the expense of ships able to meet the present naval armaments of England in the same way as those of the brave and unfortunate Admiral de Winter. Again, although the picked seamen, the topmen of old, are no longer required on the present battle ships "as bare as pontoons," the engineers, the firemen, coalers, &c., will want quite as much strength, address, courage, and experience, and especially knowledge, as the best able seamen of former times.

It requires as much strength to live in the "hell" of the furnaces, and as much agility to pass amidst the working parts of the engine in motion, as to reef the sails in a storm; while more intelligence is demanded to work and repair the engines. In the same way, the fatigue of taking in the coal for the engine exceeds anything required from the men in the old sailing vessels. Serving the new guns—firing two shots a minute to the two shots every five minutes of the old ordnance—is also more laborious, and demands more physical power from the sailor than under the old system. The weight of the projectile is doubled; the charge of powder is increased; the guns themselves are heavier, and have to be fired at an enemy in continual motion—moving at a speed of perhaps 14 miles an hour. The vessels of the fleet itself will no longer fight in order of battle at a cable's length apart, but can almost touch each other and manœuvre like a line of infantry—shoulder to shoulder. Blockades will no longer be raised at the slightest symptom of bad weather, but will be

* *Les Marines de la France et de l'Angleterre.* Par Xavier Raymond. Paris and London. 1863. (The greater part of Mr. Raymond's book appeared last year in four numbers of our highly-esteemed contemporary, *La Revue des Deux Mondes.* See the numbers for the 1st and 15th of June, and the 1st and 15th of July, 1862.)

continually maintained without losing sight of the coast. It appears that the French naval administration has arranged a regular system of naval tactics; founded upon the present possibility of manœuvring ships like so many individual soldiers or regiments. We thus see that that the facilities given by steam have increased the demands upon the power of the sailor, and this is so far favourable to our country from the undoubtedly superior *physique* of our own sailors.

The maritime power of any nation is a product of three factors:—money; fully developed manufactures; and a population of seamen—itself a result in direct proportion to the commercial navy of each people. At sea, still less than elsewhere, could individual energy and enthusiasm supply the want of money. At the beginning of the century, the English—by dividing the total expense of a fleet by the number of its guns—reckoned that each gun came to £1,000. This estimate rose to £5,000 and £6,000 in the steam line-of-battle ships; and it is now more than £10,000 for each broadside gun in the iron-clad frigate "Warrior." The "Warrior" has cost £400,000, and she is only partially protected by 4½ in. plates; the "Minotaur" with her 5½ in. plates will represent £500,000 of the public money—and similar plates have been shattered by projectiles. The cost of ships with 8 in. or 10 in. plates will be still higher, and it will thus be "impossible to be a maritime power without the disposal of a heavy budget, and a power of obtaining heavy sums at any given moment." A command over capital is not, however, sufficient; the help of manufactures in a high state of development is absolutely required. "The movement towards an increasing use of iron for all kinds of shipbuilding, is continually narrowing the relations between naval warfare and industry—between what was formerly a world of itself and what is now the ordinary state of things; between the powers of warfare and the powers of production of the workshops cultivating by preference the arts of peace." Nearly all these workshops can become engines of war of incalculable power; "like the industrious bee armed with a sting for the defence of her honey," the workers can turn round with dreadful energy on the disturber of their peaceful labour. The Russians experienced this in 1855, and were, nevertheless, only at the outset of what was being prepared against them, when they saw themselves forced to yield to the demands of their adversaries. Notwithstanding the number and valour of their troops fighting on the national soil, they were crushed by the immensity of warlike materials belched forth with such speed by the far-off workshops of France and England. The same thing is going on in the United States. Not less brave than their enemies, and, perhaps, having more military spirit, and fighting at the same time for their homes—theConfederates are obliged to recoil before the gunboats of the Federals, the superiority of their armaments, and before the results of the blockade depriving the Southern States of the means of renewing their materials of warfare. The Southerners are thus learning by experience that a country may be rich, and yet find itself at a disadvantage in war without the manufactures for arming, equipping, clothing, and feeding an army of soldiers." Should a great war now break out, its principal characteristics would consist in the inexhaustible fecundity with which the manufacturing powers of each state could produce the war materials of the belligerents; and the might and suddenness of the blows given at the outset by the aid of industrial agencies. The largest anchors, engines, and iron-plates are manufactured in the private establishments of France—and private firms play a still larger part in England. The foundries turning out the large and ponderous shafts for 11,000-horse power engines would make light work of guns and anchors of the largest size.

The most brilliant essay in the book is that in which M. Raymond shows up the British Admiralty—"that gossiping old woman, two hundred years behind the pettiest engine-maker of the country." The inferiority of British fleets in the ships composing them; in their interior organization; in the performance of manœuvres; in the disgraceful mutinies of late years; in retrograde character of the construction of the vessels; in the dangerous advances given to France in the adaption of steam and armour to naval warfare; are all owing to that "least rationally constituted administrative body of any other country—one of the most singular institutions in the world, and the most fatally condemned to consume immense resources in the production of comparatively slight results." The only cleverness shown by the Admiralty consists in its usual dodge, whenever the French naval administration is in advance through the adoption of any new invention. "Instead of acknowledging its faults, the Board accuses France of projects of invasion and conspiracy; and having sufficiently disturbed the minds of the nation, the Admiraly then obtains the millions required to make up for its past blunders." We have not sufficient space to at present develop M. Raymond's bill of indictment against this plague-spot of our administration; it may be sufficient to say that all patriotic Englishmen will cordially subscribe to his statements. He does not omit showing up a great mistake in the naval adminstration of his own country. According to the French law of the *inscription maritime*, every Frenchman in the least way connected by his daily occupation with a seafaring life, is every instant liable—from the age of 18 to 50—to be pressed as a seaman and to be sent to the Antipodes in any of the Imperial vessels. This law has undoubtedly acted like an incubus, for the last two hundred years, on the development of the French Navy. According to the late statements in the French Senate of Admiral Romain-Desfossés, France could only reckon upon 62,000 able seamen in all, against the 80,000 kept by England in times of peace under her war-flag, and the 230,000 English sailors employed in long sea voyages and the coasting trade. By applying to the whole seafaring population the laws of the French "Inscription Maratime," counting the small coasting trade, fishermen, boatmen, and workmen in the dockyards, England could reckon on 700,000 to 800,000 men.

This book is, indeed, well worthy to be read by all seamen. Although not a seaman himself, M. Raymond has had much to do with naval matters. He was attached by M. Guizot to the Mission of M. de Lagrénée to China, about twenty years ago; he has made many sea voyages; and he informs us that he has studied for the last twenty-five years the naval question, and has had much personal intercourse with naval men.

IRON SHIPS AND IRON-PLATING.

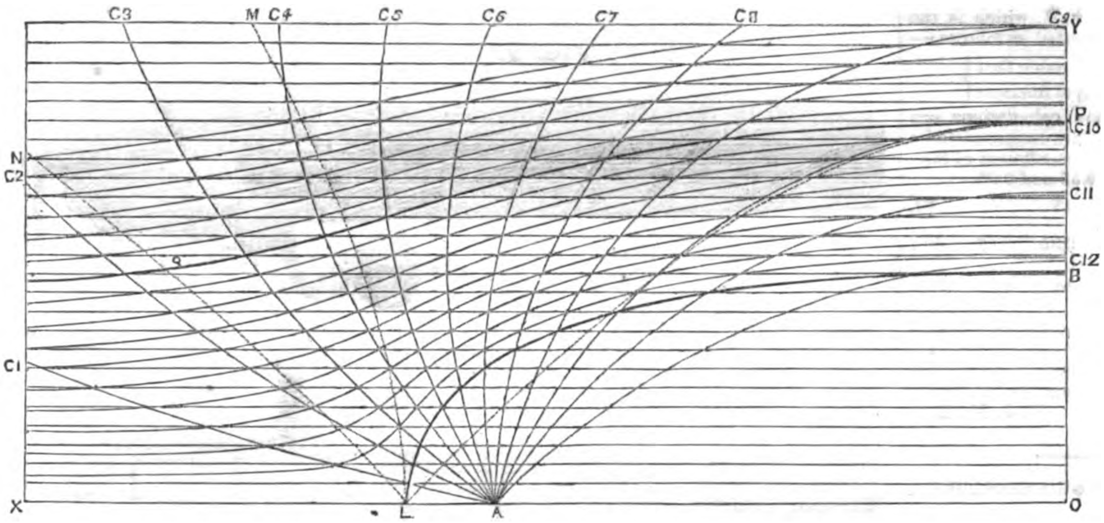
(From the *Times*, August 22, 1863.)

The following extract from the Mechanics' Magazine of Satuday, June 5, 1824, shows how completely the idea of what are considered modern discoveries was anticipated by scientific writers forty years ago. It would seem as if forty years represented the necessary time between the conception and the execution of an idea:—

"Since the discovery by Mr. Perkins of so vast a destructive power as his steam artillery, it becomes of more importance than ever that nations should learn to make their ships as shot and shell proof as possible. On this subject there is, in Ferusac's *Bulletin des Sciences Technologiques*, a memorial by M. de Montgery, a captain in the French navy, which is well worthy of attention, and from which chiefly we shall extract the materials of the present notice. The authors object is to recommend the universal adoption of iron instead of wood in the structure of ships. A multiplicity of objects formerly composed of wood are now formed of iron—bridges, arches, aqueducts, public highways, and other objects not so colossal, but very important in their application to maritime affairs, such as wrought-iron tanks and hollow cylinders for masts and yards, and chains in lieu of hempen cables and cordage. But why up to this time have there been so few vessels constructed entirely of iron? Will not mankind at some future period wonder how enlightened nations could have thought of building objects so stupendous and so expensive with so fragile and perishable a substance as wood, while they possessed a material to substitute for it so solid and durable as iron? The ordinary term of duration of wooden ships is twenty years, and during that period they must be hove down and thoroughly repaired three or four times. To the duration of an iron ship, on the contrary, it would be difficult to assign any period. Vessels of this description have no need of caulking, or copper bottoming. Little subject to leaks there is less fear of their running ashore; and still less are they subject to the casualty of fire. The first cost of them might be greater (that we doubt), but from their far greater durability, and standing so little in need of repairs, the saving in the end would be immense. It deserves further to be considered that large timber is becoming every day more and more scarce, while from the increased dimensions of new ships more wood is required in shipbuilding; of iron, on the contrary, the stores are inexhaustible. It may be said that the adoption of iron would serve to uncraft or disqualify a numerous body of men (the shipwrights), and throw them for a time out of employment. A temporary inconvenience to a few ought not, however, to be opposed to a great general good, considering, moreover, how much the country at large would gain by the increased activity which this new demand for iron would give to our mines commerce, and agriculture.

"M. Montgery contends that while we have vessels of war constructed of wood they should at least be plated with iron, and it will be seen from the following passage that he had distinctly anticipated such an application of projectile force as that discovered by Mr. Perkins:—'For more than 350 years it has been in agitation to throw shells from mortars horizontally, instead of elevating them according to the general practice. The adoption of howitzers in the field of battle, independently of a great number of special experiments, has at length proved beyond doubt the importance of this mode of firing, which it has also been proposed to adopt on board of ships and on marine batteries.' Long before any one had thought of substituting metal for wood in the construction of large vessels, plates of iron or brass had been used for covering ships of war and battering-rams. The celebrated galley built by Archytas and Archimedes for Hiero, tyrant of Syracuse, was cased in this way. Philo, of Byzantium, afterwards proposed using battering-machines made entirely of metal; but Father Mersenne appears to have been the first who thought of adopting them for ships. M. Montgery says that to render the sides of a vessel shot and shell proof they should have a plating of iron about 6 in. thick—that is, a series of sheets of iron, with blocks of cast-iron between. He conceives that the block would only be necessary in the parts exposed to the fire of the enemy, and that there would be no occasion for them towards the keel of the vessel."

PLANE WATER LINES.



ABSTRACT OF AN INVESTIGATION ON PLANE WATER-LINES.*

By W. J. Macquorn Rankine, C.E., LL.D., F.R.SS.L. & E., &c.

1. This Paper contains an abstract of a mathematical investigation which has been communicated in detail to the Royal Society. By the term "plane water-line" is meant, one of those curves which a particle of a liquid describes in flowing past a solid body, when such flow takes place in plane layers. Such curves are suitable for the water-lines of a ship; for during the motion of a well-formed ship, the vertical displacements of the particles of water are small, compared with the dimensions of the ship; so that the assumption that the flow takes place in plane layers, though not absolutely true, is sufficiently near the truth for practical purposes.

2. The author refers to the researches of Professor Stokes (Camb. Trans., 1842), "On the Steady Motion of an Incompressible Fluid," and of Professor William Thomson (made in 1858, but not yet published), as containing the demonstration of the general principles of the flow of a liquid past a solid body.

3. Every figure of a solid past which a liquid is capable of flowing smoothly, generates an endless series of water-lines, which become sharper in their forms as they are more distant from the primitive water-line of the solid. The only exact water-lines whose forms have hitherto been completely investigated, are those generated by the cylinder, in two dimensions, and by the sphere, in three dimensions. In addition to what is already known of those lines, the author points out, that when a cylinder moves through still water, the orbit of each particle of water is one loop of an elastic curve.

4. The profile of waves have been used with success in practice as water-lines for ships, first by Mr. Scott Russell (for the explanation of whose system the author refers to the Transactions of the Institution of Naval Architects for 1860-1-2), and afterwards by others. As to the frictional resistance of vessels having such lines, the author refers to his own Papers; one read to the British Association in 1861, and printed in various engineering journals, and another read to the Royal Society in 1862, and printed in the Philosophical Transactions.

5. The author proceeds to investigate and explain the properties of a class of water-lines, comprising an endless variety of forms and proportions. In each series of such lines the primitive water-line is a particular sort of oval, characterized by this property—that the ordinate at any point of the oval is proportional to the angle between two lines drawn from that point to two foci. (In the figure, LB represents a quadrant of such an oval; O being its centre, and A one of the foci. The other focus is at an equal distance to the other side of the centre.) Ovals of this class differ from ellipses, in being considerably fuller at the ends, and flatter at the sides.

6. The length of the oval may bear any proportion to its breadth, from equality (when the oval becomes a circle) to infinity. (In the figure, the length OL is to the breadth OB, nearly as 17 : 6).

7. Each oval generates an endless series of water-lines, which become sharper in figure as they are farther from the oval. In each of those derived lines, the excess of the ordinate at a given point above a certain minimum value, is proportional to the angle between a pair of lines drawn from that point to the two foci.

8. There is thus an endless series of ovals, each generating an endless series of water-lines; and amongst those figures, a continuous or "fair" curve can always be found, combining any proportion of length to breadth from equality to infinity, with any degree of fulness or fineness of entrance, from absolute bluffness to a knife-edge.

9. The lines thus obtained present striking likenesses to those at which naval architects have arrived through practical experience; and every successful model in existing vessels can be closely imitated by means of them, from a Dutch galliot to a racing-boat.

10. Any series of water-lines, including the primitive oval, are easily and quickly constructed with the ruler and compasses, as follows:—Parallel to the longitudinal axis OX, draw a series of straight lines at equal distances apart. Through the foci, draw a series of circular arcs AC^2, AC^2, &c., so as to contain a series of angles found by dividing those distances by

$$\frac{OL^2 - OA^2}{QOA}.$$

Each of those circular arcs indicates the direction of motion, in still water, of each of the particles that it traverses. Then through the angles of the network formed by the straight lines and circular arcs, draw a series of curves; these will be the required water-lines.

The centre of curvature of the oval at L is the focus A.

11. The following curves, traversing certain important points in the water-lines, are exactly similar for all water-lines of this class, and are easily and quickly constructed with the compasses.

LM is a hyperbola, having a pair of asymptotes crossing the axes at O at angles of 45 deg. It traverses all the points at which the motion of the particles, in still water, is at right angles to the water-lines.

LQN, and LP, are the two branches of a curve of the fourth order, having a pair of asymptotes which traverse O, making angles of 30 deg. with OX. A straight line joining L and P makes an angle of 30 deg. with LO. The two branches cross the axis OX as L, making angles of 45 deg. The branch LQN traverses a series of points at each of which the velocity of gliding of the particles of water along the water-line is less than at any other point on the same water-line. The branch LP traverses a series of points, at each of which the velocity of gliding is greater than at any other point on the same water-line.

12. The axis OY, from B to P, traverses a series of points of minimum velocity of gliding: from P onwards, it traverses a series of points of maximum velocity of gliding.

13. Every water-line, complete from bow to stern, which passes within the point P, has three points of minimum and two of maximum velocity of gliding; while every water-line which passes through or beyond P, has only two points of minimum and one of maximum velocity of gliding. Hence the latter class of lines cause less commotion in the water than the former.

14. On the water-line PQ, which traverses the point P itself, the velocity of gliding changes more gradually than on any other water-line having the same proportion of length to breadth. Water-lines presenting this character can be constructed, with any proportion of length to breadth, from $\sqrt{3}$ (which gives an oval through L and P) to infinity. The finer of those lines are found to be nearly approximated to by wave-lines; but are less hollow at the bow than wave-lines are.

15. The author shows how horizontal water-lines at the bow, drawn according to this system, may be combined with vertical plane lines of motion for the water at the stern, if desired by the naval architect.

16. In this, as in every system of water-lines, a certain relation (according to a principle first pointed out by Mr. Scott Russell) must be preserved between the form and dimensions of the bow and the maximum speed of the ship, in order that the appreciable resistance may be wholly frictional, and proportional to the square of the velocity (as the experimental researches of Mr. J. R. Napier and the author have shown it to be in well-formed ships), and may not be augmented by terms increasing as the fourth and higher powers of the velocity, through the action of vertical disturbances of the water.

ABSTRACT ON THE PROPORTIONS OF SHIPS OF LEAST SKIN-RESISTANCE FOR A GIVEN SPEED AND DISPLACEMENT.*

By W. J. Macquorn Rankine.

The author referred to a previous Paper, which he had read to the British Association in 1861, and in which he had stated the results of a theoretical investigation of the "skin-resistance" of ships, and verified those results by a comparison with those of experiments. In the course of that Paper he had stated that the theory gives, for the proportion of length to breadth which produces least skin-resistance with a given displacement of speed, that of *seven* to *one* nearly.

This is the case *when the figures and proportions of the cross-sections are given*, so that the draught of water bears a fixed proportion to the breadth. But *when the draught of water has a fixed absolute value*, the theory gives a somewhat different result; for the proportion of length to breadth which produces the least skin-resistance is found to increase as the draught of water becomes shallower.

* Read to the British Association in August, 1863.

* Read to the British Association, August, 1863.

In the following table of examples, L denotes the length, B the extreme breadth, H the draught of water, and the ratio $\sqrt{LB} \div H$, which is the argument of the table, is computed as follows:—

$$\frac{\sqrt{LB}}{H} = \sqrt{\left\{\frac{\text{Displacement in cubic feet}}{H^3 \times \text{co-efficient of fineness}}\right\}}.$$

In the vessels to which these calculations are applicable, the cross-sections are supposed to be nearly rectangular, and the "co-efficient of fineness" is in general between 0.55 and 0.65.

xample No.	I.	II.	III.	IV.	V.	VI.
$\frac{\sqrt{LB}}{H}$ =	5·2	9·9	15·6	22·5	30·7	40·2
$\frac{L}{B}$ =	7	8	9	10	11	12
$\frac{B}{H}$ =	2	3·5	5·2	7·1	9·3	11

The general agreement of these results with successful practice in shipbuilding is obvious.

W. J. M. R.

Glasgow, August 17, 1863.

STORM'S BREECH-LOADING ORDNANCE.

FIG. 2.

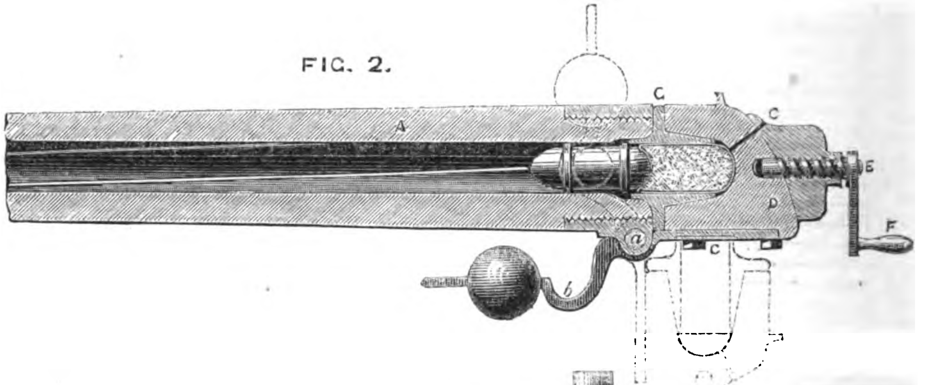


FIG. 1.

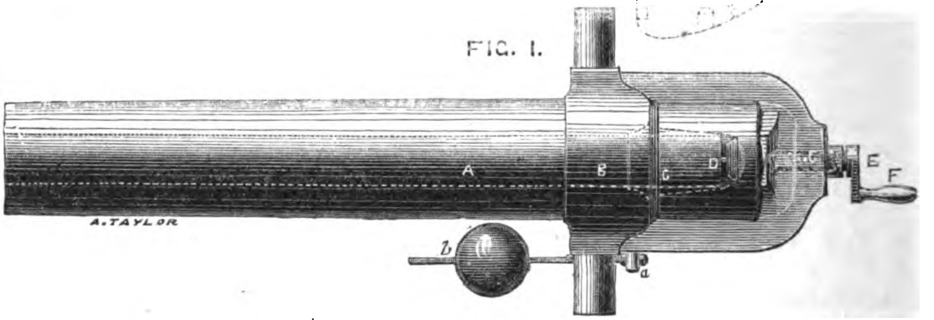

As a company is being formed to introduce this system of breech-loading, we illustrate it this week. The invention is patented by Mr. W. M. Storm, of New York.

It relates, firstly, to improvements in breech-loading cannon, whereby they will be effectually secured against the escape of lateral fire during a discharge, and the operation of loading the gun will be greatly facilitated.

The main object of this part of the invention is the application of the gas check or valve, which consists of a loose tubular lining which fits into the barrel of the weapon and covers the junction between the barrel proper and the breech piece, and being capable of an endway movement, by reason of the expansive force of the ignited powder, will completely seal the joint between the breech and barrel.

In applying the gas check or valve to breech-loading canon, the patentee adopts the arrangement shown in the accompanying drawings, where fig. 1 is a plan view of the improved cannon; fig. 2 is a longitudinal section of the same.

A is a barrel of the cannon, provided at its inner or rear end with a screw thread, which takes into a hollow screw tapped in the breech frame B. This hollow screw or ring carries the trunnions, and forms the forward end of the breech frame. On the under side of the trunnion ring two lugs are formed to receive a transverse axle *a*, which passes through a similar lug formed on a hinge piece C, attached to the moveable breech D. Keyed to this axle is a weighted lever *b*, which serves to counterbalance the breech, and thereby facilitates the working of the gun. The rear end of the breech frame B is tapped to receive a quick screw E, which is operated by a winch handle F, and enters a hole bored in the rear end of the breech, for the purpose of securing it in position when the cannon has been charged. A recess is made in the breech chamber to receive the gas check or valve G, the front end of which projects into the barrel. The vent *c* for firing the cannon is carried through the breech frame to give access for priming, so that if by any chance it is attempted to fire the charge before the breech is brought "home" or to its proper position, the vent will be closed by the hole in the breech frame not being in coincidence with that of the breech. To charge the cannon, withdraw the screw bolt E by means of the winch handle F, and let the breech fall into the dotted position of fig. 2, when the valve G will come away with the breech. In the breech chamber, contracted by the insertion of the valve G which forms a lining thereto, the cartridge is placed, and the shot or shell is inserted in the barrel of the cannon through the now open rear end; then, by means of the weighted lever *b*, raise the breech into position, as shown at fig. 2, and secure it there by the screw bolt E. The cannon is then ready for firing. For adjusting the cannon to the proper angle for firing, the elevating screw or analogous device is provided in advance of the trunnions instead of in rear thereof, as heretofore.

It will be understood that the barrel of the cannon may have a smooth bore or be rifled as thought most desirable, and that shots or shells of any suitable construction may be employed therewith. The part of the gas check or valve G, which overlaps the rear end of the barrel, is, by preference, formed with a curved face, the curve being struck from the axis of the supporting hinge.

The principle is not less applicable to rifles or small arms than to guns. As applied to rifles of the regulation pattern, the arrangement of parts is extremely simple and unlikely to get out of order, one so constructed having been discharged 300 times consecutively at the late meeting at Wimbledon, as quickly as it could be loaded, with the most satisfactory results. Further information may be obtained from Mr. F. A. Braendlin, 3, Rood-lane.

TRIAL TRIP OF THE "AURORA."

The trial trip of this fine twin-screw steamer took place on Tuesday last. The "Aurora" is an iron vessel, 165 ft. in length, with a beam of 23 ft., a depth of 13 ft. 6 in., an area of midship section of 150 square ft., and a displacement of 400 tons. Her engines have a collective nominal power of 120-horse, and drive two 3-bladed screws, each independently of the other, 7ft. in diameter, and with a pitch of 14 ft. 6 in. The cylinders have a diameter of 26 in., and a 21 in. stroke. She carries two short masts, rigged for fore and aft canvas. Her draught of water at starting was 7 ft. 3 in. aft, and 5 ft. 3 in. forward.

A large party of gentlemen left town on Tuesday morning by the 10 52 train from Fenchurch-street for Tilbury station pier, alongside which the "Aurora" lay with her steam up. Immediately on the party embarking the screws were set to work in opposite directions, and the vessel slewed round with her head down river and started on her trial at 12 20 p.m., under the charge of Mr. Leigh, Trinity pilot, the wind being strong at S.W., and the tide half-ebb. In running past the measured mile, in the Lower Hope, with the engines not up in their number of revolutions, she was timed and found to go over the ground in 4 min. 8 sec., giving the vessel a speed of 14·516 knots. At 1 30 p.m. the "Aurora" was approaching the Nore-light vessel, the engines averaging 120 revolutions, with 27 lb. of steam and a vacuum of 25 in., and every part working with the greatest possible smoothness. At 1 37 the Nore was passed, the distance from Tilbury, 20 nautical miles, having been done in 1 hour and 17 minutes, an almost unparalleled rate of speed, considering the vessel's horse-power of engine and hull displacement. From the Nore to the Mouse Light the vessel continued her course, the wind still fresh from the same quarter, and the movement of the water which necessarily accompanied it giving the vessel, from her light draught and hold upon the water, sufficient "roll" to detract from the efficient acting of her only just submerged screws. Notwithstanding this disadvantage, however, she ran past the "mile" on the Maplin Sands in 4 min. 10 sec., giving a speed of 14·400 knots, it being now about slack water, and the tide of little moment either way, and accomplished the distance to the Mouse-light at 2h. 5m. 22s., having been 28 min. and 23 sec. from the Nore—8 nautical miles. During the latter part of the run down a small jib had been set to steady the vessel, but no other help was given by the vessel's canvas to her engines in attaining this somewhat extraordinary rate of speed. From the Mouse the "Aurora" was run out between the Maplin and the Barrow, as far as the Swin-light, passing the "James Dixon," a fine screw collier under sail and full steam, with her head in the same direction as the "Aurora's," on the way. On reaching the Swin the vessel's head was brought round and laid homeward, it having been decided not to lengthen the trial by making circles, &c., owing to the high state of the wind, the light condition of the vessel, and the very satisfactory manner in which she had already turned both to port and starboard in answer to her rudder or screws, proving that she possessed the same facilities in that respect as were possessed by the "Flora," "Hebe," and "Kate"—a facility of manœuvring, in fact, which must necessarily be possessed by every vessel built for and fitted with double screws driven by independent engines. Southend was passed at 4h. 15m., and about two miles ahead was seen the "Sea Swallow," one of the fastest paddle steamers on the Thames, plying between London, Southend, and Sheerness, and a hot chase naturally ensued, the "Aurora" eventually passing the clipper at 4h. 40m. in the midst of a heavy squall of wind and rain, and subsequently during the run up to Blackwall passing everything under steam she came across. Gravesend was passed at 5h. 15m., the engines making on the average at the time 127 revolutions, and Blackwall pier, the closing point of the "Aurora's" day's work, being reached in 1h. 7m., the distance being 20 miles. At Blackwall the numerous visitors on board disembarked and returned to town by rail.

HENLEY'S INDIAN TELEGRAPH.

The *Times* states that the shipment of the Indian telegraph cable from Mr. Henley's factory at North Woolwich is now in active operation. The "Marian Moore," carrying 170 miles of the cable, left the Downs a few days ago for Bombay, and is expected to arrive at her destination towards

the end of November. The sailing ships "Assaye" and "Kirkham," moored alongside the works, are now receiving their cargoes of the wire, which is being rapidly coiled in the holds of both ships simultaneously by steam machinery constantly at work. The former vessel will carry about 360 miles, and the latter about 200 miles. The "Assaye" is well known at Woolwich, where she arrived last year in company with the sister ship, the "Punjab," at that time both paddle-wheel steamers. They were removed from Woolwich to the Victoria Docks, and were sold to a Liverpool firm, since which time they have both been ship-rigged and converted into sailing ships. Both are exceedingly fast sailers, and what is termed "clipper ships." Although fitted with powerful engines they performed the voyage under sail, at the rate (it is stated) of upwards of 16 knots per hour, and made the voyage home in 75 days. They are both constructed throughout of teakwood. The "Kirkham" is an iron vessel, paintedwhite. The cable is coiled in largewater-tight tanks, three on board each ship, which will be kept full of water throughout the voyage to Bombay. They are expected to sail from Woolwich the second week in September, and will be fully equipped with all appliances for paying out the cable at sea. The "Tweed" (late the "Punjab") and the "Cospatrick" will follow the two vessels, now alongside, and will take in 350 miles and 200 miles respectively. The latter-named ships are being fitted at Poplar by Messrs. Wigram for the reception of the cable, under the superintendence of Captain Dicey. The "Charente," a screw steamer of about 600 tons, is being fitted by the above-named firm for permanent employment on the line, and will be supplied with all requisites for repairing the cable, should any accident arise hereafter from ships' anchors, or any casualties to which the wire must be subjected by exposure. The "Charente" will take out a small quantity of cable in addition to her coals. She will be commanded by Lieutenant Stiffe, an experienced officer of the Indian Navy, who has recently surveyed the Persian Gulf specially with regard to this important undertaking. The total length of cable taken out for this line will amount to 1,250 miles, and will weigh upwards of 5,000 tons, being an excess of 2,000 tons over that of the Red Sea, Malta, and Alexandria, or the Atlantic. The wire alone of the present cable weighs 1,000 tons. The operations, which are under the direction of Lieutenant-Colonel Stewart, Royal Engineers, are expected to be completed by the month of February next, when it is hoped that London and Calcutta will be in telegraphic communication, by which a correspondence may be conveyed from one hemisphere to the other in the course of a very few hours. Sir Charles Bright and Mr. Latimer Clark, the consulting engineers, superintending the manufacture of the cable, are attended by a competent and effective staff of electricians at Woolwich, who supervise and test the whole of the work as it progresses. The "Gammelholm," a Danish storeship, arrived and moored off Mr. Henley's works at Woolwich on Saturday morning, preparatory to taking in a telegraphic cable for the Danish Government, which will weigh upwards of 15 tons per mile. Twenty-five miles of the electric wire have also been recently despatched from the same factory to Christiana for the Norwegian Government.

MIDLAND BOILER INSPECTION AND ASSURANCE COMPANY.

THE Engineer's report to the members of this Association at their last meeting, held at Wolverhampton, stated "that during the half-year ending June 30 last, particulars were obtained of 371 boilers, with a view to proposal for inspection of assurance, which, with those before reported, made a total of 2,616. Proposals had been accepted during the six months for the inspection of 215, and the assurance of 134, making together 349 boilers. The total number of boilers under inspection up to June 30 was 619, and under assurance 500, making 1,119 boilers under the care of the company. That number had now been increased to 1,184. The boilers were of the following descriptions:—Plain cylindrical (externally fired), 670; furnace boilers, of various shapes, 235; Cornish or others (internally fired), 126; low-pressure balloon, or waggon-shaped, 88; total, 1,119. These boilers were employed as follows:—Colliery engines, for pumping, 95; ditto, for winding, 234; mills and forges, 123; blast furnaces, 171; canals, water, and gasworks, 43; lathe engines, 22; clay mills, 22; saw mills, 7; rope-walks, 4; flour mills, 3; locomotive, 2; stamping, 3; total, 1,119. All boilers had been subjected to the same careful inspection, and whenever opportunity could be given, they had been examined internally and in the flues. There had been made during the half-year 1,986 external, 163 internal, and 337 thorough—in all 2,486 examinations, and both masters and engine tenters had given every facility for those examinations. Fifty-five reports had been sent to owners as to matters requiring attention, and the recommendations had been speedily carried out. Care had been taken to avoid causing needless trouble or expense. The chief points reported on had been as follows:—Alteration of shape from the insufficiency or want of proper stays, or from undue heating, or careless usage, or from injury by accumulation of scurf or blistering of plates. The strength of the shells of boilers was frequently found greatly diminished by inefficient repair, especially from the use of little narrow patches over cracks on the edges of plates, which might effectually prevent leaking for a time, but which leaves the plate little, if any, stronger than it would be with the crack untouched. Many of these patches have been found on a single plate, and they seldom lasted long, as they burnt off because the water could not reach them. Safety valves are very frequently found over-weighted, either from inadvertence or to prevent leaking when the valve requires "scouring." These valves are of little use unless they are so adjusted as to lift freely at a few pounds above the ordinary working pressure, so as to give complete relief before the pressure can rise to an unsafe height. Much danger would be avoided if the practice were more common of having a valve near each engine of sufficient size to let off as much steam as the engine usually takes, and within easy access of the man in charge to open where there is a "stand." Safety valves are also sometimes over-weighted to make an engine that is out of repair do its required work. Attention having been called to this point in reports, has led to engines being worked with considerably less pressure of steam, thereby effecting great economy. Pressure gauges of all kinds are frequently found out of order and indicating falsely; but this is more often from unfair usage than from defect in their principle or construction. All gauges should be as near as possible to the boilers, so as to indicate the pressure at which the steam is "raised," not that at which it is used. A good gauge, kept in perfect repair, frequently applied to each boiler at taps placed for that purpose, and the safety valves adjusted by it, would often be a greater safeguard than gauges left constantly in exposed positions. Glass gauge tubes can seldom be kept in order in ironworks, as they are so much exposed to breakage. Floats are almost universal, many boilers being fitted with two, but they are too frequently found working badly. Scurf is found in almost all boilers in this district, varying in thickness and composition. Scurf is only of consequence on those parts of the boilers exposed to heat; needless injury to plates and rivets is frequently caused by too vigorously chipping to get it off. The plates near the fire cannot be kept too carefully cleaned. Blow pipes would very much mitigate the evils of scurfing if they were more frequently used, especially in plain cylinder boilers, and those with fire under them. Corrosion is seldom met with on the inside of boilers in this district, but it is a most frequent cause of injury on the outside, from the leaking of the steam pipes and fittings. Thinning of plates from this cause has been most frequently reported, both above and beneath the brickwork, and in many cases to a dangerous extent. In all reports attention was called to anything that was observed likely to lead to injury or expense, as well as to anything causing present danger. There have been twenty-one explosions in various parts of the country since the beginning of 1863.

ASSOCIATION FOR THE PREVENTION OF STEAM BOILER EXPLOSIONS.

AT the last monthly meeting of the Executive Committee of this Association, held at the offices, 41, Corporation-street, Manchester, on Tuesday—Mr. W. Fairbairn, C.E., F.R.S., in the chair—Mr. L. E. Fletcher, chief engineer, presented his monthly report, of which the following is an abstract:—"During the past month there have been examined 313 engines and 401 boilers. Of the latter, 6 have been examined specially, 9 internally, 45 thoroughly, and 341 externally, in addition to which two of these boilers have been tested by hydraulic pressure. The following defects have been found in the boilers examined:—Fracture, 5 (1 dangerous); corrosion, 14; safety valves out of order, 7; water gauges ditto, 9 (1 dangerous); pressure gauges ditto, 15; feed apparatus ditto, 2; blow-out apparatus ditto, 27; fusible plugs ditto, 1; furnaces out of shape, 4 (1 dangerous); over-pressure, 3; deficiency of water, 1 (dangerous). Total, 88 (4 dangerous). Boilers without glass water gauges, 3; without blow-out apparatus, 16; without back pressure valves, 25. Nine explosions have occurred during the past month, from which 5 persons have been killed and 3 others injured. Not one of the boilers in question was under the inspection of this Association. A personal examination of three of these has been made subsequently to the explosion, while in the remaining cases this was prevented by distance. In one case the cause of the explosion was simply the dilapidated condition of the boiler; it had repeatedly been found to leak at the back end, both at the last plate at the bottom, as well as at the flat end one, and had, in consequence, been temporarily repaired, from time to time, with bolted patches. Patches, when necessary, should always be rivetted on, no reliance can be placed upon those merely bolted. At the time of the explosion there were three of these patches on the boiler, within 12in. of one another. The surrounding plate at length became so eaten away by continual leakage, that it was reduced in places to one-eighth of an inch in thickness, and in others to that of a sheet of brown paper, from which rupture ensued, underneath the boiler, at the back end, immediately over the mid-feather; the mid-feather, no doubt, accelerating the corrosion, by ponding the water, and holding it in contact with the plate, at the same time that it concealed the full extent of the injury. Competent inspection could not have failed to detect the dangerous condition of the boiler." The report concludes with suggestions as to the best mode of setting boilers.

SUBSTANCES FOR PREVENTING AND REMOVING BOILER INCRUSTATIONS.

THE following is a list of substances which have been used, with more or less success, in preventing and removing the incrustations which are formed by using hard water in boilers:—

Potatoes.—By using about one-fiftieth of potatoes to the weight of water in a boiler, scale will be prevented, but not removed. Their action is mechanical; they coat the calcareous particles in the water, and prevent them from adhering to the metal.

Extract of Tannin.—A mixture has been used of 12 parts chloride of sodium, 2½ parts caustic soda, ¼ extract of oak bark, ⅛ of potashes, for the boilers of stationary and locomotive engines. The principal agent in this appears to be the tannin of the extract of oak bark.

Pieces of Oak Wood, suspended in the boiler and renewed monthly, prevent all deposit, even from waters containing a large quantity of lime. The action depends principally upon the tannic acid.

Ammonia.—The muriate of ammonia softens old incrustations. Its action is chemical; it decomposes the scale. In Holland it has been used with satisfaction in the boilers of locomotives. About 2 ounces placed in a boiler twice per week have kept it clean, without attacking the metal.

Fatty Oils.—It is stated that oils and tallow in a boiler prevent incrustations. A mixture, composed of 3 parts of blacklead and 18 parts tallow, applied hot, in coating the interior of a boiler, has given great satisfaction in preventing scale. It should be applied every few weeks.

Molasses.—About 13 lb. of molasses, fed occasionally into a boiler of 8-horse power, have served to prevent incrustations for six months.

Sawdust.—Mahogany and oak sawdust have been used to prevent and remove scale; but care must be exercised not to allow it to choke up pipes leading to and from the boiler. Catechu contains tannic acid, and has also been used satisfactorily for boilers. A very small amount of free tannic acid will attack the iron; therefore a very limited quantity of these substances should be employed.

Slippery Elm Bark.—This substance has also been used with some success in preventing and removing incrustations.

Soda.—The carbonate of soda has been recommended by Professors Kuhlman and Fresenius, of Germany, and Crace Calvert, of England. It is now employed with satisfaction in the boilers of engines in Manchester.

Tin Salt.—The chloride of tin is equal to the muriate of ammonia; and is similar in its action in preventing scale.

The *Extract of Tobacco* and *Spent Tanners' Bark* have been employed with some degree of satisfaction. The sulphate (not the carbonate) of lime is the chief agent in forming incrustations. By frequent blowing off, incrustations from carbonate of lime in water will be in a great measure prevented.

TANNAHILL'S IMPROVEMENTS IN RIVET-MAKING MACHINERY.

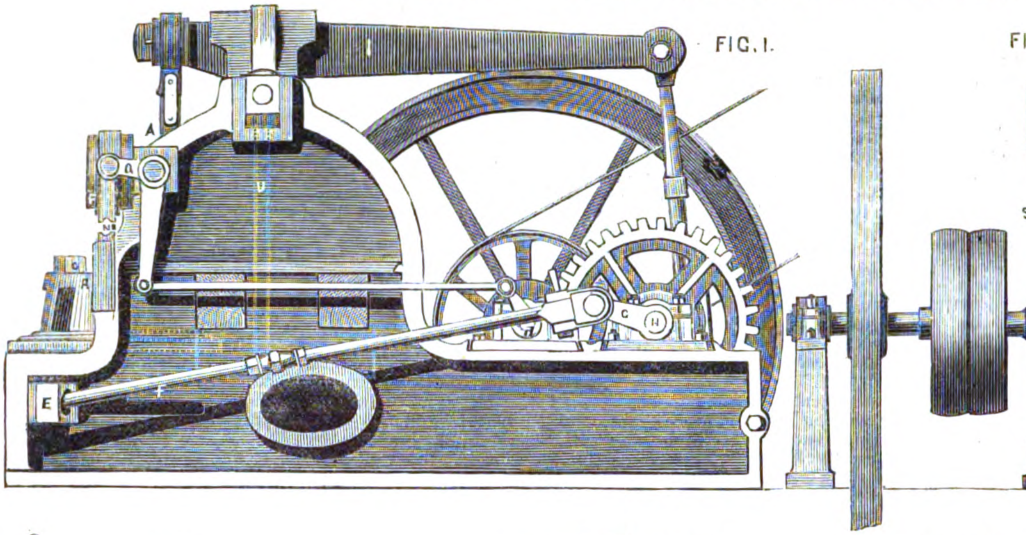

FIG. 1.

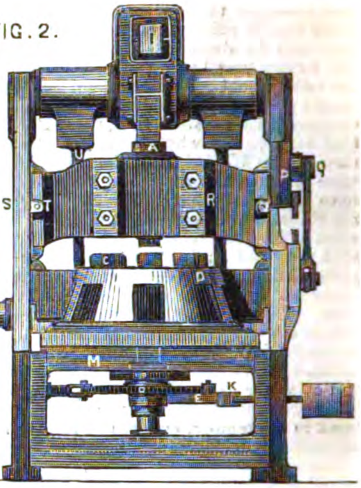

FIG. 2.

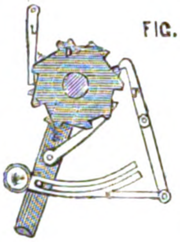

FIG. 4.

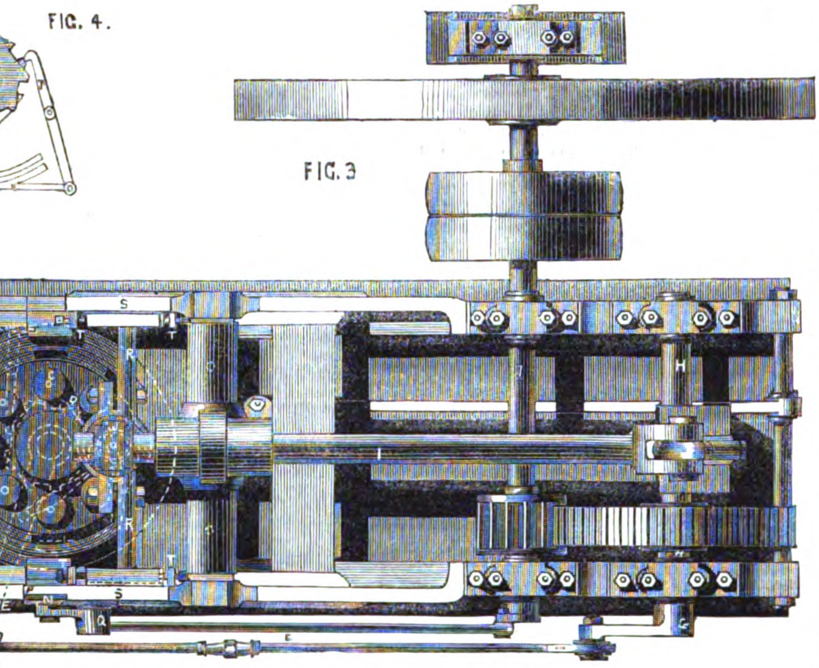

FIG. 3

D. AND J. TANNAHILL'S IMPROVEMENTS IN RIVET-MAKING MACHINERY.

THE following improvements in rivet-making machinery have been patented by Messrs. D. and J. Tannahill, engineers, of Glasgow :—

This invention relates to improvements which are more or less applicable to various kinds of rivet-making machinery.

Fig. 1 is a side elevation, fig. 2 is an end elevation, and fig. 3 is a plan, of a rivet-making machine, embodying some of these improvements. This machine is of the class termed "vertical," from the motion of the ram or shaping-head A being vertical, and in some respects it resembles machines of that class as hitherto constructed. It will therefore be unnecessary to give a very detailed description.

The first novelty relates to the turn-table movement, by which the table or disc B, with the series of dies C, is shifted round between each stroke to bring a fresh die under or in front of the ram or shaping-head A. A difficulty has hitherto been experienced in combining with a simple and easy movement the necessary accuracy of position at each shift; by the present invention, however, this is effected by employing a reversed ratchet with the ordinary ratchet and pawl lever arrangement by which the table or disc B is shifted. The reversed ratchets are indicated by dotted lines at D in fig. 3, and are shown detached in fig. 4. The table B is shifted round step by step by the pawl lever E, actuated by means of a connecting rod F from a crank G on the main shaft H, by which the main lever or beam I is worked. A catch J, indicated by dotted lines in fig. 3, is centered on a stationary stud, and is arranged to engage with the reversed ratchet, being pressed inwards by a spring, and a tooth of the ratchet is brought firmly up against it at each shift by the action of the pawl lever E on the other ratchet. At the commencement of each shift the reverse ratchet-catch J is for a moment drawn out of the way for the point of the next ratchet-tooth to pass it. For this purpose the catch J is fitted with a slotted link K, which embraces the pawl lever E or a pin on that lever, and just as it completes its backward movement, the pawl lever E draws over the link K, and thereby causes the catch J to be moved outwards. An ordinary spring pawl L, indicated by dotted lines in fig. 3, is provided to prevent the table B from moving backwards. The ratchet wheels D are, by preference, constructed so that the faces of the teeth are cut out of steel, cavities being formed in the original block to receive the steel in the requisite positions. This improved shifting movement may be applied to either a "vertical" or a "horizontal" machine. When the machine is vertical, and the die-table or disc B turns about a vertical axis, the table B is, by preference, made to rest and turn in a circular V-shaped groove, as indicated at M in fig. 2, instead of being formed with an inverted groove to rest on a projecting ridge. The machine is provided as usual with cutters N for cutting the blanks off the rods; but the upper or moveable cutter is, by preference, made to work rectilineally in guides P, being jointed instead of fixed to the lever Q, by which it is actuated. The bridge piece R, in which the ram or shaping-head A is guided, is accurately fitted into its seats in the side frames S, but so as to permit of accurate adjustment at any time by means of set screws T, screwed into lugs provided on opposite sides of it for the purpose. In a similar way the rods U, by which the main lever I is held down to the wooden spring beams, are screwed at their lower ends and fitted with nuts, as indicated by dotted lines in fig. 1, so that they can at any time be accurately adjusted.

LÜTHY'S IMPROVEMENTS IN HYDRAULIC PRESSES.

LETTERS PATENT have just been granted to Robert Lüthy, of Solothurn, in the Republic of Switzerland, and of No. 2, Thavies Inn, in the City of London.

The object of this invention is to economize time and labour in the working of hydraulic presses, and also to reduce their weight so as to render them more portable, and thereby facilitating their conveyance to distant parts.

The improvements are applicable to all hydraulic presses, but more especially to such as are intended for packing cotton, wool, hay, and other like materials, and in which the piston has to perform the greater part of the stroke without meeting with much resistance. In the ordinary presses hitherto used for this purpose, the piston or ram is forced through this first part of its stroke simply by forcing the water or other fluid into the cylinder in the usual manner, namely, by means of pumps or accumulators, and at a considerable outlay of time and labour.

Now, the present improvements relate, firstly, to presses in which the piston or ram has to pass through the whole length of the stroke or lift, and consist in raising or moving the ram through the first or principal part of the stroke by means of a screw or screws, or by rack and pinion motion, or by other suitable mechanism; but the patentee prefers to use one or more smaller hydraulic rams for effecting this object.

The said mechanicism or apparatus may be connected with the press piston or larger ram through the press plate commonly called follower, or it may be made to act upon a rod passing through the bottom of the cylinder, and bearing direct upon the ram. In using a small hydraulic

FIG. 4.

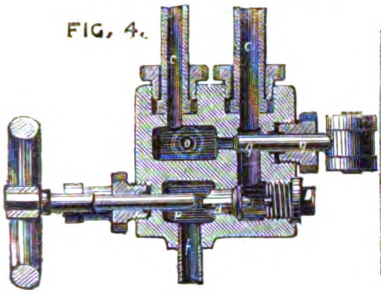

FIG. 1.

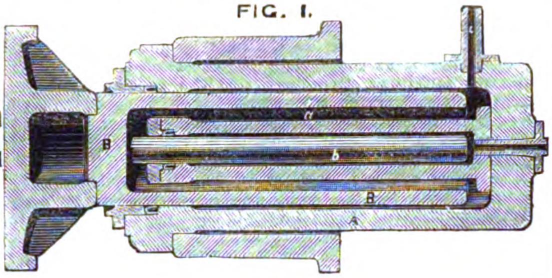

FIG. 2

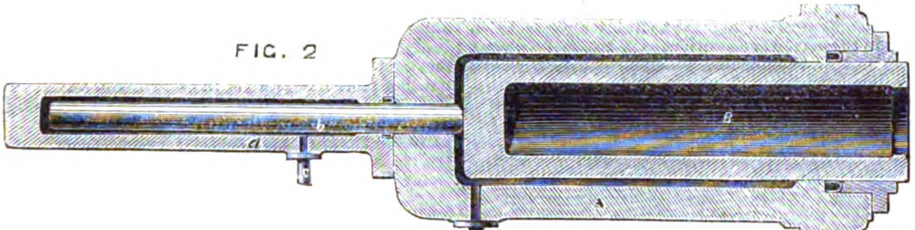

FIG. 3.

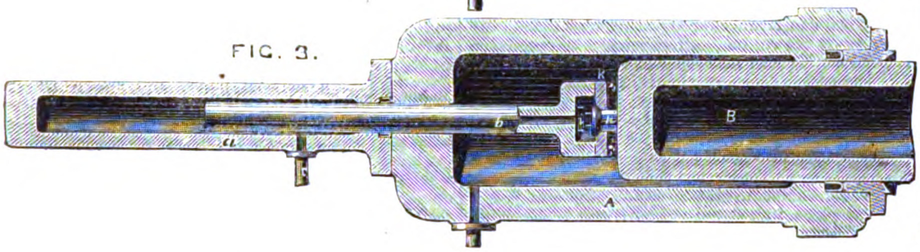

ram and cylinder, however, it is proposed to place the same either outside the large cylinder, the small ram passing through the bottom of the latter, or inside the same, and partly inside the larger ram, so that the small ram acts directly upon the large one, and moves the same through the first part of the stroke, the pressure from the pump or accumulator being at the same time communicated to the fluid in the small cylinder only. During this part of the stroke the large cylinder is filled with water or other fluid supplied from the pump, cistern, or other reservoir. When the resistance of the material under pressure is equal to the pressure of the small ram the supply from the reservoir to the large cylinder is shut off, and the pressure from the pump or accumulator is communicated to the large ram, which will then complete the stroke, and give the final pressure. The small ram may be stationary during this last part of the stroke, and consequently so much shorter, or it may move with the large ram through the whole stroke. The admission of the supply to the large cylinder, and the communication of pressure to the ram may be effected by working cocks or valves by hand; or by the use of a self-acting apparatus connected with all the pipes leading to the cylinders, pumps, or accumulator and supply reservoir. This apparatus consists of suction valve for the supply of the large cylinder during the first part of the stroke of a valve weighted according to the pressure of the pumps or accumulator, which will open and communicate pressure to the large cylinder, when the small ram meets with a resistance equal to its pressure, and of an arrangement for disengaging the cylinders either by common stop-cocks, or by opening the suction valve to disengage the large cylinder.

To communicate the pressure to the large cylinder the ram is made hollow and fitted with a valve bearing against the large ram, which valve will open when the resistance is equal to the pressure on the valve. This arrangement may also be used as a self-acting apparatus in connection with the pipes leading to the cylinders in- [illegible] being part of the rams. The small ram [illegible] hollow, with apertures through its sides to communicate the pressure to the large ram at the end of the first part of the stroke.

Secondly, these improvements relate to those hydraulic presses in which the stroke of the larger ram may be shorter than the lift required for the whole operation. For this purpose the first part of the stroke is effected by means of a cylinder and ram of the requisite length, but small diameter, and therefore of comparatively small weight The large cylinder and its ram, which may rest on the small ram, are made of the length necessary for giving the final pressure. In this case the, fluid is forced into the small cylinder, and when its ram has completed the first part of the stroke, the fluid passes into the large cylinder through a cock or valve forming part of either cylinder or ram, or it may pass through extra pipes to the large cylinder.

Thirdly, these improvements relate to apparatus for supporting the platform or follower, or the cylinder and rams upon which the material to be compressed rests—for instance, when the small ram has completed its stroke. These apparatus consist, again, in small hydraulic cylinders, into which the fluid is allowed to enter, whilst their rams attached to the follower rise through the first part of the stroke. When the rams are not in motion the suction valves will close and prevent the escape of the fluid, which will now support the pressure or weight resting upon them.

Figs. 1, 2, and 3 represents parts of these hydraulic presses in section. Fig. 1 shows an arrangement with the small cylinder placed within the larger one; figs. 2 and 3 represent the small cylinder placed outside the larger one.

A represents the large cylinder; B, the large ram; *a*, the small cylinder; *b*, the small ram; C, the supply pipe for the larger cylinder; *c*, the pipe for the smaller cylinder. Fig. 4 represents, in section, and on a larger scale, a self-acting apparatus through which the fluid from the pumps or accumulator and the reservoir has to pass to reach the cylinders.

In working presses, constructed as shown in figs. 1 and 2, and provided with a self-acting apparatus, as shown in fig. 4, the water, oil, or other fluid is forced by the pumps or accumulator into the self-acting apparatus at *o*, fig. 4, and from there direct through the pipe *c* into the smaller cylinder *a*, the ram *b* of which being against the larger ram B, will move the same till the resistance of the material to be compressed is equal to the force of the small ram *b*. During this part of the stroke the space vacated by the larger ram B is filled up with fluid which enters the cylinder A from a supply reservoir through the pipe *f*, the suction valve *d*, and the pipe *c*, fig. 4.

When the rams have arrived at the end of the first part of the stroke, the fluid under pressure will open the valve *g*, which is weighted accordingly by a spring or weights; the fluid is thus forced through the pipe C into the large cylinder A, the ram B of which will then complete its stroke, and give the final pressure. The fluid is after each operation led back from the cylinders to the pump and supply cistern by opening common stop-cocks, not shown in the drawings; or in order to empty the large cylinder more speedily, the valve *d* may be opened by a screw *p*, as shown in fig. 4, or by any other suitable arrangement.

A press arranged as shown in fig. 3 works in the following manner:—The fluid enters the small cylinder *a* through the pipe *c*; the ram *b* is hollow, and is fitted at the top with a valve *h* bearing against the larger ram B; the valve *h* is pressed slightly against its seating fixed to the top of the small ram *b* by a spring *i*, in order to hold it in its position. The area of this valve *h* is a little smaller than the area of the ram *b*, which will cause the seating *k* to separate from the valve *h* as soon as the resistance of the large ram B or the valve is equal to the pressure of the fluid on the other side of the valve. The large cylinder A, which was supplied during this part of the stroke with the fluid from the reservoir D, through the suction valve *d*, is now open to the action of the pumps, or the accumulator, and the ram B will give the final pressure.

THE BRITISH ASSOCIATION.

Abstract of Inaugural Address of Sir William Armstrong.

The proceedings of the annual meeting of the British Association, held this year at Newcastle-on-Tyne, were commenced on Wednesday evening. A meeting of the members and associates was held at the Town-hall, at which the President for the year, Sir William Armstrong, delivered the inaugural address of which the following is an abstract of portions.

The President commenced by saying that he esteemed it the greatest honour of his life that he was called upon to assume the office of President. In that capacity, and as representing the Association, he must be allowed to advert to the gratifying reception which the British Association met with on their former visit to this region of mining and manufacturing industry; and, as a member of the community which they had again honoured with a visit, he undertook to convey to them the assurance of a renewed and hearty welcome. A quarter of a century had elapsed since the Association assembled in this town, and in no former period of equal duration had so great a progress been made in physical knowledge. In mechanical science, and especially in those branches of it which are concerned in the application of steam power to effect interchange between distant communities, the progress made since 1838 had no parallel in history. The railway system was then in its infancy, and the great problem of trans-Atlantic steam navigation had only received its complete solution in the preceding year. Since that time railways have extended to every continent, and steamships have covered the ocean.

It was chiefly in this locality that the railway system was reared from earliest infancy to full maturity; and amongst the many names associated wit its growth, that of George Stephenson stands preeminent.

In glancing at the history of railways, we may observe how promptly the inventive faculty of man supplies the device which the circumstances of the moment require. No sooner is a road formed fit for wheeled carriages to pass along, than the cart takes the place of the pack-saddle; no sooner is the wooden railway provided, than the waggon is substituted for the cart; and no sooner is an iron railway formed, capable of carrying heavy loads, than the

locomotive engine is found ready to commence its career. As in the vegetable kingdom fit conditions of soil and climate quickly cause the appearance of suitable plants, so in the intellectual world fitness of time and circumstance promptly calls forth appropriate devices. The seeds of invention exist, as it were, in the air, ready to germinate whenever suitable conditions arise, and no legislative interference is needed to ensure their growth in proper season.

To persons who contend that all geological phenomena may be attributed to causes identical in nature and degree with those now in operation, the formation of coal must present peculiar difficulty. The rankness of vegetation which must have existed in the carboniferous era, and the uniformity of climate which appears to have prevailed almost from the Poles to the Equator, would seem to imply a higher temperature of the earth's crust, and an atmosphere more laden with humidity and carbonic acid than exist in our day. But whatever may have been the geological conditions affecting the origin of coal, we may regard the deposits of that mineral as vast magazines of power stored up at periods immeasurably distant for our use.

The principle of conservation of force and the relationship now established between heat and motion, enable us to trace back the effects which we now derive from coal to equivalent agencies exercised at the periods of its formation. The philosophical mind of George Stephenson, unaided by theoretical knowledge, rightly saw that coal was the embodiment of power originally derived from the sun. That small pencil of solar radiation which is arrested by our planet, and which constitutes less than the 2,000-millionth part of the total energy sent forth from the sun, must be regarded as the power which enabled the plants of the carboniferous period to wrest the carbon they required from the oxygen with which it was combined, and eventually to deposit it as the solid material of coal. In our day the reunion of that carbon with oxygen restores the energy expended in the former process, and thus we are enabled to utilize the power originally derived from the luminous centre of our planetary system.

But the agency of the sun in originating coal does not stop at this point. In every period of geological history the waters of the ocean have been lifted by the action of the sun and precipitated in rain upon the earth. This has given rise to all those sedimentary actions by which mineral substances have been collected at particular localities, and there deposited in a stratified form with a protecting cover to preserve them for future use. The phase of the earth's existence suitable for the extensive formation of coal appears to have passed away for ever; but the quantity of that invaluable mineral which has been stored up throughout the globe for our benefit is sufficient (if used discreetly) to serve the purposes of the human race for many thousands of years. In fact, the entire quantity of coal may be considered as practically inexhaustible. Turning, however, to our own particular country, and contemplating the rate at which we are expending those seams of coal which yeild the best quality of fuel, and can be worked at the least expense, we shall find much cause for anxiety. The greatness of England much depends upon the superiority of her coal in cheapness and quality over that of other nations; but we have already drawn from our choicest mines a far larger quantity of coal than has been raised in all other parts of the world put together, and the time is not remote when we shall have to encounter the disadvantages of increased cost of working and diminished value of produce.

After dwelling at some length on the estimated duration of the English coal-fields, Sir William Armstrong went on to say—Were we reaping the full advantage of all the coal we burnt, no objection could be made to the largeness of the quantity; but we are using it wastefully and extravagantly in all its applications. It is probable that fully one-fourth of the entire quantity of coal raised from our mines is used in the production of heat for motive power; but, much as we are in the habit of admiring the powers of the steam-engine, our present knowledge of the mechanical energy of heat shows that we realize in that engine only a small part of the thermic effect of the fuel. That a pound of coal should, in our best engines, produce an effect equal to raising a weight of a million pounds a foot high is a result which bears the character of the marvellous, and seems to defy all further improvement. Yet the investigations of recent years have demonstrated the fact that the mechanical energy resident in a pound of coal, and liberated by its combustion, is capable of raising to the same height ten times that weight. But although the power of our most economical steam-engines has reached, or perhaps somewhat exceeded, the limit of a million pounds raised a foot high per lb. of coal, yet, if we take the average effect obtained from steam-engines of the various constructions now in use, we shall not be justified in assuming it at more than one-third of that amount. It follows, therefore, that the average quantity of coal which we expend in realizing a given effect by means of the steam-engine is about thirty times greater than would be requisite with an absolutely perfect heat-engine.

The causes which render the application of heat so uneconomic in the steam-engine have been brought to light by the discovery of the dynamical theory of heat; and it now remains for mechanicians, guided by the light they have thus received, to devise improved practical methods of converting the heat of combustion into available power.

Engines in which the motive power is excited by the communication of heat to fluids already existing in the aeriform condition, as in those of Stirling, Ericsson, and Siemens, promise to afford results greatly superior to those obtained from the steam-engine. They are all based upon the principle of employing fuel to generate sensible heat, to the exclusion of latent heat, which is only another name for heat which has taken the form of unprofitable motion amongst the particles of the fluid to which it is applied. They also embrace what is called the regenerative principle—a term which has, with reason, been objected to, as implying a restoration of expended heat. The so-called "regenerator" is a contrivance for arresting unutilized heat rejected by the engine, and causing it to operate in aid and consequent reduction of fuel.

It is a common observation that before coal is exhausted some other motive agent will be discovered to take its place, and electricity is generally cited as the coming power. Electricity, like heat, may be converted into motion, and both theory and practice have demonstrated that its mechanical application does not involve so much waste of power as takes place in a steam-engine; but whether we use heat or electricity as a motive power, we must equally depend upon chemical affinity as the source of supply. The act of uniting to form a chemical product liberates an energy which assumes the form of heat or electricity, from either of which states it is convertible into mechanical effect. In contemplating, therefore, the application of electricity as a motive power, we must bear in mind that we shall still require to effect chemical combinations, and in so doing to consume materials. But where are we to find materials so economical for this purpose as the coal we derive from the earth and the oxygen we obtain from the air? The latter costs absolutely nothing; and every pound of coal, which in the act of combustion enters into chemical combination, renders more than two and a half pounds of oxygen available for power. We cannot look to water as a practicable source of oxygen, for there it exists in the combined state, requiring expenditure of chemical energy for its separation from hydrogen. It is in the atmosphere alone that it can be found in that free state in which we require it, and there does not appear to me to be the remotest chance, in an economic point of view, of being able to dispense with the oxygen of the air as a source either of thermo-dynamic or electro-dynamic effect. But, to use this oxygen, we must consume some oxidizable substance, and coal is the cheapest we can procure.

With regard to smoke, which is at once a waste and a nuisance, having himself (the President) taken part with Dr. Richardson and Mr. Longridge in a series of experiments made in that neighbourhood in the year 1857-58, for the purpose of testing the practicability of preventing smoke in the combustion of bituminous coal in steam-engine boilers, he could state with perfect confidence that, so far as the raising of steam is concerned, the production of smoke was unnecessary and inexcusable. The experiments to which he referred proved beyond a doubt that, by an easy method of firing, combined with a due admission of air and a proper arrangement of firegrate, not involving any complexity, the emission of smoke might be perfectly avoided, and that the prevention of the smoke increased the economic value of the fuel and the evaporative power of the boiler. As a rule, there is more smoke evolved from the fires of the steam-engines than from any others, and it is in these fires that it may be most easily prevented. But in the furnaces used for most manufacturing operations, the prevention of smoke is much more difficult, and will probably not be effected until a radical change is made in the system of applying fuel for such operations.

Sir William, after some further remarks on coal, the power of water, Siemen's furnaces, &c., adverted to Mr. Nasmyth's remarkable discovery, that the bright surface of the sun is composed of an aggregation of apparently solid forms, shaped like willow-leaves or some well-known forms of Diatomaceæ, and interlacing one another in every direction. The forms are so regular in size and shape as to have led to a suggestion from one of our profoundest philosophers of their being organisms, possibly even partaking of the nature of life, but at all events closely connected with the heating and vivifying influences of the sun. These mysterious objects, which, since Mr. Nasmyth discovered them, have been seen by other observers as well, are computed to be each not less than 1,000 miles in length and about 100 miles in breadth. The enormous chasms in the sun's photosphere, to which we apply the diminutive term "spots," exhibit the extremities of these leaf-like bodies pointing inwards, and fringing the sides of the cavern far down into the abyss. Sometimes they form a sort of rope or bridge across the chasm, and appear to adhere to one another by lateral attraction. He could imagine nothing more deserving of the scrutiny of observers than these extraordinary forms. The sympathy, also, which appears to exist between forces operating in the sun and magnetic forces belonging to the earth, merits a continuance of that close attention which it has already received from the British Association, and of labours such as General Sabine has with so much ability and effect devoted to the elucidation of the subject. He then noticed that most remarkable phenomenon which was seen by independent observers at two different places on the 1st of September, 1859. A sudden outburst of light, far exceeding the brightness of the sun's surface, was seen to take place, and sweep like a drifting cloud over a portion of the solar face. This was attended with magnetic disturbances of unusual intensity, and with exhibitions of aurora of extraordinary brilliancy. The identical instant at which the effusion of light was observed was recorded by an abrupt and strongly-marked deflection in the self-registering instruments at Kew. The phenomenon as seen was probably only part of what actually took place, for the magnetic storm in the midst of which it occurred commenced before and continued after the event.

In referring to the science of gunnery, to which he made but slight allusion on this occasion, he stated that it was intimately connected with the dynamical theory of heat. When gunpowder is exploded in a cannon, the immediate effect of the affinities by which the materials of the powder are caused to enter into new combinations, is to liberate a force which first appears as heat, and then takes the form of mechanical power communicated in part to the shot and in part to the products of explosion which are also propelled from the gun. The mechanical force of the shot is reconverted into heat when the motion is arrested by striking an object, and this heat is divided between the shot and the object struck, in the proportion of the work done or damage inflicted upon each. These considerations recently led him, in conjunction with his friend, Captain Noble, to determine experimentally, by the heat elicited in the shot, the loss of the effect due to its crushing when fired against iron plates. Joule's law, and the known velocity of the shot, enabled us to compute the number of dynamical units of heat representing the whole mechanical power in the projectile, and by ascertaining the number of units developed in it by impact, we arrived at the power which took effect upon the shot instead of the plate. These experiments showed an enormous absorption of power to be caused by the yielding nature of the materials of which projectiles are usually formed; but further experiments are required to complete the inquiry.

Whilst speaking of the subject of gunnery, Sir W. Armstrong paid a passing tribute of praise to that beautiful instrument invented and perfected by Major Navez, of the Belgian Artillery, for determining, by means of electro-magnetism, the velocity of projectiles. This instrument has been of great value in recent investigations, and there are questions affecting projectiles which we can only hope to solve by its assistance. Experiments are still required to clear up several apparently anomalous effects in gunnery, and to determine the conditions most conducive to efficiency both as regards attack and defence.

After alluding to Professor Tyndal's researches on heat, the balloon explorations of Mr. Glaisher, the electric telegraph, the metric system, Darwin's theory, &c., Sir William Armstrong concluded his address by saying, "I will not run the risk of wearying this assembly by extending my remarks to other branches of science. In conclusion, I will

press a hope that when the time again comes round to receive the British Association in this town, its members will find the intervals to have been as fruitful as the corresponding period on which we now look back. The tendency of progress is to quicken progress, because every acquisition in science is so much vantage-ground for fresh attainment. We may expect, therefore, to increase our speed as we struggle forward; but however high we climb in the pursuit of knowledge, we shall still see heights above us, and the more we extend our view, the more conscious we shall be of the immensity which lies beyond."

SCIENTIFIC SOCIETIES.

Meeting in the Ensuing Week.—London Association of Foremen Engineers, Saturday the 5th prox., at 8 p. m. Paper to be read by Mr. Gettcliffe on "An Apparatus for Preventing Boiler Explosions."

TO CORRESPONDENTS.

Received.—D. S. F.—W. M. R.—T. M.—T. W. and Co.—C. B. L.

C. (Belfast).—We cannot advise you.

T. Swan (Tring)—Patented three or four times over.

A Pewterer (Birmingham).—You cannot. The French Government prohibits the employment of more than 18 per cent. of lead in the manufacture of pewter.

Gozzan.—Try one of Bastier's chain-pumps. It has been used very successfully to drain shallow mines.

Correspondence.

SPEED FOR THE NAVY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—In your number for August 7th you inserted a very well written letter from Capt. Halsted, in which the writer attempts to show that our ships of war should be completely armoured from stem to stern. I think, however, that it is now pretty certain that we cannot get a high speed out of a completely armoured ship, unless the size is increasad to an inconvenient extent; and I think also that the "Alabama" has proved conclusively that speed is a far more important element in the qualities of a man-of-war that even partial invulnerability.

Let the fighting portion of a ship be as invulnerable as possible, with 5 in. iron bulk-heads fore and aft, and make it large enough to contain everything you require for a long voyage and for attack and defence; so far, well; but why cannot a long bow and fine run be added to this fighting portion *merely for speed?* Put nothing at all, if you like, in these parts of the vessel but a foremast and mizenmast; and then why should they be loaded with 4½ or 5 in. plates? Without them she may be made to steam 20 miles an hour, but not with them. Capt. Halsted says that these portions of a ship would form the *targets* for the enemy to fire at! I can only say that if he was foolish enough to waste his ammunition in that way, I think the other Captain would be trying to touch him in a more vital part; and if I were on board I should be tempted to add a broomstick to the bowsprit to tempt him to waste his ammunition on *that*, because it is not covered with armour.

There are ships in the Navy that would be greatly improved in speed by adding a false bow to them, but may not this be added without armour plates being hung upon it?

When ships were 200 ft. long their broadsides were considered amply sufficient, yet when their lengths were increased, it seems to have been considered essential to have guns from stem to stern of the increased broadside; but if the builders had retained the old broadside for guns, and allowed the increased length to be merely for speed, the ships would have been better sea-boats and faster sailers.

If we were at war with another Power, and all our ships of war were constructed according to Capt. Halsted's notions, the enemy would only have to fit up a few "Alabamas" in order to commit depredations upon our mercantile marine, and while our ships would be always ready to fight, they could never be able to get to the spot where fighting is useful—alongside the enemy.

I see no reason why our ships of war should not be the fastest vessels afloat, under steam, as they once were under sail, and not another vessel ought to be built which cannot steam 20 miles an hour; and for this purpose, light and fine ends and light engines with high pressure steam are absolutely necessary.

I am, Sir,
Your very obedient servant,
Clifford's Inn. T. Moy.

TORPEDOES.

Sir,—I have read with great pleasure your leader of yesterday. Upon the necessity of high speed in war vessels we quite agree; but high speed, with weighty armaments and equipments, is hardly attainable.

I have refrained, of late, to address you upon the subject of the employment of submarine explosive shells in naval warfare. My thoughts have not, however, been diverted from that important matter; and I remain in the *confident* belief I have entertained over a period of eighteen years, that vessels armed with cannon cannot successfully combat, on the ocean, with vessels armed with submarine explosive shells; presuming such vessels to be adapted to the service of the arm.

From the accounts I have read of the American torpedoes, I do not think the Americans understand the subject. I could, perhaps, enlighten the Confederates to an extent that would enable them to free themselves of the annoyance of the blockade of their ports, but that would be acting in a manner at variance with the Queen's proclamation of neutrality which her subjects *ought* to respect, especially those who are servants of the Crown.

When, however, the war shall have terminated between the Federals and Confederates—or should it take a turn that it may be legal to aid the State that has no *aggressive* intention, but simply a desire to defend its shores and commerce—there will be no objection to render such State a service that, I doubt not, will be gladly accepted.

With regard to our interest, England has paid dearly enough for experiments in war engines; and she is now wasting her skill and labour in experiments upon war vessels, which in time of need will, I venture to predict, prove worse than useless. These monsters, constructed and equipped at an outlay of about £200,000 each, and upon which great reliance is being placed, can, I do positively assert, be easily rendered unseaworthy or be destroyed by about £40 worth of explosive composition. In the event of war, they would be in imminent danger, in protecting our commerce, when opposed by submarines; they could not pursue vessels, of comparatively pigmy dimensions, armed with submarine shells, without great risk of either being disabled, by their propellers, rudders, and sternposts being blown away; or of being sunk, or of being blown up by their own powder, should one or more explosive shells take effect under their magazines.

It has been my good fortune to become acquainted with an eminent chemist—John Horsley, F.C.S., Analyst for the County of Gloucester—who has for some years past given his attention to explosive compounds; to him I am indebted for a compound, admirably adapted to the service of submarine explosive shells, two hundred pounds weight of which would, in destructiveness, when applied to, and exploded under, and in *hugging* contact with a vessel's bottom, be, I think, equal to eight hundred pounds weight of the best cannon powder.

In conclusion, since I am confident that I have taken a correct view of the matter, the sooner the authorities to whom our defences are entrusted are brought to a comprehension of it, the better; even if such knowledge be forced upon them by any foreign State that may have but little regard for routine modes of proceeding.

Pardon this interruption, and believe me,

Yours sincerely,
Jn. Harvey.

5, Keynsham Parade, Cheltenham,
August 22, 1863.

P.S.—I have just seen, in this day's *Times*, an account of a torpedo being exploded by a vessel passing up the River St. James. If the statement of such explosion is correct, the torpedo could not, I think, have exploded *under* the vessel's bottom, which it ought to have done, and in *hugging* contact, too. I think it exploded *near* the *side* of the vessel, but not in contact with the side. The lift of 10 ft. may prove to be a *heel* of 10 ft.

MEASURING THE LENGTH OF A CIRCLE BY A STRING.

Sir,—In your number for July 10, p. 496, your correspondent, Mr. Denison, says:—"Measuring the length of a circle by a string is hardly a recognized mathematical operation; but the construction of a circle is."

I agree that string is unmathematical; but I should feel obliged if Mr. Denison would let us see any simple mode of constructing a cycloid—still more a simple mode of measuring its base.

Yours, &c.,
August 26, 1863. R. N.

Miscellanea.

We announce, with regret, the death of William Templeton, a gentleman whose contributions to engineering literature have been generally esteemed. There is scarcely an establishment in England where his "Workshop Companion" is not in daily use; and his other works, though few, have proved extremely useful to the young engineer.

Experiments at Newhaven show that the 110-pounder breech-loading Armstrong guns will only take 12 lb. charges. The guns, therefore, are of too small power for the broadside of ships; and, consequently, at present there is no cannon fit for arming the iron-plated ships.

Mr. Reed's experimental iron-cased sloop "Enterprize," built at Deptford, is now receiving her armour casing, which is bent in Woolwich dockyard and forwarded to the ship, ready to be applied. A couple of the plates, 15 ft. by 14 ft. 9 in. each, have been fitted to the sides, and two others are ready to be forwarded. The whole of the plates will be supplied by Mr. Brown, of Sheffield, who made a large proportion of those used in the "Caledonia."

Mr. Reuter's proposal to erect and maintain a line of telegraphic communication from Cork to Crookhaven and Cape Clear, in order to meet the steamers, and obtain the American mails some hours earlier than at present, has been accepted.

The cylinder of an engine attached to one of the trains of the Metropolitan Railway burst on Sunday afternoon from some unexplained cause, and, although no one was injured, a great deal of inconvenience was experienced by large numbers of would-be passengers at Farringdon-street.

On the 25th of June last, Mr. Mohr observed, at Coblentz, a rainbow completely red. The exterior of the bow was very bright, fading away towards the interior edge. Such a phenomenon is very rare.

A vein of magnetic iron has recently been discovered in Sweden which is probably the richest of all the known sources of natural magnets. This vein which is some feet thick, traverses a mountain formed of minerals more or less magnetic, situate on the left hand of the river Bautusjoki, in latitude 67½ deg., and longitude 39¾ deg. Put in connection with the galvanometer, some of these natural magnets produced a deviation of 10 to 15 deg., and a very short contact sufficed to convert a piece of iron into a magnet capable of sustaining a weight of 1 lb. or 2 lb. Swedish. Natural magnets weighing 400 livres from this vein are easily obtained, their price varying from 80 centimes to 3 francs the kilogramme.

A letter from Constantinople, dated August 20, says:—The statements published by some journals relative to the Suez Canal settlement are erroneous. Forced labour is absolutely abolished, the company having six months allowed them to make other labour arrangements.

A train conveying petroleum recently took fire on the Pennsylvania railroad, and the heat was so intense that the cross ties of the track on which the cars stood, and also of the track adjoining, were burned through, and the rails so warped as to render it difficult for trains to pass. The foliage of the trees was burned off and shrivelled for a distance of 50 ft. on either side of the track.

The "Marian Moore" a transport vessel, has left the Thames, having on board 900 miles of electric telegraph wire, &c., which was shipped at the works of Messrs. Henley, North Woolwich, to be laid down in India.

The Malta and Alexandria telegraph cable is now finally repaired, and messages can now be taken direct from London to Suez to catch the Indian, China, and Australian mails at Suez.

A new traction engine for the prairies is thus described by an American paper:—"An engine, built by John A. Reed, an eminent and skilful inventor, arrived in Nebraska City a year ago. It will draw eight tons of freight up a grade of 600 ft. to the mile, nearly twice as steep as the heaviest railroad

grade. The tread wheels are ridged to prevent slipping. This machine, being the first one built, is propelled by four engines of ten horse-horse power each. The cylinders are oscillating, and connect with shafts, upon which are pinions of 12 in. diameter, which move upon and give motion to wheels, about 6 ft. in diameter, which are attached to the inside of the spokes of the driving wheels. The drivers are 10 ft. in diameter, made of boiler iron, and have a thread of 18 in. The steering wheel is 6 ft. in diameter, and attached at the middle of the axle to the forward end of the tank by a ball and socket arrangement. The tank forms the body of the waggon. The boiler is an upright tubular, and aft the driving shaft. The waggon will carry wood and water sufficient for a four hours' run. It consumes one cord per eight hours. The hands required to run the steam waggon are—an engineer, fireman, and pilot."

The "Lord Warden," the new iron-cased frigate to be built at Chatham, will be covered with one uniform thickness of iron plates. Another important feature in the "Lord Warden" will be the placing of a powerful battery of guns, in which she will differ from all vessels of war afloat. This battery will be so placed as to enable the guns to be fired straight ahead, while the solid iron-plated bow will be carried up sufficiently high to form a sort of tower, in which the guns will be placed. The extremity of the front will be furnished with a huge steel stem, shaped somewhat like a cleaver; and this formidable weapon will, it is confidently anticipated, cut completely through a hostile ship, when used as a ram, as, from the enormous size and momentum of a vessel of the "Lord Warden's" dimensions, one, or, at most, two blows would be sufficient to sink the largest vessel afloat. Another vessel of the same kind is to be built at Pembroke, and to be named the "Lord Clyde."

A most importment announcement was made at a ship launch on the Mersey last week. Messrs. Potter and Co. despatched from the stocks a new iron vessel of 1,200 tons, built for Messrs. Boult, English, and Brandon. After the launch about 200 guests partook of lunch in the mould loft; and Mr. T. M. Mackay, of London, in proposing "Prosperity to the good ship 'Bedfordshire' and her worthy owners," made the following remarks relative to the difficulties encountered by the builders of the vessel, owing to the opposition of workmen engaged in the iron shipbuilding trade. Mr. Mackay said:—"Mr. Potter's greatest difficulty to be encountered was the organized opposition of workmen, who, in defiance—I regret to say ignorant defiance—of all the laws of political economy, still allow themselves to be led by the nose to their own ruin and discomfiture, by being really under the terrorism of what I may say, in every sense of the word, is 'club law.' Well, Mr. Potter was not daunted by this. He took into consideration the intelligence of the shipwrights in their manipulation of wood, and believed they might turn advantageously to the manipulation of iron; and bearing in mind that care and attention, far more than dexterity, which is the result of long practice, is necessary, he called the shipwrights of Liverpool into requisition, and the ship you have seen launched to-day is their maiden effort—(loud cheers); and I challenge all the boiler-makers of Liverpool to show me a ship in which the work has been more honestly performed, or in which there is a more perfect finish than in the 'Bedfordshire.' (Loud and repeated cheering.) Now, ladies and gentlemen, there is more involved in this than you would at first suppose, from the fact of a vessel constructed of iron being manufactured by shipwrights who have always wrought in wood, and have never been accustomed to work at iron. But when we consider the great revolution that is taking place in the building of ships—in the change from wood to iron—it is most important to find the aptitude of our mechanics for this change; because it enables them to place us more forward than ever as a nation in the rank of maritime power." (Hear, hear.)

A curious communication was recently sent in to the Academy of Sciences, by M. Morvan, in which he describes a method of his for obtaining direct photographic impressions upon stone, and which he can afterwards print off. He first gives the stone a coating, which he applies in the dark, of a varnish composed of albumen and bi-chromate of ammonia. Upon this he lays the right side of the image to be reproduced, whether it be on glass, canvas, or paper, provided it be somewhat transparent. This done, he exposes the whole to the action of light, for a space of time varying between thirty seconds and three minutes if in the sun, and between ten and twenty-five minutes if in the shade. He then takes off the original image, and washes his stone, first with soap and water, and then with pure water only, and immediately after inks it with the usual inking roller. The image is already fixed, for it begins to show itself in black on a white ground. He now applies gum water, lets the stone dry, which is done in a few minutes, and the operation is complete. Copies may at once be struck off by the common lithographic process.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

161. H. Rushton. *Improvements in machinery for plaiting cotton, thread, or other fibrous material over steel for crinolines, and in the mode of securing the plaiting to prevent it slipping thereon.* Dated January 19, 1863.

This invention consists—1, instead of having a series of dogs or beaters for changing the direction of the tubes, in fixing a series of projections on the circular bar in lieu thereof, thus obtaining greater certainty in controlling the tubes, and increasing the durability of the machine. 2, in giving motion to the circular bar by using a cam made by a groove of suitable shape, in which works a pin attached to the circular bar. The thread plaited over the steel is attached thereto, and prevented from shifting or slipping thereon, by the application of a quickly drying size or varnish upon the surface of the steel; the size is applied by passing the steel between two rollers in the machine, which are covered with flannel, saturated and kept well supplied with the size. *Patent abandoned.*

162. R. A. Brooman. *Improvements in the manufacture of sulphate of soda for conversion into soda and other uses.* (A communication.) Dated January 19, 1863.

When a mixture of coal, sulphuret of iron, and chloride of sodium is heated in the presence of air, sulphate of soda, oxide of iron, and chloride of iron are formed; the proportion of these different bodies varies with the quantities of the substances above named forming the mixture, as also the state of division when used. This invention consists in manufacturing sulphate of soda by reducing to a powder the fuel (charcoal, coal, coke, or other fuel), the natural or artificial sulphuret of iron, and the salt, and in mixing these substances in certain fixed proportions. *Patent completed.*

163. W. H. Harrison. *Improvements in covering wire and other iron articles for the purpose of preventing them from oxidation, and in the mode or method employed therein.* Dated January 19, 1863.

This invention consists in immersing the object to be protected first in a bath of metallic alloy in which lead is present, but of which tin or zinc forms a large proportion; then, after the object has been so coated, treating it mechanically by drawing, rolling, or burnishing, and afterwards immersing the object so coated and treated in a second bath of suitable alloy, composed entirely or nearly entirely of lead, tempered or regulated in its degree of metallic hardness by the addition of bismuth, or other suitable metal, when the article may again be submitted to mechanical treatment as before. *Patent abandoned.*

164. J. J. Lundy. *Improvements in the manufacture of metallic casks and vessels.* Dated January 19, 1863.

According to the common and generally adopted system of manufacture of metallic casks and similar vessels, the bottom end only is swaged into the body of the cask as a fixture, whilst the other end is attached by circumferential straps, or bent holding pieces, with rivets. These holding straps are attached to the exterior of the end of the cask; when the end or head-piece is inserted they grasp the dished flange of the end or head-piece, and thus prevent the latter from moving upwards. And, further, to prevent the end or head-piece from sinking within the cask, the small handle attached to the centre of the head has to be elongated at each end, these ends being converted into bent holding strap pieces to grasp the end rim of the cask. Now, according to the present invention, instead of using the details above described, the dished end or head-piece is swaged firmly in its place with a holding and tightening bead, after the manner commonly adopted for the lower end, which is far simpler and stronger. This makes a perfectly secure and neat cask, and the handle needs no elongation whatever, besides being cheaper in its production than by the old system of closing up the cask when filled with paint or any other substance. *Patent completed.*

165. B. Van der Mark. *A musical instrument called "Mark-harmonica."* Dated January 19, 1863.

The chief aim of this invention is intended to facilitate part-singing of hymns and sacred music at family worship, to encourage the study of vocal music, to promote congregational singing in all churches and chapels, and effective teaching in families and schools. The instrument assumes different shapes, according to the number of performers for which it is intended, viz.:—If for four performers, the instrument may conveniently assume the form of a table, by preference 3 ft. long, 2 ft. 6 in. wide, and 2 ft. 8 in. high, or thereabouts; if for six performers, the form of a hexagon; and if for eight performers, the form of an octagon. The instrument is divided into separate compartments for soprano, alto, tenor, and bass, each compartment containing the full compass of one of these parts; if for six performers, the compartments would, by preference, be as follows—two sopranos, two basses, alto, and tenor; and if for eight performers—two sopranos, two altos, two tenors, and two basses. There are, consequently, either four, six, or eight distinct key-boards to perform upon. Stops may be used instead of keys; and to simplify the performance, each stop is numbered for the guidance of the player, each performer having his own separate part before him, and singing and playing the note marked. The union of voices and players will thus produce vocal harmony with instrumental accompaniment. The sound of each note is produced by a brass or other metallic vibrator through the agency of bellows. The action of one foot will generally be sufficient to feed the instrument with air. *Patent abandoned.*

166. A. Paul. *Improvements in obtaining reciprocating motion in steam engines, and for communicating the same to any ordinary pumps, for whatever purpose they may be employed.* Dated January 20, 1863.

We cannot here give space to the voluminous details of this invention. *Patent abandoned.*

167. J. Mosheimer. *Improvements in machinery for crushing and grinding quartz and other substances.* Dated January 20, 1863.

This invention consists in combining in the same machine the two principles of crushing and grinding quartz and other substances—1, The quartz or other substances is crushed by centrifugal force, and then it is ground fine by a suitable grinding machine. In reference to the first operation, the patentee observes that, if a piece of rock or ore be let fall on to a hard surface from a given height, it will in proportion to the height from which it has fallen, be more or less broken to pieces; therefore, if force be employed to throw a piece of quartz at, for instance, the velocity of 600 ft. per minute against a solid piece of iron, such a tremendous blow is given to the quartz that it will be thrown back and shattered to pieces, and in course of time, if the blows be repeated, the quartz will be reduced to as fine a state as may required; but in order that every particle which escapes reduction by this operation may be reduced to powder, he places under the above crushing machine a grinder which acts on the plan of a grinding mill. This grinder is constructed of iron, and is kept cool by a continual stream of water which is made to pass through its centre. *Patent completed.*

168. J. Bell and J. Speight. *Certain improvements in the construction of carding engines.* Dated January 20, 1863.

This invention consists in an improved mode of constructing the adjustable bearings in which the working and stripping rollers revolve. To the bend or other part of the framing of the carding engine are cast cylindrical studs in the usual manner; on these studs are fixed the adjustable bearings; the plates are provided with toothed racks, and the bearings are furnished with short worms gearing into the racks on the plates. The axle of the worm projects beyond the end of the bearing, and is made square, or of other suitable shape, to receive a screw key. By turning the worm round, the distance between the surfaces of the main cylinder and the working and stripping roller can be adjusted accurately and expeditiously. The worms are made by preference of malleable cast iron. *Patent abandoned.*

169. W. Mawson and J. Whitehead. *Improved hydraulic machinery for raising water in mines, wells, and other places.* Dated January 20, 1863.

The object and intention of this invention is to dispense with the necessity for employing stuffing-boxes in hydraulic machines, and thereby to avoid friction at such parts. The inventors propose to effect this by the following means:—The piston plunger or ram is formed less in diameter than the bore of the cylinder in which it works, and to the bottom of the said ram a piece or pieces of leather of annular circular form is or are affixed, so that the water pressing against the said leather forces it against the circular bore of the cylinder, and makes a perfectly water-tight joint. They propose to form the cylinder of a solid square piece of metal, bored out at its centre, and open at top (having no stuffing-box) to receive the ram. The said cylinder is to be fitted in an oblong cistern containing water; two small pumps fitted with suitable valves are also fitted on the said cistern, and the pumps are worked by a two-throw crank-shaft for injecting water into the square cylinder aforesaid, for lifting the ram and imparting motion to a long lever, an anti-friction roller being adapted to the head of the ram

upon which the said lever rests. The short end of this lever has its fulcrum on a strong pin fixed in a standard, and the longer end of the said lever is connected to the pump rod leading down the shaft of the mine, pit, or other place from which the water is to be raised. By these means a great saving of power may be effected. *Patent abandoned.*

170. H. A. Bonneville. *Improvements in the manufacture of clocks.* (A communication.) Dated January 20, 1863.

This invention consists in regulating the working of clocks by means of the oscillations of a spiral spring with a circular balance wheel, instead of an ordinary pendulum. *Patent abandoned.*

171. H. A. Bonneville. *Improvements in colouring, bronzing, and preserving iron and steel.* (A communication.) Dated January 20, 1863.

The patentee claims—1, The creation at the surface of the iron or steel of an adherent coat of peroxide of iron. 2, The transformation, under the influence of water at an elevated temperature, of the peroxide of iron into black oxide which is less oxidized. 3, The renewing of the operation until this black coat is sufficiently thick and adherent. 4, The immersion of the articles in a bath of lukewarm water, for the purpose of removing the acidulated or saline particles adhering to their surfaces, and allow of being greased with olive oil. *Patent completed.*

172. M. Henry. *Improvements in apparatus for retarding and stopping railway carriages.* (A communication.) Dated January 20, 1863.

This invention relates to the mode of stopping or retarding carriages on railways, and consists of improved apparatus for the purpose, in which apparatus for working the breaks is so combined with the apparatus for connecting or coupling the carriages that the breaks are applied and caused to stop or retard the carriages by the action of uncoupling or disconnecting the carriages from each other. This may be done, in one arrangement, by a chain or like agent extending to within easy reach of the driver or other attendant of the train, and connected under each carriage to a bar, rod, or shaft, hereinafter called the "disconnecting shaft." Each coupling hook is held to the carriage by a bar, rod, or piece, herein called a "key," kept in place by a moveable notched or hooked piece connected to the disconnecting shaft by a crank, link, or jointed lever. When the chain is pulled or drawn, the disconnecting shaft is turned partially round or oscillated, so as to move the notched or hooked piece and release the key therefrom, whereupon the key will be forced upward (or in the required direction) by a spring, and will liberate the coupling hook from the carriage, the momentum of the latter facilitating the action. The same action of the disconnecting shaft that disconnects the carriage also works the breaks. *Patent abandoned.*

173. W. Clark. *Improvements in looms for weaving textile fabrics.* (A communication.) Dated January 20, 1863.

This invention consists in weaving fabrics in a circle, or any part of a circle, and in rising a plurality of shuttles passing through a warp or web at the same time, and in carrying the shuttle or shuttles through the warp by means of friction rollers, pulleys, belts, or their equivalents, and by beating up the weft or filling in sections. *Patent completed.*

174. J. Smith and S. A. Chease. *A new description of motive-power engine, to be called the "Displacement Engine."* Dated January 20, 1863.

This invention consists in certain mechanical appliances so arranged as to co-operate with the motive power of air and water, each of these powers being subject to the action of gravitation in proportion to its ponderability. *Patent abandoned.*

175. H. Hughes and J. Sanders. *Improvements in machinery and apparatus for the manufacture of trimmings and cap-fronts.* Dated January 20, 1863.

This invention consists in constructing machines for making, and apparatus for folding, trimmings and cap-fronts as hereafter described. These trimmings and cap-fronts consist of loops of ribbon, chenille, silk, or other fabric, with or without goffered net or quilling between the ribbons. The inventors take a roller or mandril, the shape and size of which may be varied, and they mount this roller in a frame in such manner that it may be made to rotate. The roller is formed of two halves or otherwise, so as to leave two grooves along its whole length; in each of these grooves they place two strips of net or other foundation, covered with gum or other adheive material, or they lay on the strips gummed thread to cause the ribbon to adhere to the foundation strips. They place a threaded shaft parallel with the grooved roller, and through a nut they connect a bobbin or reel, carrying the ribbon to be used in forming the trimming or cap-front to the threaded shaft. In some cases, for the purpose of varying the trimming or front, they use two or more different ribbons, and lay them alternately; they connect as many bobbins to the shaft as there are different ribbons. By wheel-work they drive both roller and threaded shaft from one main wheel, but other gear may be used. Supposing the machine ready to work, they fix one end of the ribbon from the bobbin on the grooved roller, and cause both roller and shaft to revolve; the bobbin will be carried along the machine, and the roller will wind in itself the ribbon from the bobbin. When the ribbon becomes wound on its whole length, it is dried, a knife or cutter is run along each of the grooves, and the ribbon thereby severed. The fabric removed will be in the form of two sets of strips of ribbon, the ends of which will be united to the two longitudinal strips of gummed foundation. Or, before being dried, the material may be dressed. The strips of ribbon may be embossed or not, as desired; and the strips or ribbon being doubled or folded the two foundation strips are brought one over the other, and are secured by a banding machine or by sewing in a sewing machine, or otherwise. The strips of ribbon may be partly or entirely goffered or not. For inserting the goffered net between the ribbons, they use an apparatus made with flaps to fold over and hold down the foundation strips, while the goffered net is being inserted. The strips of ribbon are received in a hinged "making-up" box; they use a guide for the insertion of the goffered net; and after the strips of ribbon have been placed in the box and the edges held down by the flaps, the goffered net is inserted, one flap removed, and the strips of ribbon folded over the net, the box is then turned over, leaving part of the foundation strips exposed. The remaining flap or flaps are then removed, and the making-up box with its contents is taken away. The protruding edges are caused to adhere by means of a heated press. *Patent abandoned.*

176. S. Blackwell. *Improvements in apparatus for applying water or other fluid to the legs and other parts of horses and other animals.* Dated January 20, 1863.

For the purposes of this invention, in order to apply water or other fluid continously for any desired length of time to the leg of a horse, or any other animal, with a view to cool, foment, or poultice the same, a hollow tube or band (which, by preference, is composed of galvanized india rubber) is used; this is perforated with numerous small holes, so as to divide the water or fluid into numerous small streams. The ends of this perforated tube or hollow band are closed, and a flexible supply pipe is connected to the hollow perforated band or tube, whilst the other end of the supply tube is connected to a vessel containing water or other fluid. To regulate the flow of the fluid, the supply tube may have a valve or cock applied to it. The vessel which contains the water or other fluid is arranged to be fastened on the back or other part of a horse; or it may be otherwise placed and supported when circumstances require it. The perforated tube or band is attached to or around the leg by a strap or otherwise. When desired, sponge or other porous and absorbent covering may be placed and secured over the part of the leg where the fluid is to be applied, so as to act as a poultice, or the water or fluid may be caused simply to flow in numerous streams over the parts of the leg requiring such treatment. *Patent completed.*

177. J. W. Meeks. *A new and improved method for making sash-frames and sashes, and suspending the same by atmospheric pressure or otherwise.* Dated January 21, 1863.

For the purpose of this invention, instead of suspending and working the sash as at present, by lines, weights, and pulleys, the patentee fits it with tubes of elastic material charged with atmospheric air or with gas. These tubes are attached to the sash one on each side thereof, in a groove or recess therein, and (when working with the sash) they slide up and down in corresponding grooves or recesses in the joints or fixed sash frame or window frame, and thus retain the sash at any required height in the frame. Each such groove or recess may be semicircular, or semi-elliptical, in horizontal section, and, when the sash is in the frame, each recess in the sash has opposite to it a corresponding recess in the fixed sash frame or jamb, such two opposite recesses, when together, form a cylindrical or elliptical space, in which is the tube fitting closely, one half in the sash groove and the other half in the frame or jamb groove. The tubes are made of caoutchouc, gutta percha, or of caoutchouc or gutta percha compounds, or of other flexible and elastic material, and are hermetically closed or secured at both ends. They are charged, with pumping or otherwise, with air or gas under such pressure as may be required to sustain the weight of the sash by means of any suitable apparatus for injecting the air or gas, and closing the same when filled, as is well understood. *Patent completed.*

178. A. Phillips. *Improvements in looms for weaving figured fabrics.* Dated January 21, 1863.

The patentee claims—1, The system or mode of weaving figured fabrics by means of the mechanical arrangement or combination of parts described. 2, The system or mode of forming the loops on the surface of the figured fabrics by means of a series of loop-formers, upon which the woollen weft is indented in the manner described. 3, The system or mode of forming the loops or indenting the weft of figured fabrics produced according to this system of weaving by means of a series of loop-forming levers, which operate in conjunction with the loop-formers, together with the arrangement for actuating the levers, or any mere modification of the same, as described. *Patent completed.*

179. T. Wright. *Improvements in the manufacture of cast-iron pipes, and the apparatus employed for the purpose.* (A communication.) Dated January 21, 1863.

Provisional protection has not been granted for this invention.

180. F. A. Busch. *Improvements in the manufacture of metallic vessels or receptacles for containing liquids or substances.* Dated January 21, 1863.

In carrying out this invention, the inventor proposes to form the vessels, whether in the form of bottles, jars, or otherwise, of a base metal, such as iron, and to immerse them in a bath or solution of a noble metal, such as platinum, silver, or gold, bringing the poles of a galvanic battery to bear upon the articles and upon plates of the desired noble metal, whereby the plates will become dissolved and the metal deposited on the interior and exterior surface of the base metal, thus producing a surface capable of withstanding oxidation and the effects of acids or solutions. *Patent abandoned.*

181. J. M. Kirk. *Improvements in finishing textile fabrics.* Dated January 21, 1863.

This invention consists—1, in the employment of thin metal plates, instead of press papers, for placing betwixt the folds of the textile fabrics to be pressed, which plates are heated by any suitable means previous to the placing of them in the folds. 2, in the employment of a series of hollow metal plates, arranged so as to form a tier of shelves, leaving spaces betwixt in which to place the thin metal plates to be heated by means of steam or other heating media being passed through the said hollow plates; such hollow plates may or may not be enclosed by a casing and doors or otherwise, so as to form an oven. 3, in the employment of a hand press for each piece or fabric by each person engaged in folding and placing the hot plates in the fabrics. *Patent abandoned.*

182. H. B. Barlow. *Certain improvements in jacquard machines.* (A communication.) Dated January 21, 1863.

This invention consists in substituting thin metallic plates for cards usually employed in the jacquard machine. *Patent abandoned.*

183. J. Holt. *Improvements in willowing and opening cotton and other fibrous substances.* Dated January 21, 1863.

This invention consists in admitting steam to the cotton or other fibrous substance during the time that it is being operated upon by the willow or opener. In performing this invention, the patentee makes use of a willow or opener of the ordinary construction, and he introduces a jet of steam between the inside of the casing and the exterior of the drum or beater, or in any other convenient situation. The pipe for supplying is furnished with a tap, which is closed when the door in the casing has been opened to discharge the cotton or other fibrous substances. *Patent completed.*

184. A. Bourée. *Improvements in apparatus for casting or moulding articles in glass, and in imitation of precious stones or marbles.* Dated January 21, 1863.

This invention relates, in the first place, to the manufacture of glass globes for lamps or lanterns, for the purposes of signal lights and other uses, watch glasses, and other articles in glass in which a varied or ornamental surface is required. The invention consists in the construction and use of moulds formed in three or more parts, but by preference in three parts, united by two hinges, such moulds having formed in them perforations of any required number, size, and shape, so that portions of the molten glass when blown into them may be caused to protrude through the perforations and constitute curved projections on the surface of the article, or separate curved glasses when detached from the intervening portions of glass by which they are united in the mould. The invention also consists in the use of an instrument in the form of a vice or pincers, with suitably formed dies inserted in the jaws thereof, in which the molten composition is inserted and pressed, and with a vertical rod or stem, capable of adjustment as to height, in order to make the requisite cavity in certain of the articles by occupying the space that would otherwise be occupied by some of the composition or material. The invention consists further in the use of a mould hinged as stated above, but instead of having perforations with the interior formed to suit the required shape of the articles, they are caused to take their shape by the pressure given to the composition or material by the operation of the workman. *Patent completed.*

185. W. Clark. *Improvements in preparing and obtaining photogenic pictures or representations.* A communication.) Dated January 21, 1863.

This invention relates to a photogenic process, whereby a positive image may be obtained direct from a positive by the employment of ammoniacal salts, combined with the organic matter, and also by the precipitation of the following metallic solutions, viz.:—Salts of silver, copper, iron, nickel, mercury, gold, palladium, platina, lead, or tellurium, which are precipitated by means of hydro-sulphates of ammonia, potash, or soda. The salts of silver, bismuth, or lead are precipitated by means of hydro-sulphuric acid; and the salts of mercury, by hydro-chlorate of tin. The salts of bismuth may also be precipitated by means of nut galls, gallic or tannic acids; and the salts of iron, by means of the same agents last mentioned. The inventor takes, for example, the sulphate of iron precipitated by means of tannic acids. *Patent completed.*

186. W. Clark. *Improvements in desiccating and in preserving matters from decay.* (A communication.) Dated January 21, 1863.

We cannot here give space to the details of this invention. *Patent completed.*

187. E. Bazin. *An improved log.* Dated January 21 1863.

This invention is not described apart from the drawings. *Patent completed.*

188. C. H. Roeckner. *Improvements in machinery and process for reducing wood to a fibrous condition, for the manufacture of paper stuff or pulp.* Dated January 21 1863.

Provisional protection has not been granted for this invention.

189. C. Lindsay. *Improvements in apparatus to be used on railways to indicate to the engine-driver of a carriage train the length of time which has intervened since the passing of a previous train.* Dated January 21, 1863.

For the purposes of this invention, at intervals along e line of railway, apparatus is erected consisting of a pendulum placed in a suitable case, part of which is made transparent, so as to expose such part of the pendulum as may be desired to the view of the engine-driver of a coming train, and so that it may be clearly seen by day and by night, the apparatus being properly lighted at night. A fixed graduated dial is applied to the case, within which the pendulum works, which is also to be exposed to view so as to be seen by the engine-driver of a coming train. The graduated scale and the pendulum are to be of such dimensions, and so arranged that they may be clearly seen at a considerable distance. The pendulum is to be acted on by each passing train, so as to place it to a determined distance beyond its perpendicular position, and then release it, so that it may be allowed to vibrate freely. The length of time which has intervened since a previous train has passed will be indicated (if the pendulum has not come to rest) by the reduced arc in which the pendulum is vibrating as compared with its greatest vibration. The dial is to b graduated to indicate minutes or other determined measure of time. *Patent completed.*

190. A. Pennington. *Improvements in apparatus for beating mats, rugs, and other such like articles.* Dated January 21, 1863.

For the purposes of this invention a rectangular box or

case is employed, of a length and width depending on the sizes of the mats, rugs, or other like articles to be beaten. Near the upper part of this box or case is a partition, by preference horizontal, and made with iron hooping crossed or interlaced, so as to produce a reticulated partition; or the reticulate partition may be made of other suitable material, and in any other convenient manner. Below the horizontal partition is a chamber or bin, in which the dust which is beaten out from the mats, rugs, or other like articles is received, and such dust is from time to time to be removed from the lower chamber or bin, which is made with a door, or is otherwise conveniently arranged to admit of the dust being readily removed from below the reticulate partition. The upper part of the box or case is covered over by a hinged lid, or other suitable cover, below which is a strong canvas or other close-woven or flexible fabric cover, which is by preference arranged to be wound on a roller when out of use. In using this apparatus, the hinged or upper cover or lid is opened or removed, the mat, rug, or other like article is to be placed with its upper surface or face downwards on the reticulate partition, the canvas cover is to be drawn over the mat, rug, or other article, and over the reticulate partition, in order that no dust may be permitted to rise when the mat, rug, or other article is being beaten by a stick, cane, or any other suitable beater. *Patent abandoned.*

191. N. CLAYTON and J. SHUTTLEWORTH. *Improvement in rotary screens, suitable for screening wheat and other grain or seed.* Dated January 21, 1863.

For the purposes of this invention, the patentees make th screening drum of polygonal section, and each side of the polygon they make of two flat metal plates perforated with holes or slits; the plates are perforated to correspond the one with the other, and are placed in contact. One plate of each side the polygon is fixed, and the other is able to slide thereon a short distance, so that it may be set more or less to cover or close the holes or slits in the first plate, and in this manner the gauze of the screen is adjusted as may be required. The sliding plates are by means of springs pressed constantly towards one end of the screen, and they are caused to bear on a moveable ring at the end of the screen; this ring is made with inclines upon it. The ends of the moveable plates have also inclines upon them, corresponding with those on the moveable ring, so that the position of this ring on the end of the screen will regulate the position of the moveable plates. The moveable ring is arranged so that by means of a screw it may be adjusted in position, and firmly held in whatever position it may have been placed. They also make the screen self-cleansing—that is to say, they cause any grain, seed, or other substance which may become jammed in the openings or spaces when the plates are sifting to be released when the plates come in the course of the rotation of the drum to the upper side thereof. To effect this, they mount a friction pulley at the top of the screen, and near one end thereof each of the moveable plates has a projection upon it, and as the screen revolves, these projections come in succession in contact with the stationary pulley, and thus the plates receive a slight motion sufficient to increase the width of the hole or slit, and so let anything which may have become jammed therein to fall out. The springs cause the moveable plates to return to their original position immediately after passing the pulley. *Patent completed.*

192. H. CARO and J. DALE. *Improvements in obtaining colouring matters, which improvements are also applicable to dyeing and printing.* Dated January 21, 1863.

This invention consists—1, in treating colours derived from aniline with the substance known as acroleine, whereby the said colours become modified. Also in treating mauve or aniline purple with aniline and benzoic acid under heat, whereby the tint is modified and a blue colouring matter obtained. *Patent completed.*

193. H. HOLCROFT. *Improved machinery for separating substances of different specific gravities.* Dated January 21, 1863.

This invention relates to a novel construction of automatic machinery, whereby crushed ores or mixtures of granular and other substances supplied thereto may be assorted or separated according to their specific gravities. The machine, which admits of many modifications in its constructive features, is used in conjunction either with a head or stream of water or other fluid, or of compressed air or other gaseous body, according to the nature of the substances to be operated upon. The principle of action, however, of the machine, whatever may be the modifications in the details of its construction, will in all cases be the same, the object being to obtain by the action of a vortex (into which the substances to be assorted are thrown) a separation according to their specific gravities of the substances under treatment, and their deposition in different positions in the vortex vessel, from which they may be discharged automatically into separate receptacles. *Patent completed.*

194. W. HARRISON and B. CROASDALE. *Certain improvements in looms for weaving.* Dated January 22, 1863.

This invention consists—1, in an improved shedding motion. In performing this part of the invention the shedding levers are placed above or in front of the tappet shaft; the eccentrics or tappets acting on these levers give the requisite up-and-down motion to the treadles for forming the shed. The fulcrum of the shedding levers is adjustable to vary the opening of the shed, or the length of the levers can be varied. The second part of the invention consists in an improved arrangement of mechanism applicable to an ordinary twill loom, whereby such a loom may be employed for weaving lenoes or gauze. In performing this part of the invention, the inventors employ four heddles through which the warps are drawn, so that the alternate warp threads are crossed when weaving. They also employ two roller shafts, the rollers on the upper one being connected to two of the heddles by elastic bands or springs. They also employ a rocking vibrator, acted upon by a tappet on a tappet shaft, for slackening a portion of the warp after every two or four picks, or when the crossing takes place. *Patent abandoned.*

195. J. C. BRANDES. *An improved hair creaser or divider.* Dated January 22, 1863.

This invention is not described apart from the drawings. *Patent abandoned.*

196. J. GRANT. *Improvements in the construction of sidings and loop lines for railways or tramways, whether portable or otherwise.* Dated January 22, 1863.

This invention consists, in the first place, in two novel modes of constructing a siding so that it may be placed in position at any part of the main line, and on either side of it, so as to be used for turning carriages out of the main line on to such siding, or from the siding on to the main line, by raising or supporting such trucks or carriages above the rails of the main line, without the necessity for any cuts or gaps through such rails. The invention relates—2, to the combination of a pair of such sidings connected by intermediate rails so as to form a loop line. *Patent completed.*

197. J. ELLACOT. *Improvements applicable to spur-wheels, racks, and other toothed gear, to ensure greater strength in the teeth.* Dated January 22, 1863.

This invention consists in the use of two, three, or more combined teeth placed side by side, and in advance of each other according to the pitch. *Patent abandoned.*

198. J. M. BINGER. *The composition of a kind of pulp proper for the manufacturing of printing and typographical rollers.* Dated January 22, 1863.

This invention relates to an improved paste or pulp for covering the rollers used by letter-press printers to convey the ink or colour to the type, blocks, or plates, and consists in mixing together, in any required proportion, glue, syrup of molasses, gum arabic, rectified spirits of wine, acetic acid, creosote, powdered cloves, and common salt. *Patent completed.*

199. R. PENNEY. *An improved solution or mixture for fixing certain colours employed in printing calico and other fabrics.* Dated January 22, 1863.

This invention relates to the fixing of those colours employed in printing calico and other fabrics which are produced by means of catechu, and usually called catechu colours. For this purpose the patentee employs a solution or mixture made in the following manner, and treats the catechu colour therewith:—He takes of the ordinary chloride of calcium of commerce (which may be made by saturating spirits of salts with quicklime in a powdered state) three, four, five, or other number of parts, and mixes therewith one or other required number of parts of nitrate of copper, at 80 deg., or other required strength, or of chloride or muriate of copper, either instead of nitrate of copper, or in combination therewith; such admixture is to be made whilst the calcium is in a heated state, and then filtered for use. These parts must be varied according to the depth, shade, or tone of colour to be treated. *Patent completed.*

200. W. and J. BLACKWOOD. *Improvements in machinery for drying yarns or threads.* Dated January 22, 1863.

This invention has for its object the convenient and efficient treatment of any kind of yarns or threads when in the hank form. In a modification embodying these improvements, there are two or three cans or hollow cylinders formed with tubular spindles projecting from one end only, and mounted in bearings in such a way that the cans are overhung. The ends of all the spindles are entered into stuffing-box bearings communicating with steam passages, whereby steam is admitted into the cans. The two side cans are made to rotate by means of suitable gearing upon their spindles, but the middle can is turned by the friction of the yarn or thread passing in contact with it. This middle can is also made to put the requisite tension on the yarn, the bearings of its spindle being arranged to allow the can to bear down upon the yarns, and, if its own weight does not give sufficient tension, additional weight may be applied to it. *Patent abandoned.*

201. W. CLARK. *An improvement in piston valves and other pistons.* (A communication.) Dated January 22, 1863.

This invention consists in the construction of a piston valve, or of any piston with an expanding ring, having the head and follower fitted to its interior, and with a dovetail wedge so applied in connection with the ring head and follower as to make the valve or piston as much like a solid block as is desirable, yet capable of being set out to fit the cylinder in which it works and compensate for wear. *Patent completed.*

202. N. WOOD and J. STOCKLEY. *Improvements in apparatus for grinding, smoothing, and polishing plate glass.* Dated January 22, 1863.

This invention consists in constructing and using moveable grinding benches capable of being transported to the apparatus for smoothing and polishing, thereby admitting of one side of the glass being finished in all the processes without the necessity of lifting and relaying the glass in the manner required when the ordinary benches are used. The mechanism applied to the benches for rendering them moveable may be arranged so as to admit of their being transported as required, either throughout the whole series of apparatus for grinding, smoothing, and polishing, or from or to any part thereof. For this purpose the benches are constructed of the usual materials, with a smooth upper surface for the glass to rest upon, and are fitted into a frame provided with wheels or sliding pieces carried upon or in suitable rails or grooves supported on the floor of the shed or shop, upon or in which rails or grooves the benches may be moved in the directions required. There are also combined with the rails or grooves at suitable intervals turn-tables, sidings, or sliding frames, so as to admit of the benches being drawn aside or changed as required. The required progressive motion is imparted to the benches by means of racks and pinions, or other suitable mechanical means. *Patent completed.*

203. T. LAMBERT. *Improvements in apparatus for drawing off water and other fluids.* Dated January 22, 1863.

For the purposes of this invention, in constructing apparatus or taps for drawing off water or other fluids, one end of the barrel is made with a screw or otherwise, suitable to be fixed to a pipe or other source of supply in the ordinary manner. At the other end a suitable valve chamber is formed or applied, the opening into which is covered by a valve, which is preferred to be covered with a suitable yielding and elastic material. Over the valve chamber is a hollow cover which communicates with the valve chamber. This hollow cover has a flange at the end or part where it is connected to the valve chamber of the barrel. The hollow cover is fixed to the valve chamber by a clamping hollow plate through which there is a hole suitable for the passage of the hollow cover. The clamping plate when fixed to the valve chamber or barrel presses on the flange of the hollow cover in such manner as to attach the hollow cover to the valve chamber or barrel, but so as to allow the hollow cover to rotate or turn partly round. The valve spindle or stem is formed with a screw thereon, and the piston is prevented turning in the valve chamber. On the interior of the hollow cover is fixed or formed a screw nut, which works on the screw on the spindle or stem of the valve. The spout or tubular passage through which the water or other liquid is discharged is fixed to or formed on the hollow cover, and is a branch therefrom which serves as a handle to turn the hollow cover, and thus to open and shut the valve. It is not essential that the spindle or stem of the valve should be formed with a complete screw, but such is preferred to be the case, as by its having an inclined thread or groove, so long as the nut carried by the hollow cover is made agreeable thereto, the same lifting and closing of the valve by the turning of the hollow cap will result. *Patent completed.*

204. C. LUNGLEY. *Improvements in means for facilitating the repairs of ships and other structures.* Dated January 22, 1863.

This invention consists in digging or forming pits in the ground, and placing therein caissons with trunks for access and for air. Or the inventor makes the pits water-tight with cement or other materials suitable for the purpose. He fits a campshead of wood or other material, to receive the fittings for making the parts water-tight round the ships or other structures when they are brought over the pits. *Patent abandoned.*

205. F. W. MORLEY. *Improvements in boilers for steam engines, and in valves to be used therewith.* Dated January 22, 1863.

In carrying out this invention, the inventor proposes to make the shell of the boiler of any of the ordinary forms, according as it may be intended for locomotive, marine, or stationary engines, and he applies in lieu of the fire bars at present in use a series of copper tubes, through which the water circulates from the boiler by means of their insertion into the lower part thereof; these tubes therefore will serve the purpose of fire bars, and at the same time communicate heat to the water, which will circulate through them, and ascend to the upper level, while the water of lower degree of temperature will descend to supply the circulation. He proposes to insert a number of fire or hot vapour tubes into the lower half of the boiler, and to insert another series of tubes into the upper half thereof, which tubes are to communicate with the water in the boiler. The valve whereby the supply of steam is regulated to the engine consists of a disc cut with two triangular slots, the disc working reciprocally against the face of a stationary corresponding inlet and exhaust to the cylinder. Motion is given to the disc by means of an eccentric on the shaft of the engine, and the disc being set on a steel pin is always ready to be tightened to its work, so as to prevent leakage by friction consequent from its working. *Patent abandoned.*

206. J. MILNER. *Improvements in steam engines.* Dated January 23, 1863.

The patentee claims the construction of slide valves to two steam cylinders that are in proximity to each other, in which each slide valve not only admits and discharges steam to and from its own cylinder, but also, either by itself, or in combination with one or more passage pieces, serves to cut off the steam entering into the other cylinder. *Patent completed.*

208. E. STRANGMAN. *Improvements in pipes for smoking tobacco.* Dated January 23, 1863.

According to one method of carrying out this invention, the patentee makes the pipe with a moveable thimble, with a flange at the top, and perforated at the bottom, such thimble being placed in the bowl, and intended to contain the tobacco or other vegetable substances to be smoked; and he fills the space between the thimble and the bowl of the pipe with a suitable filtering and absorbent material, so that the smoke in passing from the ignited tobacco to the mouth of the smoker is compelled to pass through the said filtering and absorbent material, and thus becomes purified and deprived of all poisonous and deleterious qualities. *Patent completed.*

209. C. STOFFORD. *Improvements in the construction of hats and other coverings for the head.* Dated January 23, 1863.

In the interior of the hat, or other covering for the head, is placed a band of suitable material, the same being of less depth than the side crown, and attached by the lower part thereof to the interior of the band of the hat or other covering for the head, the upper part of such internal band being left loose and unconnected with the side crown or corresponding portion of the hat or other covering for the head, so as to leave a space between the latter and the internal band for the free passage of air. In order that the air may have free ingress to the space between the side crown and the said internal band, the band of the hat or other covering for the head is perforated or made with apertures therein, such perforations or apertures extending either entirely round the band or only partially round the same. The said perforations or apertures in the band of the hat may be covered and protected externally by a band formed of silk, or other textile material, so woven as to be pervious to the air, and thus allowing it to pass through the perforations or aperatures. At the top of the crown of the hat is an aperture or apertures covered with any pervious material adapted for the passage of the air through the same. *Patent completed.*

210. F. N. GISBORNE. *Improvements in the means of communicating signals on board ship, and of indicating the position of the rudder.* Dated January 23, 1863.

This invention is not described apart from the drawings. *Patent completed.*

211. W. CLARK. *Improvements in mariners' compasses.* (A communication.) Dated January 23, 1863.

This invention relates to the application of electric circuits in an easterly and westerly direction in a ship's compass, in order to compensate for and ascertain the deviation of the needle, as also for finding the direction of the magnetism influencing it. *Patent abandoned.*

212. P. A. COLE. *Improvements in the articles of dress known as collars, cuffs, wristbands, shirt fronts, habit shirts, and petticoats.* Dated January 23, 1863.

Having treated india rubber or gutta percha so as to bring the same to a white state, which the inventor does, for instance, by the use of magnesia, or by the process known as Dr. Cattell's process for purifying india rubber or gutta percha, he stamps or places upon the same lines or dots representing stitching, or devices or ornamentation of any kind. *Patent abandoned.*

213. C. TURNER. *Improvements in the manufacture of felted fabrics.* Dated January 23, 1863.

The object of the present invention is to enable the carrier to take across any desired numer of threads at one time, all parallel to each other throughout, and without any angling near the selvages, and also without there being any accumulation of the threads at the selvages. For this purpose the patentee causes the carrier to traverse to and from side to side of the batt as before, taking with it any desired number of threads, which it lays on the batt at regular distances apart. When the threads come to a selvage, they are, by a brush or otherwise, pressed in amongst pins or points; they are also retained by a blade which descends on to them and nips them; or they are taken by any suitable holding instrument, and in place of being left continuous, as heretofore, they are then cut off, the loose ends of the threads descending from the carrier are also retained in a holder. The batt with the pins or points, or other instruments, are then caused to move forward a distance equal to the width of the sheet of threads taken across by the carrier, and the carrier then returns to the opposite selvage, where the operation of retaining the ends of the threads and cutting them off is repeated, and so the work continues. *Patent completed.*

214. E. T. HUGHES. *Improvements in breech-loading fire-arms.* (A communication.) Dated January 23, 1863.

This invention relates—1, to a novel arrangement of mechanical parts for raising the breech end of the barrel from the breech sufficiciently for the introduction of the charge or cartridge, as well as for closing the same ready for fire; 2, in a mechanical arrangement of parts for forcing the extremity of the barrel in contact with the breech. For the first part of the invention, the inventor unites the barrel to a bed extending from the breech under the said barrel by a joint, and by means of a lever, one part of which is jointed to a tongue protruding from the under side of the barrel, whilst another part is in communication with slots or passages cut in the under part of the breech; he opens the gun to the required extent, and recloses it ready for fire. For the second part of the invention, he makes use of a wedge placed under the barrel, and at right angles with the same, and by means of a screw drawing down the said wedge, he causes the extremity of the barrel to be forced up against the breech. *Patent abandoned.*

215. A. O. GLOSSOP. *Certain improvements in the construction and manufacture of breakfast cruet, liquor, and other frames, or articles, used in dinner and other services.* Dated January 24, 1863.

For the purposes of this invention, glass, porcelain, or other similar substance is used in connection with a metallic or other framework, combined or in separate parts, in such way or manner as may be considered desirable for the formation of the same. By this arrangement, novelty and elegance of design are obtained as well as cheapness. *Patent abandoned.*

216. W. MELLOR and W. WHALEY. *Improvements in steam-hammers and other engines driven by steam.* Dated January 24, 1863.

This invention consists in communicating motion to the slide valves of steam-hammers and other engines driven by steam by means of a screw, which passes through a nut formed in the piston, so that as the piston moves up and down, or to and fro in the cylinder, the screw is turned round in opposite directions. This screw is made of the same piece or attached to another screw acting on a nut connected to the lever to which the valve spindle is jointed. By this means the slide valve is moved to and fro to open and close the steam ports in the valve box. Another part of this invention consists in connecting the valve lever to a rod acted upon by levers and rods for the purpose of varying the position of the fulcrum of the lever, so as to increase or diminish the length and force of the stroke. The invention may be modified by placing the screws to one side of the piston rod; in this case, one of the screw nuts is connected to a projection on the hammer head, and the other is connected to the valve spindle. *Patent completed.*

217. W. ALLEN and W. JOHNSON. *Certain improvements in machinery or apparatus for grinding or pointing the cards employed in carding engines.* Dated January 24, 1863.

This invention is designed to produce taper or needle-like points at the carding extremities of the wires constituting the cards. The ordinary method of grinding cards has been by means of an emery roller, having a hard and even surface or periphery which grinds the cards into the form termed "chisel-edged." These improvements consist in the employment and use of a cylinder or cylinders or rollers having their surfaces or peripheries corrugated or ribbed in a direction across their axis, and coated with emery or other grinding material, a reciprocating motion across the cards, and parallel to the axis of the card roller, being imparted thereto, so that the sides of the grinding corrugations, elevations, or ridges come into contact with the wires, as well as the apex of the ridges, and thus produce taper points upon the cards, which are more efficient in their operation upon the cotton. These elevations, corrugations, or ridges may either be formed helically, that is, coiled around a roller in a spiral course, which is preferred, or they may be composed of a series of rings side by side, and they may consist of india rubber, gutta percha, or other yielding substance coated with emery, or they may be made of wood or other non-elastic substance, but an elastic substance beneath the emery is preferred. *Patent completed.*

218. E. SHACKLETON. *Improvements in looms for weaving.* Dated January 24, 1863.

This invention consists in a means of instantly stopping the rotation of the boxes; also the action of the indicating apparatus when the weft breaks or becomes used up, although the loom may continue to run one or two picks afterwards. For this purpose a drop rod is suspended by the ordinary knocking-off lever when in position or working order, and this rod supports a weighted lever hinged to the loom end in a suitable position. When the weft breaks or becomes used up, the weft fork acts in the usual manner to stop the loom, and by removing the knocking-off lever out of position it allows the rod to drop, and also the weighted lever, which lifts or removes the ordinary hooked rods out of contact with the cylinder of the indicating apparatus, also the pawl out of gear with the ratchet by which it is turned, and also applies a brake to assist in stopping the loom. *Patent abandoned.*

219. E. and G. BOOTH and A. SWALLOW. *Certain improvements in the mode of fixing colouring matter or cotton, silk, wool, and other fibres and materials, and certain improvements in finishing such like and other textile fabrics and yarns.* Dated January 24, 1863.

This invention consists in the use of a solution of spirits of salts, lime, and nitrate of copper, mixed together in certain proportions, according to the depth of colour required, which the inventors use as a substitute for nitrate and acetate of copper and other acids now in general use for fixing catechu and other colouring matters in printing and dyeing processes; and for stiffening and finishing textile fabrics and yarns, they use spirits of salts and a solution of lime mixed in certain proportions, which they apply to the fabrics or yarns in the ordinary manner. *Patent abandoned.*

220. M. A. F. MENNONS. *Improvements in machinery for punching and cutting metals.* (A communication.) Dated January 24, 1863.

This invention is not described apart from the drawings. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated July 16, 1863.

1778. H. Mège, 4, South-street, Finsbury, professor of chemistry. Certain improvements in the mode of treating fatty bodies.

Dated July 21, 1863.

1821. C. H. Roeckner, Richmond-terrace, Clapham-road. Improvements in machinery and process for reducing wood to a fibrous condition for the manufacture of paper stuff or pulp.

Dated July 30, 1863.

1884. J. W. Branford, merchant, March, Cambridgeshire. An improved agricultural implement for hoeing and cleaning the land, and for cutting or setting out the plants of root crops at certain distances from each other.

1889. G. Smith, jun., 230, King's-road, Chelsea, civil engineer. Improvements in buffing and traction apparatus of railway carriages and waggons.

Dated July 31, 1863.

1897. B. Johnson, Church-street, Camberwell-green, pianoforte manufacturer. Improvements in pianofortes.

1899. A. R. Arrott, St. Helen's, Lancaster. Improvements in bleaching certain vegetable fibres used for textile or other purposes, whether in the raw state or manufactured.

Dated August 1, 1863.

1907. T. Bradshaw, Bolton, Lancaster, broker. Certain improvements in machinery or apparatus for giving motion to "Dobby horses," flying and swinging boats, or similar apparatus used for public amusement.

1908. R. E. Bibby, Manchester, Lancaster, drysalter. An improved fireproof cement, which may be employed for covering walls, ceilings, and floors, and is also applicable in the manufacture of fire-bricks, crucibles, retorts, melting pots, and for other purposes where fire-resisting properties are required.

Dated August 3, 1863.

1914. B. W. Gerland, Macclesfield, Cheshire, analytical chemist. Improvements in the manufacture of size, glue, and phosphates.

1915. J. I. P. Bonnet and J. Pfister, 7, Rue Thèvenot, Paris, lamp manufacturers. Improvements in lamps.

Dated August 4, 1863.

1923. J. H. Walsh, Kensington. Improvements in breech-loading firearms, and in the means of extracting cartridge cases therefrom.

Dated August 5, 1863.

1928. E. A. Cowper, 35a, Great George-street, Westminster. Improvements in furnaces for heating air, steam, and other elastic fluids.

1930. G. Wilkins, Birmingham, gunmaker. A new and improved means of railway signalling.

1933. W. Hodson, Hull. Improvements in machinery used for propelling carriages and vessels.

Dated August 6, 1863.

1935. G. Gowland, Liverpool, chronometer maker. Improvements in mariners' compasses.

1936. C. Lowe, Bradford-street, South Bradford, Manchester, manufacturing chemist. Improvements in dyeing and printing.

1939. W. P. Hodgson, Hylton, near Sunderland, and J. V. Woodifield, Hope-street Foundry, Sunderland. Improvements in machinery for the manufacture of rivets.

1941. J. Young, Bucklersbury, gentleman. Improvements in the preservation of animal matter.

1944. G. E. Charageat, 89, Chancery-lane. Improvements in the construction of frames for umbrellas and parasols.

1945. E. E. Quelle, Bermondsey, skin dyer. Improvements in inkstands.

Dated August 7, 1863.

1949. W. Jones, Warrington, engineer. Certain improvements in steam boilers.

1951. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. An improvement in the manufacture of shuttles. (A communication.)

1952. J. W. Slater, Huddersfield, Yorkshire, manufacturer of mordants and colours. Improvements in the production of yellow and orange colouring matters.

1953. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in apparatus for preventing sea sickness. (A communication.)

1954. R. A. Brooman, 166, Fleet-street. Improvements in coke ovens. (A communication.)

1955. E. Watson, King-street, engineer, An improved apparatus, whereby screw propellers may be made to steer as well as propel, applicable also as an improved ball-and-socket joint.

1956. J. Platt, 10, Charlotte-street, Bloomsbury. Improvements in apparatus for supplying steam boilers with water.

1957. T. W. Guillod, 15, Park-place-terrace, Paddington. Improvements in the manufacture of chess boards and chess-men.

1958. E. Morewood, Stratford. Improvements in coating metals.

1959. J. Thompson and E. Gerrard, machinists, and F. A. Fitton, Ardwick, Lancaster. Improvements in engines for carding cotton and other fibrous materials.

Dated August 8, 1863.

1960. N. Jarvie and W. Miller, Glasgow, ropemakers. Improvements in the manufacture of oakum, and in apparatus therefor.

1961. W. B. Robins, Harborne, Stafford, actuary. A new or improved instrument or apparatus for extinguishing fires.

1962. J., T., A., and W. Thornton, Nottingham, manufacturers. Improvements in apparatus used for producing looped fabrics.

1963. A. P. Price, 47, Lincoln's-inn-fields, gentleman. Improvements in the application of india rubber and gutta percha to the manufacture of brushes and mats. (A communication.)

1964. H. R. Brown, Cranbourne-street. New or improved apparatus for the regulated delivery of cards, tickets, labels, bills, and sheets or pieces of cardboard, paper, metal, or other material, for advertising or other purposes.

1965. M. Smith, 71, Fleet-street, preserver. Improvements in obtaining farinaceous material from potatoes.

1966. J. W. Armstrong, Carmarthen, engineer. Improvements in fastening and in securing in position the rails of railways, the said fastening being applicable for other uses.

Dated August 10, 1863.

1969. B. Heyne, jun., Liscard, engineer. Improved apparatus to facilitate sketching and drawing landscapes, buildings, machinery, and other objects in correct perspective.

1970. R. Dickson, engineer, London Wall. Improvements in lithographic printing presses.

1972. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. An improved manufacture of blue and of violet colouring matter. (A communication.)

Dated August 11, 1863.

1973. J. Robson, jun., South Shields, Durham, ironmonger. Improvements in money tills.

1974. E. S. Simon, 13, Bury-street. An improved fastening for leggings.

1976. W. Knowles, cotton spinner, and R. Halliwell, Bolton. Certain improvements in machinery for preparing, spinning, and doubling cotton and other fibrous substances.

1977. D. W. Barker, Anderlecht, near Brussels, Belgium, manufacturer of stuff goods. Improvements in means or apparatus for actuating rotary shuttle boxes.

1978. J. T. King, Liverpool, consulting engineer. Improvements in apparatus for containing and distributing gas for lighting railway carriages, steamboats, and other moveable vehicles and vessels, railway stations, and other places, parts of such apparatus being suitable for governing the supply of gas and air for various purposes.

1979. W. B. Haigh, Oldham, Lancaster, engineer. An improved equilibrium saw frame.

1980. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. An improved process for hardening cast iron. (A communication.)

1981. J. G. Willans, Westbourne Grove Terrace. Improvements in the manufacture of iron.

1982. W. Clark, 53, Chancery-lane, engineer. Improvements in road sweeping machines. (A communication.)

1983. J. Wheeler, 23, Poultry, glove manufacturer. Improvements in the perfuming of gloves.

1984. W. Gray, Brownrigg, Haddington, North Britain, farmer. Improvements in certain parts of reaping machines, and in the working or application of the same.

1985. Sir J. S. Lillie, Knight and Companion of the Most Honourable Military Order of the Bath, 105, Pall Mall. An improved revolving battery.

Dated August 12, 1863.

1986. G. Graham, Manager of the Dalquhurn Turkey-red Dye-works, Dumbarton, North Britain. Improvements relating to baths or boilers used in dyeing.

1987. R. Mushet, Coleford, Gloucestershire, metallurgist. An improvement or improvements in the manufacture of cast steel.

1988. J. Cornforth, manufacturer, and A. Andrews, shoemaker, Birmingham. Improvements in the nails

commonly called screw rivets, which improvements are also applicable to other nails and spikes.

1990. R. Canham, Clerkenwell, foundry manager. Improvements in machines for the preparation of moulds for casting.

1991. J. Templeman, Glasgow, artificial fuel manufacturer. Improvements in the manufacture or production of artificial fuel.

1992. R. S. Newall, Gateshead. An improved mode of, and apparatus for, drying chemical compounds and other substances.

1994. W. Hudson, Burnley, gentleman, C. Catlow, overlooker, and J. Dodgeon, commission agent. Improvements in looms for weaving.

1996. W. Clark, 53, Chancery-lane, engineer. An improved lamp for burning coal oil and other similar hydrocarbons without the aid of a draught chimney. (A communication.)

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated August 14, 1863.

2009. S. R. Wilmot, Brooklyn, United States. Improvements in hand trucks. (A communication.)

Dated August 15, 1863.

2020. P. F. L. B. Hirn, Le Cateau (Nord), France. A waterproof preparation to make fabrics, thread, textile matters, and others impenetrable against water.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, August 25, 1863.

907. T. Baldwin. Superheating steam.
931. M. Myers. Trunks, portmanteaus, and boxes.
935. G. T. Smith. Shutters.
946. W. Clark. Apparatus for the transport of goods. (A communication.)
947. H. A. Bonneville. Gas burners. (A communication.)
949. W. Spence. Manufacture of gunpowder. (A communication.)
950. H. Eaton. Presses for baling.
959. W. Oldfield. Construction of locks.
963. R. Knight. Treating and preparing iron, copper, and other wires.
968. R. H. Lawson and W. Darlow. Obtaining motive power.
970. C. Turner. Manufacture of felted fabrics.
975. W. B. Burden. Locomotive carriages and paddle-wheels.
978. P. G. Rowell and H. Holt. Securing the bands of locomotive engine and tender springs, also a new method of applying the same.
981. C. Blanc. Apparatus for the purpose of using air and steam as motive power.
985. A. Ford and R. Rigg. Reforming and reusing old or waste vulcanized india rubber.
990. M. Runkel. Marine steam engine governors. (A communication.)
992. H., E., S., and J. Yeadon. Healds.
997. W. Ryan and W. Daniel. Transmitting, equalizing, and registering human power.
998. F. E. Bryant. Ascertaining the temperature of steam and its power of tension. (A communication.)
999. T. Settle. Flyers.
1000. F. Durand. Moulding articles of china or other clay, or of other plastic materials.
1006. G. B. Barber. Steam boilers.
1013. P. McGregor. Spinning and doubling.
1015. J. B. Daines. Preparation of stone, plaster compo, iron, wood, and such like substances, so as to preserve them from decay.
1023. J. Thompson. Manufacture of barrels for firearms.
1024. J. Thompson. Machinery for punching metals.
1027. J. H. Johnson. Filtering apparatus for treating by pressure oils, syrups, and all sorts of liquids susceptible of filtering. (A communication.)
1053. F. Bennett. Condensing lead and other metallic fumes and vapours from furnaces.
1067. J. H. Johnson. Preserving property in case of shipwreck. (A communication.)
1089. W. Clark. Manufacture of hydrocyanate of ammonia and of alkaline and earthy cyanides. (A communication.)
1118. E. Chesshire. Intercepting the solid portions of the soil of water-closets.
1135. A. Sturrock. Locomotive engines and tenders.
1254. H. J. Olding. Treating flax and other fibrous plants.
1272. W. Nunn. Construction of signal lanterns or lamps.
1397. W. E. Newton. Construction of casks, barrels, kegs, and other analogous articles. (A communication.)
1445. W. Wells and J. W. Myers. Obtaining artificial light from volatile liquids or fluids.
1464. W. Sims. Compound extract to be employed as a means for the cure of deafness.
1543. T. Smith, T. Moore, and Major Burrell. Construction of reels covered with silk or other suitable material used as machines for the purpose of dressing flour.
1579. S. Robinson, J. Priestley, and J. Foulds. Looms.
1599. D. Hussey. Bobbins and the winding or roving of yarn thereon.
1610. G. Boccius. Manufacture of candles and other like articles.
1630. A. Silvester. Exhibition of dramatic and other like performances.
1640. J. and J. S. Harvey. Cutting tobacco.
1641. T. Taylor. Railway brakes.
1670. J. Oxley. Filtering apparatus.
1691. E. Myers and H. Forbes. Propelling and steering ships.
1710. P. G. B. Westmacott. Cranes and dockgate and other crabs.
1712. P. G. B. Westmacott. Hydraulic presses.
1881. W. E. Newton. Cartridges. (A communication.)
1899. A. R. Arrott. Bleaching certain vegetable fibres.
1915. J. I. P. Bonnett and J. Pfister. Lamps.
1954. R. A. Brooman. Coke ovens. (A communication.)
2009. S. R. Wilmot. Hand trucks. (A communication.)
2020. P. F. L. Bienvaux-Him. Waterproof preparation to make fabrics, thread, textile matters, and others impenetrable against water.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed August 21, 1863.

471. C. Malpas.
473. H. Kilshaw and T. Elce

LONDON, FRIDAY, SEPTEMBER 4, 1863.

HIGH SPEED IN THE NAVY.

THE exploits of the "Florida" and "Alabama" convey too important a lesson to be lightly passed over. They afford an example from which much may be learned, much gained, if we please to profit by the information which their career — almost unexampled in the history of maritime warfare—supplies to the nation and the Government. We have here two steamers of small size, with light guns unprotected by armour, and with crews of, perhaps at most, a couple of hundred men each; doing an unparalleled amount of injury to an enemy's commerce and trade, burning and destroying wherever they please, and setting at defiance the entire Federal navy; fighting when so disposed, flying when occasion requires; intangible, vanishing from the grasp of the destroyer only to destroy. The characteristics of the "Alabama" are well known. The "Florida" is described as a "screw steamer of extraordinary swiftness; her hull long and low; no external traces visible of her real strength and power." It is stated on evidence, which we see at present no reason to doubt, that this little vessel had destroyed not less than 9,700,000 dollars worth of Federal property, up to the 11th of last May, and, most suggestive fact of all, she has managed to elude thirteen Federal cruisers sent specially in pursuit of her. Even if we take these statements *cum grano salis*, the mere fact of the "Florida" and "Alabama" being still in existence proves how difficult it is for regular men-of-war, to capture or destroy vessels whose great speed permits them to act the part of guerillas, the rapidity of whose movements prevents the acquirement of accurate knowledge of their whereabouts. The history of naval warfare shows unmistakeably that heavy frigates and ships of the line are totally unfitted to pursue and capture privateers; just as regular troops usually fail in operations undertaken against men who carry on a predatory, half-savage warfare—half-savage, in that each man acts more or less on his own responsibility, exposes himself to danger as little as possible, and invariably selects those moments when his enemy is off his guard as the best opportunity for making an attack.

In the face of such evidence, we continue to devote all our energies to the production of a magnificent fleet of iron-plated vessels, admirably suited for performing the weightier operations of warfare—ships which may probably add hereafter to the long list of sea battles in which England has been victorious. But we state without hesitation that these are not the vessels to cope with such craft as the "Alabama" and "Florida." The "Warrior" could not waste her time in looking for such ships. True, she might haply fall foul of one of them now and then, sink, burn, and destroy; but we imagine ships of the "Alabama" class would take particular care to keep at that safe distance which prudence dictated from our heavy frigates; and very little examination or inquiry is necessary to show that we have at present no other steam-ships built or building, really competent to undertake the destruction of such dangerous foes to commerce. It is folly to propose the despatch of a frigate costing over half a million sterling in pursuit of a craft not worth the tenth part of the sum: we may rest assured that recourse will never be had to such an expedient while it remains possible to avoid it. What the exact amount of destruction to our commerce may be which would render it impossible, we can form no idea; that it would be very considerable we have no doubt. Thus, in 1812, an American war brig, the "Argus," at one time took up her station off the south coast of Ireland, cruising between the "Tusker" and the "Saltee's," about the 1st of August. "The West India fleet now began to return, the ships of war leaving them at the chops of the Channel, and proceeding to Portsmouth. Now began the 'Argus's' destruction of the homeward-bounds. For several days and nights captures were made, and with their rich and valuable cargoes consigned to the flames, which were seen blazing and smoking as they drifted by. *No large ship of war could be spared at the time* for the Cork station." After doing an incalculable amount of mischief, the "Argus" was destroyed by the "Pelican" sloop of war, sent specially in pursuit of her. We are not a whit better prepared for such foes now than we were in 1812. It is not with gun-brigs we would have to deal in the event of a modern war, but with steamers whose speed would enable them to laugh our ships to scorn; and it is, therefore, well that the attention of those in power should be drawn to the necessity of providing a fleet of small steamers, specially constructed to encounter the privateers—for so we will term them—which a hostile Government would launch by the hundred against our mercantile marine.

The construction of such a fleet would entail little expense. Half-a-dozen serviceable war-steamers might be built, engined, and fitted for the price of the "Warrior;" but to be efficient, they would require to be extremely unlike any of the small sloops or despatch vessels we have now afloat. The first consideration must be speed. On this their powers of attack, their capabilities for making reprisals, and the facility for escaping when threatened by an overwhelming force, would entirely depend. Length would be necessary to ensure velocity; light draught of water to enable them to pursue, or fly, into shallows; a qualification which would seem to dictate a recourse to the twin-screw principle, or something analagous.

To cover such vessels with armour plates would be simply to render them useless. As a rule, they would have to contend only with ships as unprotected as themselves. They would no more attempt to encounter a modern frigate, than one of our 10-gun brigs of 50 years ago would a 120-gun ship. It might, probably, be found advantageous to fit them with a single strake of armour plates between wind and water; even this is doubtful, and should only be done after mature consideration. The question of armament is not one difficult of solution. A single 100 lb. rifled gun on Whitworth's, or some other principle equally good, and a couple of 68 lb. muzzle-loaders, would, we conceive, be amply sufficient. Did we possess any large guns perfectly trustworthy, they could find no place more suitable for the exercise of their powers than on the upper decks of such ships. The evils attending the discharge of the heaviest ordnance between decks, in comparatively confined situations, is well understood. In the open air, however, and with plenty of room to work them, their use would quickly become as habitual to the sailor as the carronade or the long 68; but, unfortunately, the success of any gun throwing shot over 100 lb. weight is too exceptional to enable us to calculate with certainty on their capabilities.

Masts and sails would, we conceive, be out of place in the ships we speak of. Depending wholly on their engines for the excessive speed which would really be the measure of their efficiency, spars would be of little service; and, being liable to be shot away, might foul the screw at the most critical moment. They are inimical to the attainment of speed, unless when going dead before the wind, or nearly so. It is very well understood that the top hamper of our steam frigates is a principal cause why they do not attain the speed of our merchant vessels; and ships intended to steam 17 or 18 knots an hour could not tolerate their retarding influence. It is generally considered that a steamer without spars would be powerless if her engines broke down. Perhaps; but there is no reason whatever that when placed in such a predicament she should not resort to the same expedient as a sailing vessel which had lost her masts—nothing would be easier than to stow jury masts, &c., so that they could be rendered available when occasion required. The absence of masts and top hamper would render a steamer burning Welsh coal, almost invisible at the distance of a few miles; one of the most desirable objects in the kind of warfare we are speaking of.

When we remember how light the armament necessary to these vessels would be, it is easy to understand that great size would be out of place. The real measure of their carrying capacity would depend on the size of their engines, and the quantity of coals stowed. 17 to 18 knots could be got in fair weather from vessels propelled by engines of some 3,000 effective horse-power. 800-horse power has been developed ere now by a 35 ton locomotive; and there is no reason that marine engines should be much heavier proportionately to their power. Screw engines and boilers, with water, of 3,000-horse power might, by a liberal use of steel, and wrought iron instead of cast, be so constructed as not to weigh more than 200 tons. Making every allowance, 70 tons of coal in the 24 hours would supply the engines with steam; and a cruise of eight days, nearly at full speed, would thus come within the powers of the ship. The mere fact, however, of a ship being able to steam 17 or 18 knots an hour, is no reason whatever that she should always run at that speed. The consumption of fuel increases as the cube of the velocity, and a very slight reduction in the number of knots steamed per hour would enable coal to be reserved for those moments when the engines would be exerted to the utmost. A powerful blower, arranged suitably, would double the evaporative power of the boiler at such a time. The mechanical engineer would experience no difficulty in constructing engines which, while very light, would be extremely trustworthy. Although run occasionally at the high speed for which they should be specially designed, their ordinary rate would be moderate, consequently repairs would not be heavy; and not only the engines but the ships could be refitted in almost any port on our coasts, as their moderate size would place them within the powers of any private ship-building establishment or engineering firm.

These war vessels would be admirably adapted, as well to afford a secondary protection to our own commerce as to destroy that of the enemy, while their comparatively trifling cost would deprive the loss of one or two, now and then, of any very serious consequences. We have not at present a single ship of the kind. The old steam-frigates of the "Bull-dog" and "Cyclops" class are fast disappearing, their slow speed rendering them utterly worthless. The all-absorbing subject of iron-plating has thrown every other question connected with

the Navy or the protection of our commerce comparatively into the shade, and our naval establishment will soon be composed of nothing but costly first-rates. That the construction of heavy war ships is of importance we admit; but that it is of an importance great enough to banish all other considerations we deny. A "Florida" or an "Alabama" may play havoc with our commerce to-morrow; and we feel pretty certain that our iron-plated frigates will be far too busily engaged to prevent them. The Government may, perhaps, contemplate taking up and arming our merchant steamers in the event of a war. The evidence given before the House of Commons some 14 or 15 years ago, was scarcely sufficiently encouraging even then to warrant any great reliance on the aid to be derived from such a force; there is not a ship of the kind which would not require immense strengthening before she could be considered fit to carry one or two 68-pounders, and war might be half-over before they could be qualified to take any part in it. To be at peace, let us be prepared for every description of naval attack and defence. A few hundred thousand pounds, properly laid out now, may possibly prevent the loss of millions hereafter; and our readers may rest assured that the question we have placed before them is one of vital importance, well worthy the careful study of thinking men.

LOCOMOTIVE IMPROVEMENT.

The locomotive engine appears to have arrived, two or three years ago, at that point in its history where improvement ceased, at least, for a time. There is nothing remarkable in such a fact, which is common to every description of machinery. Any one who will take the trouble to compare Stephenson's "Rocket," now preserved in fair order at the South Kensington Patent Museum, with the engines of the "Planet" class, one or two of which have been treasured up by the North-Western Railway Company; and these, again, with the engines of the long-boiler variety, with outside cylinders and forked connecting rods, many of which are still working—will see how great has been the march of improvement which has developed the magnificent machines exhibited last year, from such imperfect examples of engineering skill. It is not at all strange that we should rest content for a time with what has been accomplished within the last thirty years; but it would be very erroneous to conclude that this pause is likely to last, or that it arises because the locomotive holds out no inducement to the engineer to exert himself further in developing its powers, increasing its economy, or adding to its durability and efficiency. There is a certain point in the progress of every machine when it performs its duties so well, that any attempt at further improvement holds out little prospect of pecuniary reward; inventors pass it by then, turning their attention to something which more obviously requires the exertion of their peculiar talent. The locomotive is pre-eminently a machine of this class, being really so far perfected that nothing but the refinement of mechanical skill can add to its merits. The reward for such improvements may not be great to the inventor, but they cannot fail to be to railway companies; and although there is no great field for outsiders, there is for locomotive superintendents and others, who have it in their power to introduce those little matters of detail, which, seemingly very trifling, really conduce in a superlative degree to the efficiency of the machine.

The introduction of good coal as a substitute for coke has become almost universal on all the railroads in Great Britain, the saving effected being very considerable, amounting to many thousands per annum on such lines as the North-Western. All things considered, the production of smoke from coal-burning engines is not very great, and with a little more care might possibly be reduced to half what it is at present. Even now, however, it can scarcely be considered a nuisance, except by the fastidious. With a roomy fire-box, and a free admission of air above the fire, almost any coal can be burned without smoke. It is not easy to secure these conditions, however, in the locomotive. The furnace doors are far too small to supply all the air required if perforated ever so closely on Wye Williams' principle; and their fire-boxes are too confined to permit flame to exist in them as freely as it ought. Theoretically the gases should remain in the box till consumed, a condition impossible to secure completely. The scoop deflector has been introduced as a substitute for the perforated fire-door, and the brick fire-bridge to detain the gases and aid their combustion. These, combined with a long grate and a deep fire-box, give better practical results than can be derived from the use of the combustion chamber, which is rapidly going out of favour. The employment of this expedient — to designate it by its proper name—entails a shortening of the tubes, which is fatal to economy, and materially hastens the destruction of the smoke-box and stack. An increase in their number, and reduction in their size, as practised at one time on the East Lancashire line, where 427 tubes of 1¼ in. diameter were crowded into a shell of but 3 ft. 8½ in. outside diameter, has given anything but good results, either in the economy of fuel or the durability of the boiler. Mr. Williams and many others have endeavoured, ere now, to prove that length of tube was superfluous, inasmuch as experiments showed, that evaporation was almost wholly confined to that portion of the tube surface next to the fire-box. Most of these experiments were made with model boilers, employing gas jets to produce the necessary heat. The results obtained were fallacious. We have every reason to believe that a locomotive boiler with 2-in. tubes evaporates a very considerable quantity of water close to the smoke-box when travelling at a high speed. It is taken for granted that flame will not enter a 2-in. flue for any considerable distance; this is perfectly true with a moderate draught. When the fire is urged, however, by the powerful action of the blast-pipe at high speed, such flues become filled with flame from one end to the other if not more than 8 or 9 feet long. Any engineer can determine the fact for himself by drilling a few sight holes in the smoke-box door. It is well known that by exposing a Davy lamp to a strong current of air, flame will be forced through the wire gauze, and accidents have ensued ere now from this cause. Flame will not enter small tubes from precisely the same reason that it will not pass the gauze meshes of the lamp; but the opposing force can be overcome without difficulty, and nothing is easier than to compel flame to enter and traverse a tube of moderate diameter. How much smoke may be consumed (to popularize the action which takes place) within the flues of a locomotive boiler, is a subject well worthy of careful inquiry. Large and long flues may, after all, be quite competent, when aided by a roomy fire-box, to supply all the space necessary for tolerably perfect combustion, without entailing any of the difficulties which beset the combustion chamber, and as experience proves without any risk of wasting fuel; for more heat is lost in permitting the escape of unconsumed gases through small flues, than can possibly follow from the use of large flues, which, although they offer less heating surface, yet render that surface more valuable by permitting the existence of flame within them.

Though locomotives consume the products of combustion moderately well, we have no reason to conclude that their efficiency, or the economy of fuel burned, is as yet anything like what it should be. The average evaporative duty of the locomotive boiler does not much exceed 8 lb. of water converted into steam, for each pound of coal put into the fire-box. Lord Dundonald succeeded, years ago, in evaporating nearly 13 lb. of water, for each pound of coal consumed, in a marine boiler not of the best type—a result generally attributed to slow combustion. Experiments conducted in France, however, fail to confirm such a conclusion, as the employment of a forced draught, with quick combustion, was proved beyond dispute to add equally to the efficiency and economy of a boiler properly constructed, though not specially intended for the employment of the principle. The straight sides of the locomotive fire-box—or, worse still, those which are wider at the top than at the grate—are extremely unsuitable for communicating heat to the water surrounding them. A vertical surface is certainly not more than half as efficient as one steeply inclined over the fire, a film of steam remaining continuously in contact with the plate, and preventing that absolute contact of the water with it which is essential to the rapid production of steam. Mr. Sinclair, of Glasgow, constructed the fire-boxes of some of his small locomotives with inclined sides with the greatest advantage, and the principle deserves general adoption. It reduces the size of the tube-plate, however, so much, that in order to carry it out as it should be, grates must be made much wider than they now are—a difficult job on the narrow gauge, from the position of the trailing and driving wheels. Anthracite coal-burning engines have been successfully constructed in America with grates 7 ft. wide across the track, and as much as 6 ft. long. Were such enormous grates adopted here, it might be found advantageous to cover them round the sides with fire-bricks, which would protect the plates and conduce materially to the regular production of steam. A thinner fire, too, might be maintained on the grate with manifest advantage, as far as the prevention of smoke is concerned.

The feed-pump is rapidly being displaced by the injector. On the North-Western it is only retained on a few old-fashioned engines, as much, perhaps, for the purpose of comparison as from any other reason. A feed-pump, filled with air-vessels and all the requirements necessary to hydraulic machinery, driven at a high speed, is really rather a complicated piece of machinery, easily put out of order, and exposed to risk from frost, &c. We understand that on the Eastern Counties line, where the application of the injector is all but universal, a very considerable saving is effected in the item of feed-pipes alone. Not one has ever burst when the injector is employed, while with feed-pumps of the best construction they were continually being ruptured, either by the irregular action of the pump or by frost. The engines, too, are found to keep their steam better when running, if the boiler is fed by the injector than when supplied by a pump. There is little doubt that the expenditure of steam is far greater with the former for equal quantities of water fed in than with the latter; but this really is a matter of very little consequence when we consider the advantages held out by the injector. The simplicity of its arrangements, the ease with which it can be fitted

and, we may add, the certainty of its action under all the varying circumstances to which a locomotive is exposed, render its application one of the most important improvements the locomotive has received of late years.

BRITISH ASSOCIATION.

Mechanical Section.

AIR-ENGINES AND AIR-COMPRESSING APPARATUS.

Mr. J. Jameson, Close Engine Works, read a Paper on "Air Engines and Air-compressing Apparatus" in which he pointed out that in the steam-engine not more than one-seventh of the total consumption of heat was utilized, and then proceeded to enumerate the causes of the non-success of the air-engines which have hitherto appeared, referring to two as types of the whole. In the first, he showed that, in addition to the heat required to work the engine, there was a consumption of heat in the hot chambers of the generators, resulting only in the development of heat in the cold chamber, which actually resisted the action of the engine; that this absorption and development of heat acted in three ways—first, in absorption, by diminishing the working pressure; next, in its development increasing the resistance; and, thirdly, in interfering with the action of the respirator. He also stated that the necessity existing for keeping all parts of the machine at once in motion resulted in a loss of effect, represented by two to four cubic feet for every foot of air contained in the working cylinder at the best point of the stroke, and he said that the operation of these causes necessitated the employment of excessive heat or very low speed, an almost fatal alternative. The second type of air-engine, he said, required the employment of extremely large apparatus, because there was a pressure diagram and a resistance diagram caused by the working of a pump, and the total diagram must always, therefore, amount to three times the effective diagram. In the air-compressing apparatus he described that the defects he referred to were obviated by the fact that there is no transference of heat from the hot to the cold chambers, but that the total heat absorbed in the hot chamber was converted into mechanical effect, and, therefore, a lower degree of heat might be employed; that there is no difficulty in the arrangement from cushioning in the working cylinder; that the highest point of pressure obtained in the generator is not again lost, as it is in all other cases; and that, in addition to the improvements effected on the first type of engine he described, the new apparatus is capable of receiving the whole effect obtainable by the use of the second form of apparatus, and without its resistance, and at high instead of low pressures. He finally referred to the advantages to be derived from the use of air instead of steam, which he stated to be a saving of fuel; freedom from risk of explosion, bursting under air pressure being comparatively harmless if it should occur; but he stated that no safety-valves were required in the apparatus decribed by him, as it was self-governing in the production of pressure: it was not liable to disarrangement—would work reversed as well as forward. Insurance was not affected by the use of the engine, and the compressed air might be applied in any situation, be laid on like gas, to be used when and how it was required. He stated that power might be applied in this way to a whole town, at a cost infinitely less than the cost of the present method, and with other advantages which required no comment.

Mr. Siemens said that the use of four generators was a disadvantage, resulting in four losses of heat; that he apprehended the curves of the diagram exhibited did not follow the law of the dynamical theory of heat; that the effect of cushioning was an obstacle that Mr. Jameson did not appear to allow for; that the loss of effect by cooling was considerable; and that he apprehended the necessity of a full red-heat to produce the effects described, and the more so because the heat in the cold chamber required a double heat in the hot chamber to compensate for it.

Mr. Jameson replied that four generators were only drawn for illustration of the principle, but, practically, he in no case used more than two. That the point of the curves bearing upon the question at issue were the end points, and unaffected, so far as the illustration went, by Mariott's law; that the case referred to was change of temperature amounting to 500 degrees, in which 20 degrees were allowed for cushion. But that cushion did not exist in the apparatus he had described except in an infinitely mall degree, and, consequently, a heat much below ed was required to produce a double expansion; that the cooling effect referred to by Mr. Siemens was an effect for which waste heat would entirely compensate, as it occurred in a part of the apparatus quite separated from the generators; and that, as far as the effect of heating in the cold chamber was concerned, the apparatus possessed the important advantage, by means of double valves, of enabling the air passing from one generator to another to be cooled, whereby the cold chamber remained in an efficient state at all times.

A Member said he had been working once with the the inventor of the moderateur lamp, Mons. Blanche, at an apparatus for a similar purpose, and they found a disappearance of pressure of a very remarkable character. He also apprehended great inconvenience from the introduction of a reservoir, as all empty space in air-engines was most injurious.

Mr. Jameson said that he had not found any disappearance of pressure for which he could not account by defective joints, and, by a peculiar construction of joint, he was able almost entirely to prevent leakage; and also explained that the reservoir he had introduced being separated from the generators by a valve which only opened when the generator pressure exceeded the reservoir pressure, entirely prevented any injurious effects from arising in the way indicated.

Prof. Pole, F.R.S., said he would be glad to hear of some results.

Mr. Norman Cookson, Newcastle, explained that several engines had been built, one of which, indicating 3½ horse-power, could be maintained in action for 10 hours with 70 lb. of coal; that a smaller one of half that indicated power required nearly the same quantity of coal, simply because the fire could not be kept alight with much less.

Mr. Spencer said Mr. Jameson had modestly stated the consumption of heat in steam-engines to be seven times the effect. He might have said fourteen times. He was very glad to see an effort to convert heat directly into mechanical effect. He hoped it would be persevered in, and had no doubt there would be a result.

[We understand the engines selected by Mr. Jameson as the types of the whole were those mentioned the previous evening by Sir Wm. Armstrong.]

REGENERATIVE GAS-FURNACES.

Mr. C. W. Siemens read the following Paper on these ingenious pieces of machinery:—

The principle of the regenerative gas furnaces has already been explained to the scientific public, by Professor Faraday, in a lecture delivered by him at the Royal Institution in June, 1862. Its general construction and the history of its invention and gradual development form, moreover, the subject of a Paper which was read by me in January, 1862, before the Institution of Mechanical Engineers. Since that period this principle of heating has been extensively applied in England, France, Germany, and other countries to glass-houses, for heating gas retorts and muffles for metallurgical purposes, for melting steel, and for puddling and welding iron. The ostensible object of this invention being to save fuel, it could hardly be expected that it would be favourably looked upon in this, the greatest coal-producing district of the whole world; but experience has proved that there are other advantages resulting from its application which, in the case of puddling and working iron, are even superior in value to mere saving of fuel in a money point of view. A diagram was exhibited representing a furnace for welding and working iron, and the gas-generator connected with it. The heated chamber is of the usual form, but instead of a fireplace there are four passages (two at each end of the chamber) leading downwards into four regenerators or chambers filled with loosely piled fire-bricks. The lower extremities of these four regenerator chambers communicate with two cast-iron reversing valves. The gas arriving from the producer through a pipe is directed by the valve into one regenerator or other according to the position of the valve. The gas then ascends through the one regenerator, where it takes up the heat previously deposited in the brickwork, and issues into the furnace at a point where it meets with a current of heated air arising from the second regenerator to effect its combustion. The products of combustion pass away through the opposite regenerator and the reversing valves into the chimney flue. The last-named regenerators receive at this time the waste heat of the furnace, heated at their upper extremity to the temperature nearly of the furnace itself, but remaining comparatively cool towards the bottom. Every hour or half-hour the direction of the currents is reversed by a change of the valve lever, the heat before deposited in the one pair of regenerators is now communicated to the air and gas coming in, while the waste heat replenishes the second pair of regenerators. The gas producer consists of two inclined planes upon which the fuel descends, being gradually deprived in heating of its gaseous constituents, and finally burnt to carbonic oxide by the air entering through the grate at the bottom of the inclines. Water admitted at the bottom also assists in the decomposition of the ignited coke at the bottom, converting the same into carbonic oxide and hydrogen gas. The saving of fuel which has been effected by this arrangement amounts to from 40 to 50 per cent. In the application to reheating and puddling furnaces a saving of iron has been effected, owing to the mildness of the gas flame, of from 3 to 4 per cent. of the entire quantity put in; the iron also welds more perfectly than it does in the ordinary furnaces. Smoke is entirely obviated. By another arrangement the regenerative principle has been applied also to coke ovens, the result being that the separation of the coke from its gaseous constituents is effected without losing the latter. In placing the coke ovens, constructed on this plan, near the works where the iron is puddled and reheated, the latter operation may be entirely effected by the gas generated in producing the coke necessary for the blast furnace in producing the pig iron. The gas resulting from the regenerative coke oven may be used to heat the blast, and boilers connected with the blast furnace. These latter improvements are now in course of being carried into effect on a large scale. The gas produced from the last-named producers is of a very illuminating character, and may, it is repeated, be used for that purpose in preference to the hydrocarbon now manufactured for that purpose by a much more expensive process.

RICHARDS' STEAM INDICATOR.

Mr. C. T. Porter, London, read an excellent Paper on "Richards' Indicator for Steam Engines." He had much pleasure in announcing that arrangements had been made at Messrs. R. Stephenson and Co.'s by which one of these indicators would be in use upon their engine during the meeting of the Association, where it might be seen in operation from 2 until 6 o'clock each day of the meeting. A model of the instrument and diagrams illustrated the contents of the Paper.—A vote of thanks was carried to Mr. Porter for his excellent Paper.

Mr. Thompson, Belfast, was of opinion that this indicator was evidently a step in the right direction.

Mr. Oldham, of Hull, inquired what was the difference of price of this instrument as compared with the ordinary one. He saw that it was made by Elliott, of London.

Mr. Porter said it was. The price was £8 10s. As compared with the smaller cylinders made by other well-known makers, the price of this instrument was rather higher, but not so high as those for the same area of cylinder. The Messrs. Elliott had calculated not to manufacture any instrument smaller than half of a square inch. They would, however, receive special orders for special instruments.

Mr. Robert Mallett, C.E., London, said he had seen the indicator in use in the Great Exhibition at London, where it was applied by Mr. Porter to his own engine. Nothing could exceed the beauty of its action when indicating a high-pressure engine when working at a speed of 600 or 700 ft. a minute.

Mr. John Fernie, Derby, spoke in terms of commendation of the instrument, which he had seen in use both in the Exhibition and also at Messrs. Stephenson's.

Mr. J. F. Spencer, Newcastle, referred to the ordinary form of indicator, pointing out its defects, which this instrument remedied.

IRON SHIPBUILDING.

Mr. C. M. Palmer, of the Jarrow Works, read a long and elaborate Paper on "Iron Ship Building." After a few preliminary observations Mr. Palmer said:—

The principal advantages claimed for ships of iron, as compared with vessels of timber, are briefly these:—In vessels of 1,000 tons the iron-ship will weigh 35 per cent. less than the timber vessel, the displacement of water being the same. The iron ship will, therefore, carry more weight, and, as the sides are only about one-half of the thickness, there will, consequently, be more space for cargo. The additional strength obtainable, too, allows iron ships to be built much longer and with finer lines, thus ensuring higher sailing or steaming qualities, with greater carrying power,

and, therefore, greater commercial results. In wooden vessels repairs of ruinous extent are frequently required, while the repairs in iron ships are generally of a lighter character, and are only needed at long intervals. An iron ship is not liable to strain in a heavy sea, whereas the straining of a timber vessel often damages a valuable cargo. The bilges of an iron ship can be kept clean and free from the disease-engendering bilge-water which is always found in a wooden ship. Moreover, the use of iron masts, steel yards, and wire rigging effects a very large saving of weight, and affords the greatest facilities for the application of patent reefing sails, and other appliances, by which economy of labour is attained, and many risks of loss of human life avoided. As to the form of building iron ships, and the manner of combining the iron so as to obtain the requisite amount of strength with the least amount of material, much difference of opinion exists among practical men. The angle iron frame and plating of the iron vessel take respectively the places of the timbers and planking of the wooden ship; and it has been found by experience that plating one-eighth of an inch thick is equivalent in effect to planking of oak one inch thick, while plating 11-16ths of an inch thick is equal to planking of oak 5 in. thick. As in the largest American wooden vessels, the plank is seldom more than 5 in. inches thick, so it may be argued on the above data that the plating of the largest iron ship need not be more than 11-16ths thick; and any strength required above that which such plating would give should be obtained by means of framework. Many practical men, however, advocate the system of light framework, and, in order to obtain the measure of strength necessary, the application of thicker plates. That the principle of strong framing and plating of moderate thickness is most advantageous may be shown by many facts other than those which are derived from the most modern practice of wood shipbuilding. The strength of an iron ship, as in a girder, depends on its capability to resist the buckling and tensile strains that it is called on to bear. But I believe that we have, in reality, only to make a ship strong enough to resist the buckling strain; and I am led to this conclusion by experiments conducted for that celebrated work, the Britannia Bridge, which proved that in constructions of wrought iron the resistance to the tensile strain is much greater than their resistance to buckle, and, in consequence, the upper part of the girders are made much stronger than the lower part. We have, in my opinion, to make the parts of an iron ship, in principle, like a girder. A girder, however, is at rest, and the strains are always in some known direction; but in a ship, the position of which is ever varying, it requires to be so conducted as to resist the strains in such varied positions. If the side of a ship could remain as in a girder, constantly vertical, then the advocates for the thick plates and small frames might be able to show that their system was the most economical way to obtain the requisite strength; but, as such side, if laid over, as it is in a ship at sea, would, without support, bend or buckle of its own weight, it is evident that the framing is absolutely necessary to keep the plating firm in position, and consequently the strength of the ship depends in a very great degree on the strength of the framing. Another fact that shows the economy of strong frames is that a plate, with a piece of angle iron attached to its edge, would bear much more before buckling than a similar plate increased in thickness so as to weigh the same as the plate and the angle iron. But the great and most important argument in favour of moderately thick plates and strong framing is that all the work must be put together by hand; for, though many attempts have been made to rivet ships by machinery, none seem yet to have been successful even in a mechanical point of view. So soon, therefore, as the thickness of plates and the size of the rivets pass the point at which the workman with ordinary exertion can accomplish good work, then the attachment of the parts by means of rivetting is subject to the risks of imperfect workmanship. It is, therefore, my opinion, both in a practical and theoretical point of view, that we ought not to use plating in any vessel, however large, more than about three-quarters of an inch in thickness.

Mr. Palmer next gave some account of iron shipbuilding in the Tyne, Wear, and Tees from 1842, when the first iron steamer—the "Prince Albert" —left the Walker slipway, to the present time. The competition of the railways in the carriage of coals gave the first great impetus to the building of screw colliers; and from 1852, when they first began to be employed in this trade, 5,212,713 tons of coal have been carried to London by them. Since its first introduction, too, the screw collier has been greatly improved, and the facilities for loading and discharging very largely augmented. The screw collier "James Dixon" frequently receives 1,200 tons of coal in four hours, makes her passage to London in 32 hours, there, by means of the hydraulic machinery which the President invented, among the other inventions which distinguish his name, discharges her cargo in 10 hours, returns in 32 hours, and thus completes her voyage in 76 hours. The "James Dixon" made 57 voyages to London in one year, and in that year delivered 62,842 tons of coal, and this with a crew of only 21 persons. To accomplish this work on the old system, with sailing colliers, would have required 16 ships and 144 hands to man them. Proceeding to the subject of iron ships of war, Mr. Palmer said :—

The first iron vessel for war purposes constructed in this district was the "Terror," one of the large iron-case floating batteries designed during the Russian war to operate against Cronstadt. This vessel, of 2,000 tons, 250-horse power, carrying 26 68-pounder guns, was built in three and a-half months, and she would have been completed in three months had not the declaration of peace slackened the energies of our men, which, up to that time, had been maintained so nobly by their patriotic feelings. It was in the building of this vessel that rolled armour plates were first used. The demand for forged armour plates was so great that the forges of the kingdom could not supply it, and recourse to rolling was unavoidable. At the time the largest plate mill was at Parkgate; and we accordingly employed Messrs. Beale and Co., the owners of Parkgate Works, to roll the plates we required. To the use of these rolled plates, however, the Admiralty opposed itself; but we feeling convinced, by experiments which we made, that the rolled armour plates were at least equal to the forged, invited the Admiralty to a trial of their efficiency. We built a target 9 ft. square, on a plan which we thought might be advantageously adopted for large vessels of war, and on the cellular principle. The cells we filled with compressed cotton, which we had found by experiment to be very effectual in stopping shot. On this target was a thin teak backing, and on the teak were bolted one hammered and two rolled plates. The target was bolted on to the side of an old wooden frigate at Portsmouth, under the direction of Capt. Hewlett. The first shot fired at it missed the target, went through both sides of the frigate, and, to my great astonishment, skimmed over the surface of the water for nearly a mile. The firing showed that while the hammered plate split and cracked to pieces, the rolled plates were not broken—only indented—and were superior to the hammered plate in every respect. Unfortunately the target was not firmly bolted to the vessel, and it sprung at each shot, so that the bolts which held the armour plates were broken, and they fell into the sea. A shot was then tried to test the resisting power of the compressed cotton, and it appeared to answer so well, that Captain Hewlett advised a series of experiments to be tried. The Admiralty were willing, but required us to provide the targets at our own expense. Having already spent upwards of £1,000 on experiments for the good of the country, we declined this proposal; nevertheless, we had proved to the Admiralty this important fact—that the rolled plates were superior to the forged, and they have since been universally adopted. We claim, therefore, for this district the honour of being the first to prove the strength and utility of rolled armour plates, since known and spoken of in Parliament as "Palmer's rolled plates."

Having expressed his opinion that the "Defence," built in his yard, did not from her peculiar model combine all the strength which might have been obtained with the same weight of material, and given a few details of the extent of his own works as a sample of the development of our manufactories, Mr. Palmer, in conclusion, said :—

A consideration of the future of the iron shipbuilding trade opens out a vast field for speculation; but the ultimate result is not difficult to anticipate. We have seen with what success sailing vessels have been superseded by steamers in the coasting and coaling trade, and we know that magnificent fleets of steamers engaged in the postal and other services are ploughing almost every known sea. As commerce increases there will be few trades in which the employment of iron steamers will not be found of advantage. Most of the carrying trade to the Baltic and Mediterranean is already conducted in vessels of that class, and the sailing ships that cross the North Atlantic are being rapidly displaced by iron steamers. Their advantages in strength, speed, and capacity are so marked that sailing vessels of timber must give way before them. Even the Admiralty, cautious and unyielding though it be, will have to abandon its "wooden walls" in favour of the stronger and more useful material—a material, too, that lies in rich profusion beneath our feet, and has not, like timber, to be purchased of other nations. The commercial men of this country have set the Admiralty a signal example of industry and enterprise. It is they who have made the experiments and adopted the inventions that have established the maritime supremacy of this country; and it is owing to their energy that we find on every sea, in the shallow rivers of the East, and the deep, broad waters of the West, English-built ships of commerce diffusing the benefits of free trade, and linking nations and tribes together in the bonds of amity and peace. The true source of our national greatness is to be sought in this wonderful development of our merchant navy. Other nations are entering into friendly rivalry with us; but the larger share of the carrying trade of the world will ever be secured to that country that can produce vessels combining the largest capacity with the utmost amount of economy and expedition in construction, and that can, at the same time, navigate those vessels with the greatest degree of skill and rapidity. The mineral wealth of this district, and the skill and endurance of its workmen, whether on land or sea, will, I feel convinced, enable the locality that gave birth to an Armstrong and a Stephenson to maintain its character for maritime industry and enterprise, and bear its full share in promoting the commercial greatness of the country.

DEPOSIT IN BLAST FURNACES.

Mr. J. Pattinson read a short Paper on a deposit found in the waste gas tubes of blast furnaces smelting Cleveland ironstone. It was as follows :—

A substance, in fine powder, varying in colour from blackish grey to almost white, is deposited in the large tubes used for conveying the waste gases of iron smelting furnaces to the boilers and heating stoves, where they are economized. Some of the constituents of this deposit are doubtless volatilized by the intense heat of the furnace, whilst others are merely carried over mechanically by the current of the gases. In the waste-gas tubes of the furnaces in which Cleveland ironstone is smelted, this deposit accumulates in such quantity as to necessitate the cleaning out of the tubes every three or four months. It also adheres to the bottoms of the boilers and to the heating stove pipes, from which it has to be occasionally removed, as it materially prevents the conduction of heat. So far as I am aware, no analysis of this substance has yet been published. It appeared to me that such an analysis would be interesting, as pointing out the nature of the substances volatilized in such quantity by the action of the blast furnace. The sample selected for analysis was obtained from the waste-gas tube of a furnace belonging to Messrs. Gilkes, Wilson, Pease, and Co., of Middlesbro'. In order to avoid as much as possible the presence of particles of dust carried over mechanically, the sample was taken from under the side of the tube, at a point distant about 140 ft. from the furnace. A mixture of Upleatham and Rosedale ironstones, with Weardale blue limestone and South Durham cokes, had been smelted in the furnace for some considerable time previous. The deposit was of a dark grey colour, and was impalpably fine powder. On analysis, it was found to contain as follows :—

Protoxide of iron	14·22	per cent.
Oxide of zinc...	10·8	,,
Sulphate of zinc...............	13·70	,,
Alumina	8·20	,,
Lime..............................	12·32	,,
Magnesia	5·03	,,
Chloride of sodium	4·74	,,
Ammonia	0·70	,,
Thallium	trace.	
Sulphuric acid..................	3·18	,,
Free Sulphur	0·17	,,
Silica..............................	26·60	,,
Carbonaceous matter.........	4·50	,,
	99·84	

The portion soluble in water had a slightly acid reaction, probably owing to sulphate of zinc, which was found to be present to the extent of [illegible] per cent. It also contained sulphate of lime, sulphate of ammonia, and chloride of sodium. A very small portion of the alumina and silica are dissolved [illegible]

boiling with solution of potash; from which fact, together with the acid reaction of the portion soluble in water, it is inferred that the most of the alumina, lime, and magnesia are in chemical combination with the silica. Sulphuretted hydrogen is copiously evolved on the addition of hydrochloric acid, but not at all on the addition of hot acetic acid; and about 10 per cent. of oxide of zinc is dissolved by caustic potash. It is, therefore, concluded that the sulphide present is sulphide of zinc. The source of the zinc is doubtless the ironstone, as small pieces of zinc blude are occasionally found in the mines, and I have detected its presence in minute quantity diffused throughout the mass of ironstone. Thallium was detected by means of the spectroscope. A portion of the deposit held on a platinum wire in the flame of a Bunsen burner gave faint but unmistakeable indication of the presence of this metal. An attempt was made to estimate the amount by treating about 1,700 grains according to Mr. Crooke's method of separation; but although the amount obtained in this manner gave greatly increased indications of its presence in the spectroscope, yet there was not a sufficient amount obtained to make a quantitative estimation. I am inclined to think that the thallium is not derived from the ironstone, but has had some other source, and that its presence in this sample is accidental, as I have examined various other samples of flue deposit, both from furnaces smelting Upleatham and Rosedale stone, as well as from furnaces using stone from other Cleveland mines, for the purpose of detecting the presence of this substance, but without success.

STEEL.

Mr. T. Spencer read the next Paper, which was as follows:—

The history of the manufacture of steel in this locality commences at a very early period; for we find that, probably 300 years ago, a colony of Germans settled at a place on the river Derwent, within a few miles of this town, and, according to tradition, there established this branch of local industry, where they also attained some celebrity as manufacturers of swords and edge tools. The names of these immigrants who, it is stated, took refuge in this country, that they might enjoy religious liberty, were Ole, Mohl, Voos, &c., &c., and some of whose descendants still reside in the village where their ancestors originally settled, the names being now Anglicised to *Oley*, *Mole*, &c. The name of this village is Shotley Bridge, and in the wall of an old two-storey dwelling-house, the original materials of which are hidden under a coat of "rough-cast," there still exists a stone above the doorway with an inscription in bad German, to the following effect: —DES. HERREN. SECEN. MACHET. REICH. OHN. ALLF. SORC. WAN. DVZVGLEICH. IN. DEINEM. STAND. TREVW. VND-LLEISIC. BIST. VND. DVEST. WAS. DIR. BELOHLEN. IST. 1691, of which the following is a free translation, showing that the original importers of the steel manufacture to the district were probably good Lutherans, who had suffered persecution for conscience sake:—"The blessing of the Lord makes rich without care so long as you are industrious in your vocation and do what is ordered you."

But there is a much earlier record of these German immigrants than the above; the parish register at Ebchester church containing the following entry, by which it will be seen that the name even then had undergone a change:—"Elliner, the daughter of Mathias Wrightson Oley, was baptized on the 17th day of June, 1628;" and shows, also, that the grandfather of the child then baptized had probably married into a family of the name of Wrightson, at that time resident in the neighbourhood, as appears by several entries in the parish register of the period, clearly marking a third generation.

In all probability the next works of this nature established in this locality were those of Sir Ambrose Crowley, who is described as an ironmonger, and afterwards Alderman and Lord Mayor of the City of London, and who appears to have commenced a manufactory at Winlaton Mill in the year 1691. The names of Landells and Chambers are mentioned as being in this trade at an early period, after whom came Cookson, Spencer, and others, whose works are carried on at the present time.

The manufacture of steel, as at present carried on in this district, comprises the following descriptions:—Blistered, shear, spring, and cast steel, to produce which the following materials are required: iron, carbon in the shape of charcoal, manganese, coal, coke, fire-bricks, and fire-clay—of these the iron and manganese are imported into the district, the former for the best qualities of steel being brought from Sweden. The charcoal, coal, coke, fire-bricks, and fire-clay are produced in almost inexhaustible quantities and of most excellent quality in the immediate neighbourhood: a small proportion of fire-clay, however, having to be brought from a distance for admixture with that found in the locality.

The mode of manufacture in use here is that known as the cementing our converting process, the furnaces used being large enough to contain from 10 to about 23 tons of materials at one time; this material consists of selected iron, and known to the manufacturer as being most suitable for the purpose for which it is ultimately intended. It is placed in the cells of the furnace with bruised charcoal in alternate strata, the whole being covered with a vitreous material to effectually exclude the air, and heat is applied for a period of about eight or ten days, according to the degree of carbonization required. The mass is allowed to cool for several days, and the bars are then taken out in the form of blistered steel. The change that has taken place in its structure, since it was placed in the converting furnace is very marked, for instead of now being of a fibrous nature it is quite of a crystalline character, and it must be reduced or drawn out under rolls or heavy hammers to bring back to it something of its former nature. It is, however, used in the blistered state for many purposes, such as for welding into hammer faces, and for welding to iron for edge tools and for spades and shovels, although cast steel is now fast superseding its use even for these purposes. Spring steel is made by simply reducing with rolls the blistered bars, and shear steel is made by repeatedly drawing down and welding the blistered bars. This last-mentioned description is also being fast superseded since the introduction of mill welding cast steel.

The most important of what may be termed the secondary processes of this manufacture is that for producing cast steel, and it is (among the old methods of making steel) of the most recent introduction. Cast steel is different from all the other descriptions of steel in its fineness of grain, greater strength, and its homogeneity. The first steel used in this country partaking at all of the nature of this description of steel was the Indian Wootz, which was much prized by users of steel, especially by the makers of dies for coining presses, who, it is said, paid the almost fabulous price of five guineas per pound for it. The discovery of the English method of making cast steel is due to Benjamin Huntsman, of Attercliffe, who appears to have arrived at it by a series of experiments. He was a clockmaker, and desired to improve the quality of steel for clock-springs. He was born in some part of Lincolnshire in the year 1704; and, although his family are said to have been German, he must have become thoroughly Anglicised, as he was a strict Quaker. In all probability, this discovery was made before the year 1760, as it had become public previous to his death, which took place in 1776, at 72 years of age. This process was first introduced into this locality, by the late firm of Messrs. Crowley, Millington, and Co., the beginning of the present century, probably about the year 1810, who were next followed by Messrs. Spencer, of Newburn. Afterwards, Messrs. Cookson and Co. erected cast-steel melting furnaces, at their works at Derwentcote; and within the last few years, Messrs. Fulthorpe and Co., of Dunston, commenced this branch of the steel trade. Cast steel is produced by breaking the blistered steel into small pieces, and placing the same in crucibles or melting pots, capable of containing 36 to 40 lb. weight each, two of which are placed in each melting furnace. A plentiful supply of coke is now filled into the furnaces, and by the aid of a strong draught of air, an intense white heat is obtained and kept up for three or four hours, according to the nature of the steel required. When it is ascertained that the steel is perfectly melted, the crucibles are taken out and their contents poured into iron moulds conveniently placed near, and left to stand until in a cool enough state to be taken out as cast-steel ingots. These ingots are afterwards reheated and hammered or rolled, or it may be both hammered and rolled, according to the description of article for which it is intended to be used. To produce large ingots, a number of crucibles containing liquid steel are brought out of the furnaces, quickly following each other, and a continuous stream is kept flowing into the mould. There is scarcely a limit to the size of ingot that may be made in this way, as was evidenced by the monster block of steel exhibited by Krupp, of Essen, at the International Exhibition, in London, last year; but great risks are run of getting an unsound ingot, as the least delay in getting out every crucible of steel in perfect order might cause a cessation of the stream, and thus make an unsound casting. In the year 1839, a great improvement was made in cast steel by Josiah Heath, by the introduction of manganese. Having described the various processes that the several different kinds of steel undergo in its manufacture, it may be useful to notice some of the new methods that have been tried in the neighbourhood.

The method of making steel by the cementing or converting process, as already described, may be called the indirect method, because the object of the process is to deprive, in the first instance, the pig iron of the whole of its carbon, making the product as nearly as possible a pure malleable iron, and afterwards imparting to it again the necessary quantity of carbon to make it into steel. The new methods seem to aim, for the most part, at making steel by a direct process, without depriving the pig iron of the whole of its carbon, and without reducing it into a malleable iron condition. This is effected by extracting a large portion of carbon, but taking care to leave in a sufficient quantity to make steel, the object being to save the great waste of metal attending the puddling of iron, as well as the actual cost of that process. Of these last methods the Uchatius process is one that was extensively experimented on a few years ago at the Newburn Steel Works, and the following is a short description of the manner in which the process was carried on. Pig iron, of a first-class quality, was melted in a reverberatory furnace, and run into a tank filled with cold water, where it was reduced into granules; this granulated cast iron was mixed with pulverised oxide of iron and some alkaline earths, and the whole put into the ordinary steel melting crucibles, and then placed in the furnaces, to which heat was applied in the usual way until it was brought into a fluid state. By this method it was thought that the degrees of hardness of the steel was capable of being regulated by the size of the granules, and by the quantity of oxides used; but after a great number of experiments, at a cost of little under a thousand pounds, on attempting to work it in large quantities, it was found that the product was so uncertain in the qualities necessary to good steel, that the process was altogether abandoned. This irregularity of the produce was probably caused by the uncertain quantity of carbon in the pig iron used.

A method of making "puddled" steel has been tried in this locality, but without success. This process was a patented invention of Riepe, a German, and consists in puddling cast iron in a furnace constructed specially for the purpose, until it is observed to be in the condition of steel. This state is found to exist when a particular form of bubble appears on the surface of the metal.

The Bessemer process of making steel has also been introduced into the district at Tudhoe, near Ferryhill, but with what success the writer is not able to say. The operation, as is generally known, consists of blowing atmospheric air through a mass of melted cast iron until the carbon and the whole of the impurities of the iron are burnt out of it. This process has been so ably described by Mr. Bessemer himself, at the meeting of the British Association, at Cheltenham, that it is unnecessary to give a detailed description of it here; but it may be mentioned, that he commenced by extracting only a portion of the carbon, intending to leave in a sufficient quantity to produce steel, but the difficulty of adjusting the exact amount finally led him to extract the whole, and afterwards restore the exact quantity requisite by adding a measured amount of highly carbonized cast iron. Experiments in making cast steel from the Taranaki sand from New Zealand, and also from another similar sand from the coast of Italy, have been tried at Newburn with a result of getting an excellent quantity of steel; but, although yielding about 51 per cent. of metal, the cost of its production, without including anything for the sand, was so great that it would not answer commercially. It may be mentioned that this description of metallic sand appears to possess the remarkable property of not becoming oxidized when kept in a moist condition; and the writer would call the special attention of chemists and metallurgists to the fact, with the view of arriving at (what would be an invaluable discovery) the production of iron or steel that would not be subject to the destroying action of the oxygen of the atmosphere.

The articles manufactured from steel in this locality are very numerous, amongst which may be mentioned railway axles, tyres and springs, piston rods, motion bars and files for engineers' use, rings for Blakeley guns, shot, &c., the great bulk of tonnage being railway springs of various kinds; buffing, bearing, and traction in the laminated form,

as well as the volute spring originally made in this country at Newburn, and of which there have been many hundreds of thousands made the last few years. The rings supplied for guns made in this district have been pronounced by the consumers superior to any others. A firm, in this locality, has been appointed makers of springs for Mr. W. Bridges Adams' patent for the application of circular springs between the tyre and the frame wheel for all kinds of rolling stock on railways; and it is stated that springs applied in this manner effect an increased durability in Staffordshire tyres of 50 per cent. over Krupp's cast-steel tyres without the springs.

The estimated annual value of the steel manufactures of the district is about £100,000, giving employment, at the present time, to about 300 persons, and consuming annually about 15,000 tons of coals. There are in the district nine converting furnaces and 52 cast steel melting furnaces, of which the following is a list of firms having those furnaces:—Messrs. John Spencer and Sons, Newburn, 6 converting and 36 melting furnaces; Messrs. Cookson and Co., Derwentcote, 1 converting and 6 melting furnaces; Messrs. Fawcus and Co., Swalwall, 2 converting and 6 melting furnaces; Messrs. Fulthorpe and Co., Dunston, no converting and 6 melting furnaces.

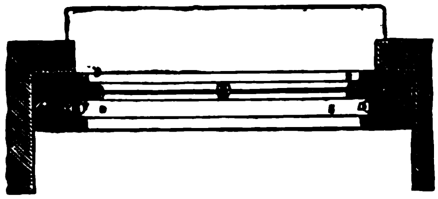
As far as can be ascertained, it would appear that the number of persons employed in this trade in 1838, would be from 70 to 80, and the weight of steel produced annually at that time would be about one-ninth the quantity now produced. The prices of steel range from about £18 to £112 per ton, according to the description, the quality, and the size. This district is highly favourable for the development of the manufacture of steel of the best quality, owing to the facility and cheapness with which a supply of iron can be obtained from Sweden—freights frequently being as low as 3s. 6d. per ton—and also owing to an abundant supply of cheap fuel and labour in the neighbourhood. The business requires, however, the most vigilant attention of thoroughly practical and experienced persons in its management to attain any considerable amount of success.

MEEARS' IMPROVEMENTS IN FITTING SASH FRAMES AND SASHES.

This invention has for its object the arrangement and fitting of sashes in such manner that they shall work without noise, and shall be so packed as to be practically air-tight and water-tight, to exclude dust, and be prevented from vibrating or shaking. For this purpose, instead of suspending and working the sash as at present by lines, weights, and pulleys, the patentee fits it with tubes of elastic material charged with atmospheric air or with gas. These tubes are attached to the sash, one on each side thereof, in a groove or recess therein, and (when working with the sash) they slide up and down in corresponding grooves or recesses in the jambs, or fixed sash frame or window frame, and thus retain the sash at any required height in the frame. Each such groove or recess may be semicircular or semi-elliptical in horizontal section, and when the sash is in the frame each recess in the sash has opposite it a corresponding recess in the fixed sash frame or jamb; such two opposite recesses, when together, form a cylindrical or elliptical space, in which is the tube fitting closely, one-half in the sash groove, and the other half in the frame or jamb groove. The tubes are made of caoutchouc or gutta percha, or of caoutchouc or gutta-percha compounds, or of other flexible and elastic material, and are hermetically closed or secured at both ends. They are charged by pumping or otherwise with air or gas under such pressure as may be required to sustain the weight of the sash by means of any suitable apparatus for injecting the air or gas and closing the same when filled, as is well understood.

The accompanying drawing is a horizontal section of a sash and frame arranged according to this invention.

A, A, are the jambs or styles of the fixed sash frame or window frame; *a*, *a*, semi-cylindrical or semi-elliptical grooves therein; B are the sash styles, and *b* are grooves therein corresponding to the grooves *a*; D are tubes of elastic material charged with air or gas, and closed at both ends. These tubes are cemented into the grooves *b*, and when they slide up and down with the sash they work in the grooves *a*.



In carrying out this invention where a new frame is to be constructed, then, instead of the present frame or style (formed hollow to receive lines, weights, and pulleys, and with a parting bead), the patentee fixes solid jambs, one on each side of the sash frame, and forms in each jamb a groove, as above described, for the tube to work in; but he applies the invention to window frames already constructed by removing the portion next the sash, and replacing it by a suitable solid grooved jamb; or the jamb may be attached to the ordinary frame. The window frame may be so constructed that the sash may be bodily removed from it (when needful, as for convenience of cleaning, &c.) by forming the lower half of one jamb in two parallel portions—the portion A^1 next the wall being a fixture, and the portion A^2, in which is the groove *a*, being screwed or otherwise attached to the part A^1, so that it may be removed from it when required to allow of the sash being withdrawn from the frame. And if it be desirable to add means of ventilation, the bottom rail of the lower sash, or the top rail of the upper sash, or both these rails may be made hollow, and perforated on both sides; the perforations on one side being respectively opposite those of the other side, and in the hollow of the rail is closely fitted a tube perforated on both sides, and capable of being slidden to and fro longitudinally within the rail by a handle projecting through a slot. When the tube or box is so slidden as to bring its perforations opposite those in the sash rail, currents of air will pass through; these currents being intercepted when the parts of the tube or box without perforations are brought opposite the perforations in the rail. The holes may be disposed in plain rows or in ornamental figures. Also ventilation may be afforded by other arrangements in the upper and lower rails or in the glass.

The invention is applicable to house, carriage, and other sliding sashes, whether fixed vertically or otherwise; and also to the covers or sliding parts of cases or other receptacles from which it is desirable to exclude air and dust.

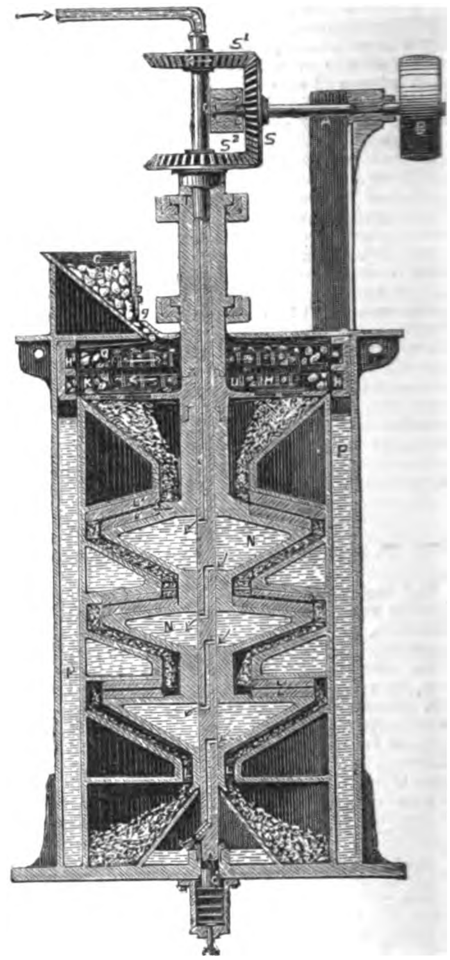
MOSHEIMER'S QUARTZ-CRUSHING MACHINERY.

The following improvement in machinery for crushing and grinding quartz, &c., has been patented by Joseph Mosheimer, of Dolgelly, Merioneth, Wales:—

The nature of this invention consists in combining in the same machine the two principles of crushing and grinding quartz and other substances.

First, the quartz or other substance is crushed by centrifugal force, and then it is ground fine by suitable grinding machinery.

In reference to the first operation, the patentee observes, that if a piece of rock or ore is let fall on to a hard surface from a given height, it will, in proportion to the height from which it has fallen, be more or less broken to pieces. Now, if force be employed to throw a piece of quartz at, for instance, the velocity of 600-ft per minute against a solid piece of iron, such a tremendous blow is given to the quartz that it will be thrown back and shattered to pieces, and in course of time, if the blows are repeated, the quartz will be reduced to as fine a state as may be required; but in order that every particle which escapes reduction by this operation may be reduced to powder, the inventor places under the crushing machine a grinder, which acts on the plan of a grinding-mill. This grinder is constructed entirely of iron, and is kept cool by a continual stream of water which is made to pass through its centre, as shewn in the accompanying drawing, which represents a vertical section



taken through the centre of the machine. It will be seen that the water enters the machine by the hollow shaft C, as indicated by the arrow, and fills all the empty spaces at N, N, inside the grinding surfaces, and it is finally discharged at O, as shown by the arrows. The outside of the whole machine is also kept cool by water surrounding the grinder in the hollow jacket P, P. The machine is set in motion in the following manner:—

A is the driving shaft, on which is fixed the pulley B, which is driven by steam or other power; to the shaft A is fixed the bevel wheel S, gearing above in the wheel S^1 fixed to the shaft C, and below in the wheel S^2 fixed to the hollow shaft T. The lower wings K, K, of the crusher, and the grinders L, L, L, are fixed to the shaft C, and revolve in one direction, while the hollow shaft T is turned in the opposite direction; to the lower end of the shaft T is fixed the rotating wheel or wings Q, Q, of the crusher. By this arrangement a double action of the wings K, K, and Q, Q, is produced; for as the wings Q, Q, are placed above the wings K, K, and they run in opposite directions, if a piece of quartz be thrown by the lower wing it will be caught by the upper one and rebounded to the lower wing, or on to the flat revolving plate U, on which the wings are fastened, and so on continually until the quartz is reduced fine enough, it is then discharged through the sieves R.

The quartz to be crushed is introduced through the hopper G, and passes through the opening *g*, from whence it falls to the revolving bottom plate U, and by the centrifugal motion of this plate all the particles are instantly carried to the outer part of the wings K, and then thrown against the fixed grooved sides H, or against the

upper wings Q, Q, by which they are re-thrown in the opposite direction. On the revolving bottom plate U are placed several punched sheet-iron screens or sieves, through which the fine reduced quartz falls, and is conducted to the revolving grinders L, by passing between which and the stationary grinding surfaces L', it will be ground as fine as may be required, and will then be discharged at the bottom through the openings I. At the bottom of the grinder shaft is a set screw C', furnished with india-rubber plates, by which the grinders may be so set as to grind close and fine, and yet to have some elasticity.

IRON-CLADS ON THE MERSEY.

For a considerable time past, says the *Times*, mysterious assertions have been circulated respecting two iron-clads building in Mr. Laird's yard, and the Federal spies have never lost sight of them. Messrs. Laird, however, make no mystery about "El Tousson" and "El Mounassir," as the ships are named. They are, undoubtedly, built on French account, and it is understood that the French Vice-Consul has given the Collector of Customs satisfactory explanations respecting them. "El Tousson," which was launched some time ago, will be ready for a trial trip in a month or six weeks. "El Mounassir" was only launched on Saturday, but already a portion of her machinery is on board. Perhaps there are not two more formidable frigates afloat. They are 230 ft. over all, 42 ft. beam, with 19 ft. 6 in. depth of hold. Tonnage, 1,850 o.m.; horse-power 350. They will combine speed with good sea-going qualities. They are very flat-bottomed, with exceedingly fine ends, and will sit low in the water. Their draught when loaded will be about 15 ft.; estimated speed, 11 knots. The stem is so formed that the vessel may be used as a ram, and the stern which overhangs affords protection to the screw and rudder from shot or collisions. The rig is that of a bark, the masts, which are telescopic, and the lower yards, being of iron. The armour-plating on the sides of the vessel is 4½ in. thick amidships, and rather less at the ends. The plates, the joining of which together is imperceptible, are fitted into a teak backing of great strength. The deck is of 5 in. teak, protected with iron. The bulwarks let down in case of action in order to allow the turret guns to fire over them. They have two cylindrical turrets on Captain Coles' principle—one before and the other abaft the engine-room, heavily plated. These turrets are made for two guns each. The pilot-house is formed of teak and iron. At either end of the vessel are raised decks, which afford excellent accommodation for the officers and crew. In the captain's cabin provision is made for two heavy stern guns, and heavy guns can be trained from the forecastle deck. These vessels have capacity for 300 tons of coal. All the machinery is below the water-line. Several experienced naval officers who have inspected the vessels, have expressed opinions most gratifying to their designers.

In the adjoining dock is Her Majesty's steam-frigate "Agincourt," of 6,720 tons. The vessel is being constructed in a dock which was adapted specially for the purpose, and is now one of the finest in the kingdom. It is about 400 ft. long, with an entrance 75 ft. wide, and a depth of water on the blocks of 24 ft. at average spring tide, or 26 ft. at a high spring tide. Rapid progress has been made during the summer months—about three-fourths of the ironwork of the hull is now fitted in place, and a large proportion of this completely rivetted and finished off, so that the carpenters have commenced with the woodwork; some six or seven streaks of the teak backing for the armour-plating are fixed on amidships, and various checks, waterways, planking, &c., are being prepared for the different decks. The forgings for the stem and stern frames have, as usual in these very large ships, required a longer time to make than was expected; but the lower part of the stem has now been in its place for some months, and the stern-post, weighing some 35 tons, was finally erected last month. The remaining parts of the stern and the rudder-post will be complete in a few weeks, and then the extreme bow and stern of the vessel will be rapidly closed in. Large quantities of the 5½-in. armour-plates have been received; and as all the machinery for preparing and fitting them has been complete and at work for some time, it is expected that rapid progress will be made with fixing them to the sides of the frigate. The winter weather will not have the effect of interfering with the progress of the work to the extent usually to be feared in this climate, as the whole ship and dock is covered with a shed, under which are placed the travelling cranes and other appliances for carrying on the work.

ON PRINTING TELEGRAPHS.

By Professor D. E. Hughes.*

The Hughes system depends for its correct action on the subdivision of time between each signal or letter, and the contact for each wave of electricity of the same duration. All other systems depend either upon the number and duration of different signals to produce the letter intended, or upon a certain number of signals indicating a certain letter. In order to obtain the results, we must secure, 1st, the perfect synchronism, or time-keeping, of two or more instruments; 2nd, the sending of the currents should be perfect as regards intervals of time and duration of contact; 3rd, the arrival of the current should be perfectly recorded, both as regards the intervals of time and the signals obtained. The instrument is driven by a weight acting upon a train of wheels, and its speed is governed by a vibrating rod. The type-wheel revolves continuously, and carries, by means of bevel wheels, a contact-making arm, which travels around a disc of pins acted upon by the finger-keys. Whenever any one of these keys is pressed down, the corresponding pin comes in contact with the revolving arm at the time wished for. The current is thus sent on the line, passing through the electric magnet, detaching the armature, which, in its rapid upward motion, comes in contact with a detent, which looks at will a small shaft to the train in motion. A cam on this shaft raises the paper against the type-wheel, causing the impression of the letter intended on the paper. At the receiving station the current acts in the same way as in transmission, detaching the armature, thus permitting the printing shaft to make one revolution, and to take the impression of the intended letter once for each current received. The transmitting and receiving instruments are brought into unison by a detent on each, which, on being pressed, stops both type-wheels at a given point, and on being released by the electrical wave, starts them both at the same instant of time. After a detailed description of the mechanical arrangements of the instrument, the methods of obtaining the results, &c., the Paper supplied the following particulars as to the special merits of this invention over others:—It will be seen, from a careful study of this instrument, that it possesses special merits not only for land lines, but for long submarine lines, from the fact of its requiring but one wave to each letter, and the sensitiveness and simplicity of the electrical arrangements. Theoretically its speed is three times greater than the Morse; and this has been fully borne out in the numerous practical trials the instrument has had. The following rates of speed were obtained in different lengths of cables:—

Atlantic cable		...	2,500 miles		4 words	per minute.
Red Sea	,,	...	2,000	,,	6	,,
,,	,,	...	1,000	,,	10	,,
,,	,,	...	500	,,	24	,,
Denmark	,,	...	300	,,	22	,,
Tasmania	,,	...	240	,,	30	,,

On aerial lines the average speed of good operators is 40 words per minute. Having stated the special merits of this instrument with regard to the velocity of transmission through submarine cables, and given various tables and particulars as to the force and time of currents, the Paper proceeded:—The electric magnet of this instrument has been also used as a measure of the force of different electrical forces. The adjusting screw on armature when graduated shows the amount of the electric magnetic force that has detached the armature. The same arrangement has been used as a measure of force under different speeds of transmission. The results of experiments in relation to these points were given. The patents for this instrument have been purchased by the Governments of France and Italy after a series of practical trials of one year's duration, and it is now in daily use on their most important lines. In the United States it has been purchased by the American Telegraph Company, and has been in operation there since 1855. The United Kingdom Telegraph Company possess the sole right for Great Britain, and it is in daily operation upon their lines between Liverpool, Manchester, and London.

* Read before the British Association, August, 1863.

A GREAT LAKE TUNNEL AT CHICAGO.

The Board of Public Works of Chicago, after considering the numerous plans suggested for obtaining a supply of pure water for the use of the city, are more fovourably impressed with that of a "Lake Tunnel" than either of the other plans, and they have already organised a corps of men to investigate the character of the bottom of the lake, to ascertain if the project is practicable. It is known from artesian borings on the lake shore, at Lill's brewery, that, about 20 ft. below the surface, a clay formation commences, which continues upwards of 100 ft. further. Wherever the investigation has been made, the bottom of the lake, where the water is more than 20 ft. deep, is clay. Should this clay prove to be continuous, and free from either beds of sand or gravel, a tunnel can easily be constructed, of sufficient capacity to supply the city for several years, and still others to increase the supply, if the first proves a success. The plan proposed by the Board contemplates the sinking of octagonal cribs 80 ft. in diameter, with central spaces, say 30 ft. in diameter, leaving an average of 25 ft. thickness to the crib around the shaft. In the central space, protected by the crib from the action of the waves, it is proposed to sink iron cylinders 9 ft. in diameter, by the pneumatic process. The outmost shaft would be constructed with reference to its becoming the inlet for the water. The others might be removed to such a depth as not to interfere with navigation.

It is proposed to construct the cribs in still water, plank their bottoms and sides water-tight for several feet up, fill them with as much stone as they can safely carry, tow them to their places, and sink them by letting water into their bottoms, and then to fill them up as promptly as possibly to their tops, with stone previously provided. Cribs of this shape and size would be stronger, and better calculated to resist the action of storms, than cribs of the same width and construction placed in a straight line. The shafts are to be air-tight iron cylinders, jointed together in sections of 6 ft. to 10 ft., and 9 ft. in diameter. They are to be sunk by the pneumatic process, which consists in exhausting the air from them to sink them, and in compressing the air sufficiently within them afterwards to force the water entirely out of them through syphons, thus allowing excavation and other kinds of work to be performed in them.

The estimated cost of excavation and masonry for the tunnel is 143,000 dols., or 13.54 dols. per lineal foot; and for the tunnel complete, 307,552 dols.

Two large scows, with all necessary apparatus on board are towed to their proper locality, and there secured by four anchors. In the space between the boats, a two-inch gas pipe is lowered and rests upon the surface of the earth, the top being 2 ft. or 3 ft. above the surface of the water. The auger is then passed down through the pipe, and worked by two men, the pipe being held in place by others. Both the outside pipe and the auger are lengthened, as circumstances may require, by the additions of joints or sections, which are readily screwed on. The pipe and auger are drawn out and lowered, by means of a derrick about 25 ft. high, with rope and tackle. Up to the present time three localities have been examined—the first three-fourths of a mile from shore. Here the water was 23 ft. deep, with a covering of four inches of sand. They penetrated 30 ft. deep, and found nothing but blue clay. The second locality was 1½ miles out. Here the water was 31 ft. deep, with about the same depth of sand. The auger was sunk 30 ft. with the same result. The third, and the last locality, was about 2½ miles due east from the water-works. Here the water is 36 ft. deep, clear and cool. The earth was here penetrated 30 ft. below its surface. The surface is covered a foot in depth with a mixture of sand, and soft mashy clay. After penetrating 6 or 8 ft., the clay becomes thick, and is harder the deeper it is penetrated. It is of a bluish slate colour, of very fine grain, with little or no grit, and would probably made excellent brick. It is apparently fine enough for pottery ware. The clay is of about the same character the entire depth, wherever the borings have been made.

At several points along the western shore of the lake there is an outcrop of limestone. A ledge of this is seen at Lake View, and another at Cleaverville, about equidistant from the mouth of the river. In order to be satisfied that none of these ledges exist in the line of the proposed tunnel, borings will be made the entire length, about 100 ft. apart. The investigations will be made about half a mile nearer the shore than those last made. This important pioneer work has been entrusted to competent and faithful men; and the Board of Public Works have reason to be very well satisfied with the result of the investigations thus far.

NEVIN AND COPPIN'S IMPROVEMENTS IN FLAX AND HEMP MACHINERY.

FIG. 1.

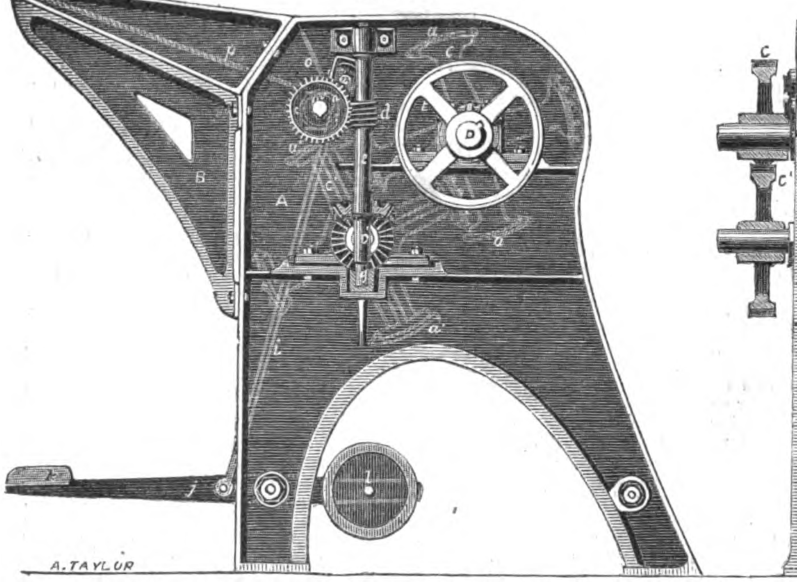


FIG. 2.

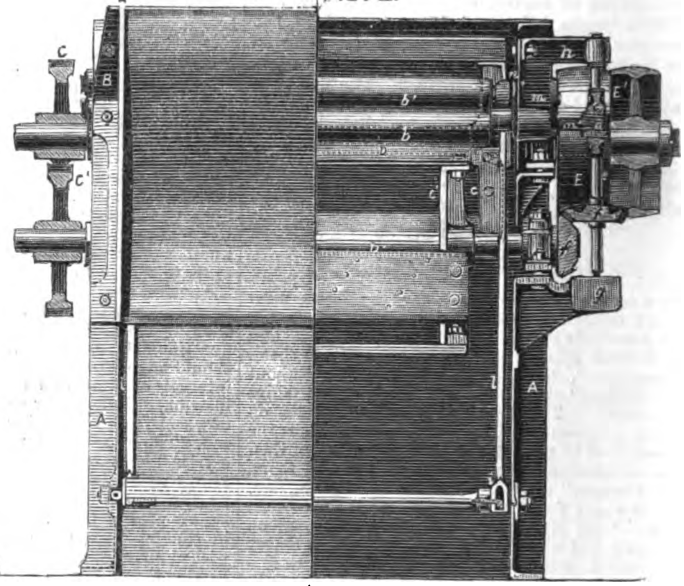


NEVIN AND COPPIN'S IMPROVEMENTS IN FLAX AND HEMP MACHINERY.

Messrs. David Nevin, and William Coppin, of Londonderry, Ireland, have patented the following improvements in machinery for clearing and separating the woody parts from the fibrous portion of flax, hemp, or other like material. For this purpose two sets of revolving flat or curved bars are used, bolted or otherwise secured to arms keyed on to two separate parallel shafts revolving towards each other. The bars of one shaft enter between the arms of the other shaft. The bars of one set pass between the bars of the other set, and are kept from contact by means of toothed wheels of equal diameters, and equal number of teeth, keyed on the two shafts working into each other. One or more of the bars in each set are provided with short teeth for the purpose of keeping the fibre straight and clear. Above the revolving sets of bars is placed a cover, having a rectangular opening through which to pass the fibrous material, and by the action of the bars both sides of the flax or other like material are cleared at the same time. An improved set of holders or clips for holding flax, hemp, or other like material while being dressed or cleaned is provided. Each holder or clip consists of two sets of bars or fluting faced or covered with india rubber or other like material, having a joint or hinge at one end; the two sides closing fit into each other, and are held together by the aid of springs and rackwork; one of these holders being placed or fastened on the end of the material to be dressed, the other end is passed through the opening in the cover of the machine and dressed between the revolving sets of bars, and when sufficiently acted on is withdrawn, and the dressed end is secured in another clip or holder, the first then being removed, and the undressed end passed through the opening and dressed in like manner.

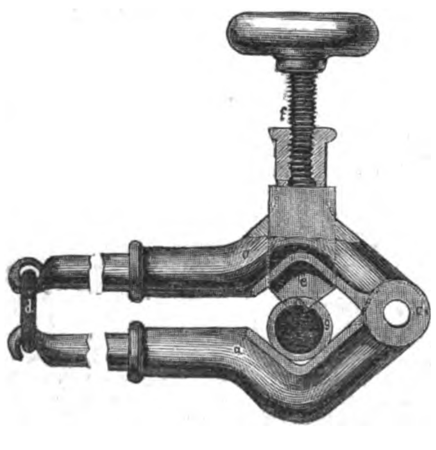
Fig. 1 is an end elevation, fig. 2 a front view (part in elevation and part in section) of a machine constructed according to this invention.

A, fig. 1, is a side frame enclosing the revolving beaters and feed rollers; B, frame for supporting the feed boards; C, C[1], centres or arms on which the beaters are secured; D, D[1], shafts for carrying the centres; E, E, a fast and loose pulley on shaft D; G, G[1], spur wheels on the shafts D, D[1]. *a*, *a*, *a*[1], *a*[1], beaters with teeth for keeping the fibre straight; *b*, *b*[1], rollers for feeding, either plain or fluted; these rollers the patentees prefer to employ, especially when the feed board, on which the fibre to be acted on is spread, is only slightly inclined, but when the feed board is set at a considerable inclination, the rollers may be dispensed with; *c*, worm wheel mounted on end of lower roller spindle; *d*, worm or screws for communicating motion to roller; *e*, upright shaft; *f*, *f*[1], wheel gearing mounted on upright and beater shafts; *g*, footstep; *h*, bracket for securing top of upright shaft; *i*, rod for connecting top feed roller with lever *j*; *k*, footboard for depressing lever and tightening roller on material when in operation; *l*, counterbalance for raising roller; *m*, *m*[1], feed roller spindles; *n*, *n*, bushes in framing (the upper one made to rise high enough to admit the material); *o*, guide plate for conducting material between rollers; P, food board on which the material is evenly spread for feeding the machine.

BARRACLOUGH'S APPARATUS FOR CUTTING METALLIC TUBES OR PIPES.

Letters Patent have just been granted to Thomas Critchley Barraclough, engineer, Manchester, for improvements in appliances for cutting pipes or tubes of iron or other metal.

The apparatus consists of two metallic jaws, by preference made of malleable or other elastic description of cast iron or steel, and hinged together at one extremity and so formed near the hinge or joint as to receive the pipe to be cut at right angles to the cutters employed; to these jaws, at the farther end to the hinge, two steel



or wrought-iron rods are attached. The cutter, which is made of steel, slides vertically through one of the jaws, and its cutting force or pressure may be adjusted by means of a thumb-screw above it. The pipe to be cut is placed in the hollow made for its reception, the two opposite ends of the rods are then brought nearly together and secured by a link, links, or other substitute, the jaws being thus caused to hold the pipe, and the cutter is tightened thereupon. If now the pipe be held firmly in a vice, and the apparatus turned several times round in a direction at right angles to the axis of the pipe, the cutter will penetrate the material and dissever the tube. If the metal or substance of which the tube is made be very thick, more pressure is to be applied gradually to the cutter by means of the screw until it is cut through.

The accompaning figure represents a side view (shown partly in section) of the apparatus for cutting tubes, shown in the operation of severing a tube, and in which *a*, *a*, are the jaws made of malleable cast iron or other metal, which are hinged together at *c*, and to which are attached the rods *b*, *b*, made of steel or other slightly flexible metal, and are retained in the position shown by means of the link *d*, or other convenient means of attachment. The cutter *e* is made of steel, and slides in a slot in the upper jaw, and may be tightened to any required pressure by means of the screw *f*, so as to cause the cutting points to enter the tube *g*, which is held in a vice or otherwise fixed whilst the apparatus is turned round, causing the cutter to enter and by continued turning to sever one portion of the tube from the other.

MORELAND AND CHAPPELL'S IMPROVEMENTS IN WINDING, WARPING, OR DRESSING MACHINES.

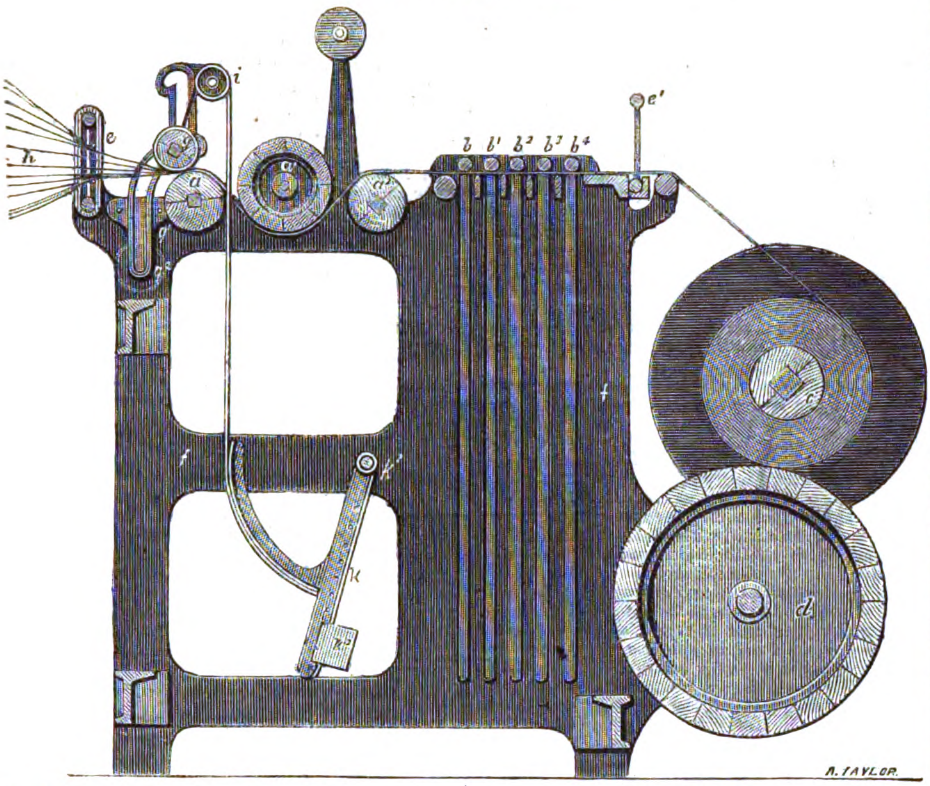
The following improvements in warping and dressing machinery have been recently patented by William Harrison Moreland and John Chappell, both of Loop Bridge Mill, near Belfast:—

The invention consists in the application to the ordinary winding, warping, beaming, or dressing machines that wind from the spools or bobbins, of a drag roller or rollers, for taking up the slack yarn caused by the over-running of the spools or bobbins from which the yarn is being wound.

The method of this application will be understood from the following description and drawing which is a section of a warping machine as used for linen yarns, with this improvement applied to it.

a, *a*[1], *a*[2], are the ordinary rollers of the machine, over and under which the yarn passes, *a*[1] being the measuring roller; *b*, *b*[1], *b*[2], *b*[3], *b*[4], are

MORELAND AND CHAPPELL'S IMPROVEMENTS IN WINDING, WARPING, OR DRESSING MACHINES.



the falling rods for taking up the slack yarn when backing off to find an end, &c.; c is the beam whereon the yarn is wound; d, the roller that drives it by surface contact; e, e^1, are the reeds or guides for the yarn; f, the framing of the machine. The drag roller g rests upon the yarn, where it passes on to the roller a, the direction of the yarn as it comes from a creel or bank which carries the spools or bobbins being shown by the lines h. The roller g has a pivot at each end, which pivots pass severally through an eye fastened to a strap or other suitable material led over the carrier pulley i, and connected to a weighted balance lever k, supported by a stud k^1 fixed to the framing f. The pivots on the ends of the rollers g, after passing through the eyes of the straps, enter guides g^1, which are fastened one at each side of the framing f. The slot of these guides is continued below the centre of the roller a, to allow the roller g to fall as the yarn is slackened.

The action of this roller g is as follows:—When the machine is stopped, the spools or bobbins are liable to over-run, and thus leave the yarn slack until the winding recommences, but the roller g, resting wholly or partially on the yarn, falls down the slot or guide as soon as the yarn begins to slacken by the stoppage or slackening of the winding, until it attains the dotted position g^2. To prevent the weight of this roller from continuing to take up the yarn at the first speed, it is caused to raise the lever k from its vertical position, as shown, to a position approaching a horizontal one, thus gradually increasing the power of the weight k^2 until it, with the slight tension on the yarn, balances the roller g. By this means a uniform tension is secured to the yarn throughout the beam, and the action of the measuring roller a^1 is rendered certain.

The slack roller or rollers may be placed either before or behind the reed or first guide e_1 through which the yarn passes, and be supported either together or in part only by the yarn.

This improvement is applicable to all beaming, warping, or dressing machines that wind from the spool, whether for flax, cotton, or other yarns.

GUN-COTTON.

DR. GLADSTONE read the chemical portion of the report of the Committee on Gun-Cotton before the British Association. The report stated that during the year the committee had been put in possession of the fullest information on the subject, by Baron William Von Lenk, Major-General of the Austrian Artillery, who was the inventor of the system by which gun-cotton was made available for warlike purposes; and Professor Abel, chemist of the War Department, by permission of the Secretary of State for War, had communicated to them the information given by the Austrian Government to the Government of this country. The committee had made no experiments themselves. The subject might naturally be divided into two conditions—the chemical and mechanical. Taking the chemical first, that department included the manufacture of gun-cotton itself, its liability or non-liability to spontaneous combustion, and the nature and effects of the products into which it was resolved on explosion. As to the chemical nature of the material itself, the gun-cotton differed from the gun-cotton generally made, in its complete conversion into a uniform chemical compact. General Lenk secured the production of his gun-cotton by several precautions. Of these the most important were, the cleansing and perfect desiccation of the cotton as a preliminary to its immersion in the acid; the employment of the strongest acids obtainable in commerce; the steeping of the cotton in a fresh strong mixture of acids, after its first immersion and consequent imperfect conversion into gun-cotton; the continuance of this steeping for 48 hours. Equally necessary is the thorough purification of the gun-cotton so produced from every trace of free acid. There is one part of the process of the manufacture, the value of which is not open to doubt—viz., the treatment of the gun-cotton with a solution of silicate of potash, commonly called water-glass. The chief advantages of the material were set forth in the mechanical report; but it was here stated that the fact that gun-cotton is not injured by damp like gunpowder, is one of its recommendations; while a still greater chemical advantage which it possesses arises from its being perfectly resolved into gases on explosion, so that there is no smoke to obscure the sight of the soldier who is firing, or to point out his position to the enemy, and no residue left in the gun to be got rid of before another charge can be introduced.

Mr. Scott Russell, F.R.S., submitted the mechanical report. After a long and careful examination, the committee were able to understand and reconcile themselves to the fact that greater mechanical effects are produced from gases generated by gun-cotton than by those generated by gunpowder. The same quantity of gases and the same number of atmospheres seemed to be produced from both materials, and it did not appear to mechanical men that there was a greater advantage in gun-cotton in that respect. The next inquiry was into the distinctive nature between the action of these gases in gunpowder and the action of those gases in gun-cotton. The great waste of force in gunpowder constituted an important difference between it and the gun-cotton, in which there was no waste. Gunpowder consisted of about 68 per cent. of solid matter, only 32 per cent. of which was useful gases. It might be seen, therefore, that one-third of gunpowder is not directly useful in producing gases. There was another peculiar feature of gun-cotton—it could be exploded in any quantity instantaneously. Gen. Lenk had discovered the means of giving gun-cotton any velocity of explosion that is required by merely the mechanical arrangement under which it is used. Gun-cotton in his hands had any speed of explosion, from one foot per second, to one in 1000th of a second, or to instantaneity. The spontaneous explosion of a large quantity of gun-cotton is made use of when it is required to produce destructive effect, and it is found that the condition necessary to produce instantaneous combustion is the absolute perfection of the closeness of the chamber containing the gun-cotton. On the other hand, if they desired gun-cotton to produce a different effect, they must provide for its slower combustion. It must be abstracted and opened out mechanically, so as to occupy a large space, and in this state it can be made to act even more slowly than gunpowder, and come within the limits which render it fit for the purposes of artillery. In general it is found that the proportion of 11lb. of gun-cotton occupying one cubic foot of space, produces a greater force than gunpowder, and a force of the nature required for ordinary artillery. But each gun and each kind of projectile requires a certain density of cartridge. Practically, gun-cotton is most effective in guns, when used at a quarter to one-third weight of powder, and occupying a space of one and one-tenth of the length of the powder cartridge. In regard to safety, it was a fact that during the ten years of the manufacture of General Lenk's gun-cotton at the imperial factory at Kirtenberg, and during ten years storage of that material in the imperial magazines at Steinfeldt, in which thousands of cwts. were deposited, not one single accident occurred. The best temperature for gun-cotton was 136 degrees centigrate, or between 277 degrees and 338 degrees Fahrenheit—a temperature sufficiently high to ensure safety for all practical purposes. The cost of production was considerably less than that of gunpowder, the price and quantities being compared, which will produce equal effects. As to the mechanical purposes of the cotton, it is used for artillery in the form of gun-cotton thread or spun yarn. In this simple form, it would conduct combustion slowly in the open air at the rate of not more than one second. This thread was woven into a texture or circular web. These webs were made of various diameters, and out of them cotton rifle cartridges were made by cutting them into the proper length. The cotton web was generally enclosed in india-rubber tubes, in which form it is most convenient. For the explosion of mines it is used in the form of ropes. Conveyance and storage of gun-cotton:—One pound of gun-cotton produces effects somewhat exceeding 3 lb. of gunpowder in artillery. This is a material advantage, whether it be carried by men, by horses, or in waggons. It may be placed in a store and preserved with great safety. The danger from explosion does not arise until it is confined. It may become damp, and even perfectly wet; and, without injury, may be dried by mere exposure to the air. Practical use in artillery:—The gun keeps clean, and requires less windage, and therefore performs much better in continuous firing. In gunpowder there is 68 per cent. of refuse, or the matter of fouling. In gun-cotton there is no residuum, and therefore no fouling. Experiments made by the Austrian Committee proved that 100 lb. could be fired with gun-cotton against 30 lb. of gunpowder. From the low temperature produced by gun-cotton, the gun does not heat. Experiments showed that 100 lb. were fired with a 6-pounder in 34 minutes, and the heat was raised by gun-cotton to only 122 deg. Fahr.; whilst 100 lb. of gunpowder took 100 minutes, and raised the temperature to such a degree that water was instantly evaporated. The firing with the gunpowder

was therefore discontinued, but the rapid firing with the gun-cotton was continued up to 180 lb. without any inconvenience. The absence of fouling allows the mechanism of a gun to have more exactness than where allowance is made for fouling. The absence of smoke permits rapid firing and exact time. The fact of smaller recoil from a gun charged with gun-cotton is established by direct experiments. Its value is two-thirds of the recoil from gunpowder, the projectile being equal. Practical application to destructive explosion:—It is ascertained that the same shell is exploded by the same volume of gas generated from gun-cotton and gunpowder into more than double the number of pieces; and it is a startling fact that the stronger and thicker the shell the smaller and more numerous are the fragments. Mining uses:—The fact that the action of the gun-cotton is violent and rapid in exact proportion to the resistance it encounters, tells us the secret of the far higher efficacy of gun-cotton in mining than gunpowder. The stronger the rock, the less gun-cotton comparatively with gunpowder is found necessary for the effect—so much so that while gun-cotton is stronger than gunpowder, weight for weight, as 3 to 1 in artillery, it is stronger in the proportion of 6·27 to that of strong solid rock, weight for weight. It is the hollow rope form which is used for blasting. Its power in splitting up material is executed exactly as you wish. With regard to the military and submarine explosion, it is a well-known fact that a bag of gunpowder nailed on the gates of a city will blow them open. A bag of cotton exploded in the same way produces no effect. To blow up the gate of a city with gun-cotton, it must be confined before explosion. Twenty pounds of gun-cotton carried in the hands of a single man would be sufficient, only he must know its value.—Other effects of the Austrian invention were enumerated, and the Paper throughout was of a most interesting character. The experiments, the results of which were detailed, had been conducted on a gigantic scale.

In accordance with the expressed wish of the Chairman, the conversation which ensued was limited to the chemical aspects of the question, it being intimated that the mechanical features of the subject would be discussed in that Section.

Captain Galton, presuming that there were yet many points that required further investigation, moved that a proposal be submitted to the Committee of Recommendations, that the Committee be requested to continue their labours for another year. He was sure that the War Office would be glad to assist as much in the inquiry as they had hitherto done.

Although the motion for a continuance of the inquiry was not formally put, the suggestion will doubtless be acted upon.

NEW METHOD OF WORKING RAILWAYS BY STATIONARY ENGINES.

Mr. J. F. Spencer read a Paper on this subject, before the British Association, prepared by Messrs. R. and W. Hawthorn. It was as follows:—

The Paper brought before this Section to-day is a description of a method of working a certain class of railways by means of ropes from stationary engines.

A system of working railways by fixed engines and ropes has long been in use on the colliery railways around Newcastle-upon-Tyne, as well as in other districts, and a plan for the same was made the subject of a patent by Mr. Benjamin Thompson, then of Ayton Cottage, in the county of Durham, and was introduced on one or two colliery railways. It consisted of a succession of fixed engines at certain intervals from one end of the line to the other, each engine being employed to work a portion of the railway in the following manner.

The engine gave motion to two rope rolls, and the rope from one of those rolls was attached to one end, and the rope from the other roll was attached to the other end of the train. Whilst one of the rope rolls was disengaged from the engine, and allowed to run loose, the other was in gear, and the rope from it was passed along the line, and round a loop sheave, then brought back and attached to the train. The engine being put in motion the train was dragged to the furthest end of the section worked by that engine at the same time unwinding the rope from the loose roll, and taking it with it to be afterwards employed to drag back the returning train. This was continued throughout the line, each successive engine taking up the train, and carrying it over a section of the line. This method was not a satisfactory one for the conveyance of passengers, as the rider or guard in charge had not sufficient control over the movements of the train, and there is an objection to the carriages being attached directly to the rope, and at such a distance from the motive power. Ropes have been, and are yet, applied in other ways, for instance, on gravitating or descending planes, down which a loaded train passes, having the rope attached to the after-end round a sheave at the top of the incline, and thence down to the ascending train, and thus the descending loaded train draws up the ascending light train; or, where the load has to ascend, a fixed engine is employed to draw it up, and the descending train takes the rope down with it. Ropes are also applied in a variety of ways to the working of incline planes on passenger railways. Thus, there is nothing new in the use of stationary engines and ropes for working railway trains. It will be observed that in all the cases referred to, the rope is attached directly to the carriages.

In the proposed plan now offered to the notice of members of the Association the means of communicating motion to the train give greater security as well as the advantage of avoiding the necessity of attaching a train to the end of a rope, thus ensuring to the guard as complete control over the movements of the train as he now has in the employment of the locomotive engine. In the new system it may be stated without exaggeration that the rope drives the locomotive wheels, and each carriage carries its own railway.

It is proposed with the ordinary construction and gauge of railway to place in the intermediate space between a double line of rails a series of double grooved sheaves fixed in spindles or axles which pass across under the rails extending a little over the centre of each line; a plain wheel or roller is fixed upon each end of the axles by which the motion is communicated to the train from a stationary engine or engines placed at a convenient point of the line—by the means of an endless wire or other rope passing alternately over and under the grooved sheaves to the extremity of a section of the line where it is taken round a large loop sheave and returned to the engine now passing over each sheave which it before passed under, and *vice versa*; the double groove providing for the rope crossing itself without contact.

Having traversed twice along the line of sheaves the rope goes again on to the large winding sheave of the engine, on which a sufficient number of turns are taken to ensure the requisite friction.

From this arrangement of the rope on the sheaves, it will be seen that every alternate sheave runs in the same direction, and every intermediate sheave in the contrary direction; and this motion is communicated to the traction wheels or rollers before-mentioned.

It is proposed to construct the carriages for passenger lines on the principle of those used in America, and on the Canadian railways, of a length of from 60 to 75 ft., and supported on bogies, and capable of seating from 120 to 150 passengers, each carriage to be fitted witn traction bars—these bars extending over two or more alternate traction rollers—and to be furnished with the ordinary flanged wheels for running on the rails. The traction bars, of which there are two, are placed side by side, at such a distance from each other as may be necessary to meet the requirements of the line; and these traction bars are worked either in connection with or independent of each other by a suitable arrangement of levers or other gearing, by which either of the bars can be raised or depressed, thereby bringing a portion of the weight of the carriages upon the traction wheels or rollers, thus giving motion to the train of carriages in either direction. Or both these bars can be raised out of contact with the traction wheels or rollers, and the train left free from all tractive force.

The traction bars will be nearly the full length of the carriage, and the traction rollers will be placed about 18 ft. apart, or at the rate of 293 per mile.

The carriage made in this way is adapted for running with either end first, being provided at each end with a platform, on which the driver stands to work the traction bars; and it is considered that for ordinary traffic one carriage will be sufficient to form a train, but two or more may be attached to each other, or the number of trains of a single carriage each may be increased to meet the requirements of the traffic.

The motion of the train can be quickly and certainly retarded or stopped by raising one bar and depressing the other, in the manner of a brake, thereby reversing the direction of the driving motion.

A separate or independent traction carriage may be used, fitted with the traction bars and gear; but it is considered that such an arrangement would, in most cases, only be adding a useless and unnecessary weight to the useful portion of the train.

The present line of underground railway through London, from Paddington to Farringdon-street, is favourable to the use of the locomotive engine, where so much of the surface of the ground under which it passes is unoccupied by buildings, and readily admits of a good deal of open cutting and ventilation at the stations, which cannot be the case where the railway passes under the densely-populated parts of a city, as those projected in London must do. In such cases it will be necessary to provide for working in a continuous tunnel of perhaps three or four miles in length, in which the steam and smoke of locomotive engines would prove obnoxious to a much greater extent than is experienced on the present line, which is only partially an underground railway. As there does not appear to be any means of remedying these evils, except at a very extravagant cost, it is believed that the new system may be introduced with advantage in such cases as are above referred to—viz., railways passing under large towns or in situations where opportunities do not occur of having openings to the surface.

The maintenance of the engines will be considerably less than with locomotives to balance the expense of keeping in working order the sheaves, ropes, &c., which will cost more than an ordinary line.

Both calculation and experiment on the adhesion acquired to propel a train remove any reasonable doubt of being able, by the new system, to obtain sufficient tractive force by the traction bars and rollers, and it is evidently quite feasible to increase this tractive power if required.

With a locomotive a train of 15 or 20 carriages has to be drawn by an intense pressure on six or eight points, and it is this which adds such a heavy item to the cost of railway maintenance. This disadvantage will be to a great extent remedied by the proposed system, the tractive force being more distributed, and consequently the wear and tear diminished. Finally, if such a system as the one proposed can be introduced free from the objections that have hitherto been considered inseparable from the use of ropes, it will greatly facilitate the construction and extension of underground railways without their present drawbacks.

TO CORRESPONDENTS.

Received.—J. B., R. S., H. W. P., S. B., A. A. and Co., T. B., and P.

W. N.—Mr. Obed Hussey, the inventor of one form of the reaping-machine, is dead, long since; he was, we believe, killed on the Boston and Maine Railroad, U.S.

C. F. D. (Walsal).—We cannot answer your first question. In reply to the second, we believe there is no doubt whatever that Mr. W. B. Adams is the inventor of the fish-joint.

An Engine-driver.—The head lights used on American locomotives are very large, quite powerful enough to illuminate a small lighthouse. Such lamps are extremely useful, lighting up the road very clearly for a great distance ahead. They are rather expensive, having very large and beautifully finished reflectors.

Miscellanea.

We have received the following from Messrs. Robinson and Co., Denton Mills, Carlisle:—As an illustration of what can be accomplished by modern machinery, we have pleasure in sending you the enclosed box of biscuits, made from wheat grown upon our reclaimed waste lands formerly occupied as the Carlisle Canal Reservoir, reaped "this morning" by McCormick's reaping machine, thrashed on the spot by a steam thrashing machine, conveyed to Denton Mills, manufactured into flour, and made into biscuits by patent machinery which gained the prize medal at the International Exhibition, 1862.

On Saturday two splendid additions were made to the fleet of the Peninsula and Oriental Steam Navigation Company by the launch of two powerful iron screw steamers, named the "Golconda" and "Baroda," at Blackwall. Both vessels are frigate built, and of the same dimensions—length 295 ft., 2,090 tons register, and 400-horse power.

The principle of the adaptation of double screws to ships of war has been so far acknowledged in its importance by the Admiralty that their lordships have given Messrs. Dudgeon an order to construct a small vessel which shall combine in their most efficient form the double-screw principle which they have successfully brought into public notice.

On Thursday week one of the "Royal Alfred's" armour plates, measuring 15 ft. in length, 3 ft. 6 in. in width, and 4 in. in thickness, was successfully covered with its coating of copper by the "Walenn" process, in the steam factory at Portsmouth. The thickness of the coating was the sixty-fourth part of an inch, and it was deposited with an even and bright surface, notwithstanding that a plate had been selected by the dockyard officials, which was undercut and honeycombed on its outer surface.

The cotton defences of Fort Sumter proved a failure. The guns set the cotton on fire. A part of it fell into the sea, and the rest was saved. King Cotton could not help his subjects.

A Washington correspondent gives the following account of the wheelwright and carriage department of the army at Washington:—Every kind of woodwork repair is done here, for all sorts of waggons and vehicles used in the army, including painting and trimming, and, in occasional times of leisure, new waggons are manufactured. All the broken carriages and fragments are brought here from the army of the Potomac; and so closely worked over, that few fragments are left to be conveyed out of the way. The quantity of these broken down, mashed up, and played-out machines that come into this yard daily is on a gigantic scale; and those who see these traps go in such quantities daily into this yard, and disappear for ever, very often, without knowing that they do go out daily in the shape of good waggons, express their astonishment that the whole city is not covered over with the fragments.

Sweden has abolished all export duties. Among the articles affected by this resolution are several which, it is considered, will be before long imported into England, such as cattle, bones, cast and pig iron, copper, rags, ores or metals, and many kinds of wood.

A report is current at Constantinople that the Turkish Government intends, for the future, to have the metallic currency of the Ottoman Empire coined at the Paris Mint.

We learn that Mr. Freeman, of Cannon-street, the executor of the late James Fenton, so well known as a practical engineer, and whose decease was noticed in our Journal at thetime, is doing honour to his memory by attempting to raise a memorial fund for the education and advancement of his children. We sincerely hope that he will meet with that encouragement so excellent an object deserves. We are not fond of testimonials to the living, because it seldom happens that they are presented to those who really need them, but in this case it must be a simple matter of respect to the memory of a man who while living was greatly estimated.

Some months ago, the keel for a steamer, 300 ft. long, was laid opposite Shanghae. As there is not any timber in that part of China suitable for so large a vessel, it was built of teak, Siam wood, and Oregon pine. The engines are from the Neptune Iron Works, New York, fitted up in Shanghae by Mr. James A. Smith. She is in all respects a first-class steamer for the the Yangtze river service, and is estimated to carry from 1,800 to 2,000 tons of cargo.

Messrs. Deville and Caron have lately been making experiments on the properties of a new gun, metal, a compound of silicium and copper. When copper contains rather less than five per cent. of silicium, it presents a fine bronze colour, is fusible, and rather harder than bronze,—but is perfectly ductile, and can be readily worked without clogging the tools as bronze does. Its tenacity is remarkable, being equal to that of iron. Silicium is the basis of sand, and the manufacture of its compounds with copper may be made by fusing together a mixture of sand, sodium, and copper, with some common salt and fluor spar as flux.

M. Nadar's newly-invented aerial machine, which is occupying considerable attention in Paris, is already nearly half-finished. Its dimensions are so enormous that it will have accommodation, it is declared, for more than a hundred passengers. The first aerial journey is to be made to Baden. M. Nadar will call his balloon the "Quand-Même."

We extract from a contemporary the following description of Hughes' printing telegraph, as exhibited in Newcastle at present:—The machine is fixed to a table or platform not larger than an ordinary chess-board, and is altogether very neat and compact. The electric waves are transmitted by a revolving arm, which acts in concert with a type-wheel. On the face of the instrument are 28 keys, arranged like those of a piano, but occupying less than a third of the space. These correspond with an equal number of metal plates, working upwards through slots formed all round a circular disc, on the top of which, but not in connection with it, the arm and what is called "contact-maker" revolve. The type-wheel and this arm revolve together, and when a key is depressed by the operator, a plate corresponding with the letter touched is raised, and a letter is printed, while at the same instant, by a graduated movement, the paper is carried on a space ready to receive the next impression. The instrument is worked chiefly by women, and very much after the manner of a piano, but with a heavier touch. It prints at both ends of the wire simultaneously, and in clear type, so that the operator sees the message which is being transmitted as it proceeds, and no copying or translation being required, the chance of error is avoided. The speed secured in France and America, by highly-trained operators, is said to have reached from forty to fifty words a minute. At this rate the instrument would print matter equal to a column of the *Times* in a few minutes less than an hour, assuming there was no break in the operation, which probably would be too much to assume. It was brought into use in transmitting a report of the recent speech of Mr. Bright at Birmingham.

The latest discovery in portraiture is an invention, styled by the patentee the "Casket or Crystal Cube Minature," by which a solid image of your head is, by some new development of the photographic art, seen looking with a strange living reality from out the centre of a small cube of crystal, every feature standing out in as perfect relief as though chiselled by the hands of fairy sculptors.

The Secretary of State for War has considered it expedient to establish a uniform rule in regard to the grant of public holidays to the artificers, labourers, &c., in the various branches of the War Department, and has therefore decided that in future the following days only shall be observed as holidays with pay:—Good Friday and Christmas Day, the latter, if falling on a Sunday, may be observed on the following day; the anniversary of the Coronation of the Sovereign; and the day fixed each year for the observance of the Sovereign's birthday.

The gentry and merchants of Galway have subscribed £10,000 for the construction of a graving dock to accommodate and repair the Atlantic mail fleet; but this sum is only one-third of the amount required for the work, and the *Galway Vindicator* urges the necessity of increased exertions upon the Dock Company, in order to raise £10,000 more, which would be sufficient, as the directors of the Atlantic Company have promised individually to subscribe £10,000 among themselves, without however, entering into the Graving Dock Company as a body.

The annual meeting and cattle show of the Royal Irish Agricultural Society took place last week at Kilkenny. The show of fat cattle was extremely good. In the implement department the display was very creditable to Irish engineers. Fowler's steam-plough was at work the three days of the show, and from its novelty in Ireland proved an immense attraction. Our own engineers would find in the Sister Isle a very fair field for the sale of machinery specially constructed to meet the demands of a class who cannot expend much capital. It is sufficiently remarkable that the use of the reaping machine is more general there than here. Its small price placing it within the reach of farmers who are, as a body, really anxious to avail themselves of the benefits of machinery.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c., 250, 251, 253, 274.
BOILERS AND FURNACES, 229, 258.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 227, 236, 259, 263, 280, 281, 282.
SHIPS AND BOATS, including their fittings, 238, 249.
CULTIVATION OF THE SOIL, including agricultural implements and machines, 221, 260, 270, 277.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 233, 262, 275, 279.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 224, 225, 239, 245, 257, 268, 284, 288.
BUILDINGS AND BUILDING MATERIALS, 232, 235, 243, 255, 269.
LIGHTING, HEATING, AND VENTILATING, 242, 244, 247, 248, 266, 273, 287, 289.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 222, 226, 228, 230, 231, 234, 240, 246, 256, 264, 265, 276, 278, 283.
METALS, including apparatus for their manufacture, 223, 237.
CHEMISTRY AND PHOTOGRAPHY, 267, 271, 272, 285, 286.
ELECTRICAL APPARATUS, 241.
WARFARE—*none*.
LETTER-PRESS PRINTING, 251, 254.
MISCELLANEOUS, 261.

221. W. CLARK. *Improvements in syphons applied to draining, irrigation, and other purposes, whereby they self-suspend and resume action according to requirements.* (A communication.) Dated January 24, 1863.

This invention consists in the application of a float which closes the cock for passing water when there is no longer any to remove; the said cock again opens on a return of water in the place to be exhausted, and when once in position, the syphon works automatically. *Patent abandoned.*

222. A. J. SAX. *Improvements in rendering drum-skins and gut-strings less liable to hygrometric influences.* Dated January 24, 1863.

This invention consists in impregnating or coating the skins of big, little, or other drums, tambourines, or other musical instruments of the same class, as well as the gut-strings of violins, basses, violoncellos, or other musical instruments provided with such strings, with a solution of any suitable chemical agent which, after becoming dry, will render the said skins or strings sufficiently impervious to wet as to prevent them from attracting moisture with the same avidity as those bodies are liable to when left in the state they have been made use of up to this moment for the above-mentioned purposes. The liquid the patentee prefers to make use of is collodion. *Patent completed.*

223. R. A. BROOMAN. *Improvements in the manufacture of anvils and other metal articles requiring hard surfaces.* (A communication.) Dated January 24, 1863.

This invention consists—1, in manufacturing anvils by the direct superposition during the casting of two metals united so as to form one body; 2, in the substitution of casting for forging in the manufacture of anvils, thereby diminishing in a great measure both hand labour and expense. *Patent completed.*

224. F. TOLHAUSEN. *Improvements in looms for weaving ribbons.* (A communication.) Dated January 24, 1863.

In this improved loom the batten or lathe is made with twice the number of pieces, but with the same longitudinal dimensions as in the ordinary loom. The second or additional set of pieces is placed underneath the first set, thus increasing the height of the lathe; and the space between the successive warps is made available for placing the reeds through which each double piece of ribbon passes. By this arrangement the operative is enabled to see all the pieces weaving, bearing in mind, however, that in fancy weaving the upper warps are woven the right side up, whereas the lower ones are woven the wrong side up, as each of the shuttles works the upper warp in its ascending course, and the next lower one in its descending course. The batten is divided into two parts which slide on blocks, and can be set more or less apart according to the nature of the work. When one of these parts rises, the other is depressed to an equal amount. To the ordinary jacquard which acts direct on the upper ribbon warps the inventor superadds another having no card cylinder or beam, and acting direct on the lower or additional warps. This auxiliary jacquard is set in motion by means of a double lever, which oscillates between the two jacquards in such a manner that it lifts the shed on one side, whilst it lowers the shed of the other warp. For the said purpose the wires or needles in the first jacquard are made longer than usual, so as to work into the auxiliary and produce the contrary effect therein. The auxiliary jacquard carries a moveable board on its grif to support the hooks holding the threads; when the board descends, all those hooks which are not hung on the blades of the grif or leash-box descend along with it. *Patent abandoned.*

225. F. TOLHAUSEN. *Improvements in machines for carding fibrous materials.* (A communication.) Dated January 24, 1863.

This invention consists in applying doffing combs to each of the rollers that in a certain description of carding engines are set round the main carding cylinder; the object of this addition is either to obtain a greater quantity of carded material, or to produce a finer lap of superior quality. In the former case, the webs produced by the rollers and the combs are at once delivered or taken off either laterally or in any direction by delivery rollers; in the latter case, the webs doffed by the said combs are united into one lap, which is then at once passed through the carding engine again. The said combs are set in motion by any of the devices now in use for doffing combs. *Patent completed.*

226. W. F. STANLEY. *Improvements in mathematica drawing instruments.* Dated January 26, 1863.

This invention is not described apart from the drawings. *Patent completed.*

227. J. B. Fell. *Certain arrangements for working railway engines and carriages on steep inclines, to consist in enabling engines and carriages to travel up and down steep inclines with great facility and security.* Dated January 26, 1863.

For the purposes of this invention, the patentee applies to the engines and carriages, wheels in pairs or sets of two or more, so arranged as to work on either side of a central rail, and to press and hold on such rail with a pressure and holding adapted to the circumstances of each case. In travelling up inclines, the wheels of each pair or set are worked by the engine at a speed, and with a pressure, on each side of the central rail, according to the load and the rate at which the engine has to travel, and the adhesion necessary for taking the load up the incline. In descending the inclines, these pairs of wheels on the engine and carriages are employed as breaks, with an adhesion adapted to the load. These pairs of wheels also hold on either side of the central rail in such manner as to afford a great amount of security against the wheels of the engines or carriages jumping and getting off the lines of rails on which they are travelling. *Patent completed.*

228. A. Smith. *Improvements in certain parts of staples, locks, bolts, latches, and other similar fastenings.* Dated January 26, 1863.

This invention relates to the introduction of a wheel or roller in the keeper of spring locks or latches, and other similar fastenings for doors, lids, and the like, so that, when the same are being shut, the end of the spring bolt comes in contact with the said wheel or roller on the stile or bar of the keeper, which wheel or roller, then revolving freely, causes the bolt to recede into the case of the lock, and then spring forward into its place in the keeper more easily, pleasantly, and certainly than with the ordinary keeper bar operating by friction only upon the spring bolt. *Patent abandoned.*

229. J. Fyfe. *Improvements in safety apparatus for steam boilers.* Dated January 26, 1863.

In one modification of this apparatus, there is a chest of a rectangular or other convenient form, arranged to be secured to the outside of the boiler in such a position that the proper water surface line may cross it about the middle of its height. A pipe and stop-cock connection is formed between the top of this chest and the steam space of the boiler, and a similar connection is formed between the bottom of the chest and the water space of the boiler. The water level in the chest will thus be the same as in the boiler. To the front of, and communicating with, the chest, there is applied a glass level or gauge tube of the ordinary kind, with a blow-off cock at the bottom. To the upper part of the chest there is fitted a pressure gauge of any convenient kind, whilst upon the top of the chest there is fitted an alarm whistle, or other convenient alarm instrument, arranged to be worked by steam. The bottom of the chest is provided with a valve seat upon the inlet opening of the water-connection with the boiler, and a valve to close the opening is suspended to the float inside the chest. A rod passes upwards from this float, and its upper end is shaped to close the opening communicating with the alarm above. The float rod is also jointed to a lever centred on to a stud or arm, and from the opposite end of this lever is suspended a second float, which is altogether in the steam when the water level is at its proper height. If the water level becomes too low, the alarm valve is opened by the descent of the lower float, and, if the water level rises, it first closes the alarm valve by the buoyant action of the lower float; but on its rising so as to act on the upper float, the action is reversed, and the alarm valve is opened as before. Another valve is arranged in connection with the alarm, and this valve is loaded to the pressure which it is wished not to exceed, so that, on that pressure being passed, the steam passes through the valve and sounds the alarm. *Patent abandoned.*

230. A. Lietout and J. B. Roisin. *Improvements in gymnastical apparatus for medical purposes.* Dated January 26, 1863.

This apparatus consists, chiefly, of a solid rectangular frame, which may be at pleasure either firmly secured to the floor in the vertical position or rest on legs in the horizontal one. In this frame a moveable panel, to which a moveable arm or other chair may be fixed, is allowed to glide up and down or forward and backward in suitable grooves or slots, the panel being kept in equilibrium by means of a counter weight or spring, handles being inserted in a fixed panel for allowing the person sitting on the chair to cause his body and the chair either to ascend or descend, and perform other gymnastical motions counteracted by suitable springs or other elastic bodies, and thus give proper exertion to the principal muscles and moveable articulations of the body, either in the horizontal or the vertical position, whilst rope or other ladders or other gymnastical implements are applied to the standards or uprights of the frame, and even a small apparatus be added for exerting the muscles of the fingers and the hand, which apparatus is arranged in a manner similar to a piano key-board, but with its keys counteracted by suitable springs. *Patent completed.*

231. R. A. Brooman. *Improvements in petticoats or crinolines.* (A communication.) Dated January 26, 1863.

This invention consists in making petticoats of linen, cotton, or other material, cut by preference on the bias, and made to set full at the back by ribbons or strips of steel or other metal, the ends of which are connected to a metal or other hoop carried all round and forming the bottom of the petticoat. With the exception of this bottom hoop there are no hoops or rings round the petticoat, the ribbons or strips of steel or other metal extend diagonally from the hoop at the bottom of the petticoat on one side upwards, and are brought down diagonally and secured to the hoop on the opposite side. The petticoat may be made to open in front, and the sides secured by buttons or other fastenings. *Patent abandoned.*

232. H. H. Henson. *Improvements in fabrics for covering floors, walls, roofs, and other surfaces or objects, which fabrics are also partly applicable to the manufacture of waterproof articles.* Dated January 27, 1863.

One part of the present invention consists in an improved combination of the compounds of india rubber, gutta percha, or substances having similar properties, and cork dust, peat dust, ground leather, ground tan, flock, oxidized oil, boiled oil, gums, resins, umber, litharge, or other similar or fibrous materials, with a certain class of woven, plaited, or netted fabrics of considerable strength and substance, such as cocoa-nut fibre or other matting, the plastic or other compound being applied as an outer coating to one or both sides of the textile fabric. Another part of the invention consists in manufacturing a new fabric consisting of any of the before-mentioned compounds of india rubber, gutta percha, or similar substances, with other materials such as pigments, for forming the under surface of any suitable woven, textile, felted, netted, or other fabric, such as the fabrics called "scrim," "canvas," or "hessian," and any compound of oxidized oil or boiled oil for the upper surface, or *vice versa*, such compound of ozidized or boiled oil being formed by boiling with the oil any description of gums or resins, in greater or less proportions, with an admixture of fibrous or other materials, such as cork dust, peat dust, ground leather, ground tan, flock, litharge, umber, and other pigments, according to the purpose to which the fabric is to be applied. Another part of the invention consists in manufacturing "kamptulicon" of two layers, of which the lower layer is composed of a mixture of Trinidad pitch, india rubber, gutta percha, and cork, whilst the upper layer is composed of india rubber, gutta percha, or similar substances or compounds of oxidized oil or boiled oil, with gums or resins, with the admixture of such materials as are capable of receiving dies, such as flock, cocoa-nut fibre, dust, leather, waste, ground tan, hair, wool, or other similar material. *Patent completed.*

233. G. Davies. *Improvements in preserving provisions and in the apparatus employed in such purposes.* (A communication.) Dated January 27, 1863.

The first part of this invention consists in causing a current of electric fluid to pass through the cases containing the provisions after they are finally closed up; such electric fluid, being made to pass along a fine iron or other metallic wire through the case, causes the wire to become red hot and consume the oxygen. Another improvement consists in placing inside the case (and in connection with the thin wire) any known chemical agent (such as common sulphur for instance), which, in its ordinary state, has no particular affinity for oxygen, but which upon becoming ignited (by means of the electric wire above referred to) evolves any gas (sulphurous acid gas for instance) which will absorb, destroy, or convert into a harmless gas the oxygen which is contained in the case, and which it is desired to get rid of, or the sulphur or other agent may be ignited by any other convenient means. A further improvement in connection with the use of electricty for this purpose is as follows:—After the case has been closed, a sufficient quantity of hydrogen gas is to be introduced therein to form (with the oxygen that may be in the case) an explosive mixture or gas, and this gas is to be then ignited by passing a current of electricity along a metallic wire through the same, and thus all traces of oxygen will be destroyed. *Patent abandoned.*

234. W. Gilpin and J. Kraft. *Improvements in fastenings of umbrellas and parasols.* Dated January 27, 1863.

According to this invention, a fastening is effected which holds the umbrella or parasol in position, whether the same be expanded or closed, by means of a stud fixed in the stick of the said umbrella or parasol, and also of a groove or slot cut in a runner revolving on the stick, and to which runner a notch carrying the ribs of the umbrella or parasol is attached. *Patent abandoned.*

235. C. F. Ash. *Improvements in the manufacture of cornices, joints, and laths of bedsteads and other articles of furniture.* Dated January 27, 1863.

These cornices are made of timber or wood of various shapes and designs, over which thin sheet iron or other metal is securely fastened. Another method consists in manufacturing the cornices entirely of sheet zinc or other metals, which are formed of various designs, and which are obtained by stamping or drawing the metal through a suitable machine to give it the configurations required, and which is intended to give a massive appearance, combined with great strength, lightness, and durability to articles so constructed. The joints are formed of a wrought or cast hollow metal block, with recesses, notches, or mortises formed therein of the same shape or section at the ends of the rails intended to be attached, and to which block is attached a bolt or pin with a nut or substance fitted to the same, the bolt or pin being fastened in its place either by casting to a portion of the metal block, or by welding, screwing, soldering, or pinning it in its position. The nut or other substance when fixed in its place enables the inventor to obtain an equal bearing of the rails in conjunction with a more regular strain of the various parts. The side and end rails are so formed at their ends as to fit one over the other, with a hole punched or drilled in each end which allows them to drop vertically over the upright pin or bolt, and fit into the recesses, notches, or mortises formed in the metal block. The bottom or lower portion of the top pillow is provided with a screwed base, and acts as a nut, which upon being screwed to the pin in the block, and coming in contact with the side and end rails, connects the various parts firmly together. Occasionally he attaches the pin in the top member of the post or pillar, and screws the same downwards into a suitable screw nut provided in the hollow metal block with the loose nut or substance, as the case may be. The method of attaching the pillars or posts to the block and screwed base or nut is by casting to or on to the same, or by soldering, welding, pinning, screwing, or wedging to the pillar or post, as the case may be.—*Patent abandoned.*

236. C. Askew. *An improved railway chair and joint for rails on railways.* Dated January 27, 1863.

This chair is constructed in two parts, and each has a head similar to the jaw of a vice to fit the rail; one of such parts has a sliding groove, similar to the slide of a slide rest of a lathe, and the other has a sliding piece to fit and slide in each groove. When a single or double-headed rail is placed between the jaws of a chair, it is secured in the required position by means of one or more bolts passed through one or more holes through the two parts of the chair, and, if desired, through the rail also for that purpose, and screwed up securely by means of one or more screw nuts. *Patent abandoned.*

237. W. Rollason. *Improvements in the manufacture of metallic boxes.* Dated January 27, 1863.

This invention has for its object improvements in metal boxes, cases, or holders for containing lucifer matches and other lights, and for other purposes, and consists in so shaping and forming the plates of which the said boxes are made that the joints at the angles formed by the junction of the sides and ends are self-acting or self-securing, when fitted and pressed together, forming a box or case without requiring the angles to be soldered or otherwise fastened by any additional matter. *Patent completed.*

238. R. A. W. Green. *Improvements in light-rowing boats, usuallg termed wager-boats.* Dated January 27, 1863.

According to this invention, the inventor makes light-rowing or wager boats of a circular form from end to end, and tapering off from the middle to a sharp point at each end, being, in fact, like two cones placed base to base. In building this boat there are four stringers or principal timbers which, with the exception of the upper one, are continued from end to end of the boat. These stringers or longitudinal pieces are united by circular frames or timbers of graduated diameter, according to their position in the boat, the largest being in the middle and diminishing towards the ends. For two of these circular ribs he substitutes two solid discs, one being placed immediately forward of the sculler and the other in the position to act as a stretcher or footboard, or a support for the same. Having so constructed the framing of the boat, he then applies the outside covering, which he makes of a thin surface of cedar. The bottom half of the boat he makes in two pieces, extending from the middle to each end, and so as to enclose half the periphery of the boat. These pieces are butted and lapped or half-checked on each other at the junction. The upper part of the framework he covers in the same way. *Patent abandoned.*

239. J. Edmondson and T. Ingram. *Improvements in looms and apparatus for weaving.* Dated January 27, 1863.

The objects of this invention are—1, To render looms self-acting in finding the shed wherein a broken pick is made, or where the full shoot of weft is not introduced, so that, when the loom stops, the required shed will be ready to receive the weft the next shoot. 2, To cause the change boxes in fancy looms to change only when the required number of picks of any particular colour of weft have been woven, notwithstanding the weft having been broken. 3, To throw any required number of picks or shoots of weft into one shed. 4, In continuous looms, or looms that do not require to stop for change of weft (such as for which letters patent were granted to the aforesaid Thomas Ingram, dated the 4th day of April, 1860, No. 861), to provide for the introduction of the changed weft into the proper shed. 5, In the aforesaid continuous looms to cause the weft so introduced to supplement the broken pick or shoot, or to cause the next shoot to commence at or near the point or place in the shed where the broken pick or shoot terminates, or to take out the broken pick of weft so that there shall not be a double shoot in some part of such shed where a pick or shoot is broken. 6, To lessen the friction in the warp when weaving gauze, leno, or other similar cloth, and to dispense with the easing-rod usually applied for that purpose. 7, To thread the weft mechanically through the eye of the shuttle or weft case. *Patent completed.*

240. T. Gordon. *Damping and affixing postage stamps to letters.* Dated January 27, 1863.

This invention is carried out as follows:—The inventor has a tank or reservoir for water encased in wood, metal, or any other suitable material, forming the base; in this he inserts a cotton with sponge attached, communicating by means of a small tube with a perpendicular square box or cylinder on the top of the base, of which there are two—one on the left and one on the right hand side—elevated by means of four small springs, so as to form openings for the reception of the letter. The left-hand box or cylinder contains the sponge; it has also a piston working in a sliding cylinder which, when pressed—the letter being placed in the opening formed as aforesaid—damps the corner of the letter; the right-hand box or cylinder which is portable contains the stamps; by passing the letter from left to right, and pressing the piston as aforesaid, the stamp is fixed firmly and securely to the letter. *Patent abandoned.*

241. D. E. Hughes. *Improvements in means or apparatus for effecting telegraph communications.* Dated January 27, 1863.

This invention relates—1, to means for regulating or governing the motion of apparatus employed when recording telegraphic communication. Upon one of the main axes of such apparatus the patentee applies a fly or balance wheel; and opposite the end of this axis, but held somewhere inclined to it, he applies an elastic and weighted rod, capable of vibrating in a rotary direction when acted upon by an arm or connection from the main axle refered to. The vibrations thus obtained regulate and render uniform the motions of the apparatus without the necessity of an escapement. The position of the weight on the vibrating rod is capable of being regulated to the speed desired. To prevent breakage of this vibrating rod by the extent of its vibrations a pad or friction surface is brought into operation upon a friction band or surface as the vibrations increase, in order to use up the surplus force exerted. 2, The improvements relate to means for facilitating the ready change from one class or character of recorded sign or indication to another,
